Management---The Systematic or Kill-Initiative Type

By E. St. Elmo Lewis *

The present is the second of a series of three articles which deals with the subject of management as exemplified in three different types of men — the strenuous, the systematic and the efficent. The points brought out relative to the useful accomplishment and otherwise of each are worthy of careful study.

SYSTEM is the rut in which some men are proud to live. It is the rut in which the thoughtless run without fear of serious catastrophe. System at its worst, affords the incompetent and indifferent a nice comfortable, easy way of doing things. They progress along the road that has already been marked for them, beaten down and road-rollered by the hundreds of feet of men who have gone before. Automatically, every New Year's Day, salaries are increased a few dollars a week, to the "soldier" as well as the worker. Automatically each one is checked up. If each has followed the system, he is ignored, but if he hasn't, he is called down. Each has learned a set, prescribed way of going through his work until, as the youngster said, "he could play the piano with his eyes shut." Under a systematic management a man doesn't have to think, but he does something and remembers. A great many go through their work just as they eat their meals. They eat them whether they want them or not; so they do their work whether it is useful or not.

When the President's Efficiency Commission investigated the Government Department at Washington, it found that Government workers were making copies of original documents laboriously by hand. By the introduction of a photographic process of making these copies, a 75 per cent. saving of clerical time and 90 per cent. in cost was effected. $242,000 a year was saved. In the handling of public documents, $242,000 also was saved. It was estimated that another $850,000 could be saved annually if the departments would properly standardize the handling and filing of correspondence.

The same discovery applies to the majority of business houses. Each department stands alone. To all intents it is a separate business. This department files correspondence one way, this one has another, that one still another. If four or five departments have correspondence with the same customer or prospect, even about the same thing, it is only rarely that the complete correspondence can be brought together without a very great deal of difficulty and trial. Why? Is it not because the management does not see the business as a whole, however, thorough may be its grasp of details?

*Advertising manager, Burroughs Adding Machine Co., Detroit, Mich.

Improvement Over Rule-of-Thumb Type.

The systematic type of manager is a decided improvement on the rule-of-thumb type. The systematic type recognizes that there are some better methods of getting information about what is going on. It aims to find what is a good way to do things by comparing the results of the good, bad, and indifferent methods of the past. It is making the first step toward finding out the facts about your business. The systematic type of manager has one drawback which is so common as to be almost universal—he is still thinking about things and not about people. To him a system is a chart of accounts, or a bunch of cards, or a vertical file, or a loose-leaf ledger with its accompaniment of books and forms and ideas about their handling, but still it leaves out the human element. He continues to believe that the man element is the uncertain, the unsystematic, the untrainable element. He does not think about men—how to train them — but he simply forces them into the grooves of handling a thing in a so-called systematic fashion. He makes them what he thinks they are—automatons.

System a Humanizer.

System is on the contrary, a machine means to a humanizing end. Its primary purpose is to raise efficiency, and a system that doesn't raise efficiency is fallible, weak, impotent, in the way and a nuisance. The purpose of a system is:—

1.—To keep a true record of what has actually happened.

2.—To keep this record in such terms that the manager may readily translate it into the most productive action.

3.—To insure a reliable, immediate, and accurate record, in order that the manager may determine standards relative to the practice of work, and the conditions surrounding the work, and the operations and their sequence, and fix an adequate reward for the best work.

THE THREE-FOLD REQUIREMENT.

The important thing in management is the realization that we need the strenuous, the systematic and the efficient. We need the strenuous to help fix quantity standards, the systematic to maintain them, and the efficient to still further develop them.

In the highly systematized type of management the man gets caught in the net of a pre-determined method of following the work, and can make no change from it, without dislocating the whole business routine. How often have you heard when you go into a retail store and you ask them to do something — "Well, we have never done it that way?" I once made a purchase of some hundred odd dollars in a jewelry store and asked them to deliver the purchase to a steamer. The clerk said that "The delivery doesn't go out until three o'clock." I had to have it delivered at two. In his routine way of thinking it never occurred to the clerk that he could have a special messenger do the delivering, and even the head salesman had to "see if it could be done."

Harrington Emerson tells the story of a systematic government official. When he was living in Germany, there were only four official religions—Reformed, Lutheran, Catholic and Jewish. When Mr. Emerson was filling out the census blank for his father's family, he told the census official he wasn't a member of any one of these four faiths, but he was told that he had to choose one of them or else be fined. Of course he chose!

In a business with which I was at one time connected there was a certain chart of accounts arranged, and you had to select which of these accounts a disbursement was to be charged. New conditions arose, but the chart of accounts remained the same. Items, for instance, such as were used for the development of the sales organization were charged to advertising accounts, and the management of the company, therefore, got an entirely erroneous idea of the amount of money it was spending for advertising. Nearly a sixth of the amount of money charged to the advertising accounts never even remotely affected the state of mind of the prospective purchaser. The consequence was that the chart of accounts ran the business, and not the business the chart of accounts.

Relies on Precedent.

The systematic type of mind constantly falls back for precedent—it is traditional. H. G. Wells, in his thought-provoking book, "The Discovery of the Future," hits off this type of mind remarkably well.

The systematic type of mind.—One might speak of as the legal or submissive type of mind. because the business, the practice, and the training of a lawyer disposes him toward it; he of all men must adhere constantly to the law made, the right established, the precedent set, and consistently ignore or condemn the thing that is only seeking to establish itself.

The efficient type of mind.—I might for contrast call the legislative organizing, or masterful type, because it is perpetually attacking and altering the established order of things, perpetually falling away from respect for what the past has given us. It sees the world as one great workshop, and the present is no more than material for the future, for the thing that is yet destined to be. It is in the active mood of thought, while the former is in the passive; it is the mind of youth, it is the mind more manifest among the western nations, while the former is the mind of age, the mind of the Oriental.

The Needed Combination.

Now, the important thing in management is to realize that we need the strenuous, we need the systematic, and we need the efficient. We need strenuosity to help fix quantity standards, because when the strenuous man is properly guided and handled, he gets a maximum quantity efficiency; but he must be guided.

The systematic type furnishes those reliable records by which we keep track of efficiency, find it out and establish its standards; but left to itself without guidance, the systematic type of man runs to seed. He becomes petrified in the attitude of changeless superiority. It is only the efficient man that can be left alone, because he will not leave anything alone.

The systematic man, of course, is the stand-pat and conservative mind at work. He prefers to write history rather than prophecy. His mind is set towards the setting instead of the rising sun. He compares to-day's result with yesterday's result, instead of comparing it with the ideal standard of to-morrow. The systematic manager inevitably curtails initiative in the plant, for he sets wage limits instead of work limits. He is not concerned about the value so much as he is concerned with the price.

The efficient man is after what we shall do to be perfect. The systematic man is content if he has properly taken care of to-day in comparison to yesterday. The efficient man is principally concerned in seeing that to-morrow is taken care of in order that to-day will automatically be looked after. Place the systematic man in charge of your cost work. He is perfectly content if he can devise a system that will attach a string to every dollar, with the consequence that in the hands of the small systematic men a cost system rarely gives costs, though it produces a lot of figures.

A Cost Fallacy.

The great fallacy in costs, as some of the efficiency experts have pointed out, is to generalize from the whole to a part, to apply data covering a ten-year period to a lesser period, down to a day. Averages are the pitfalls of the system-mad cost accountant. "The average temperature, or rainfall, ought not to be taken as the weather indication for an outing," is the witty way Mr. Emerson has put this failing.

Mr. Emerson in his book brings out one very important item by a very vivid comparison. There is a difference between expense and cost. If a salesman on the road paid 25 cents for a cigar with a hundred-dollar bill and neglected to get the change, the trip cost you $100, but the expense was only 25 cents for the cigar. The systematic cost man wants only to know what becomes of the money, the material and the work where it has gone. The efficient man wants to know what you have gotten for the money, and vitally important, if what you received in return for the money is worth the price. We have crude so-called cost systems which do not reflect the activities of a business at all. Merely because a man is systematic, merely because he has a system, is no indication that the system is telling him any useable facts about his business.

Establishing a Cost System.

It is important, therefore, in the establishment of a cost system to pre-determine what you want it to do. You can't let a cost system just grow. If you do let it grow, it will grow in many ways that will be expensive and bristling with misinformation pitfalls for your unwary judgment. Put in a cost system by all means. Bring to bear upon the problem the same concrete information, skill, experience and attention to scientific detail you would in making an installation of an electric power plant or a transmission system, or putting up a new factory building.

As a matter of fact, what do you know about the matter of costs? What do you want a cost system to tell you? If you want to have a cost system to help produce a greater efficiency, then you want it to aid in a real managerial function. If you want it merely as a supplementary historical record to be tied into your accounts, then a mere cost system will do. But make no mistake; that kind of a cost system will give precious little aid in raising the efficiency of management.

The cost system that doesn't tie up with production standards; that doesn't show how closely you have come to realizing the best way of doing anything; in other words, that doesn't give values as well as costs, is a misnomer, and one that is destined to breed narrow, cribbed and inefficient management. Therefore, any cost system should be, as Mr. Emerson points out, so arranged that it gives:

1.—To the comptroller—information that will show him where the money goes.

2.—To the efficiency engineer—information to show him whether standards are being realized.

3.—To the manager—information to show him where his losses are occurring and his highest efficiencies are being realized.

In order to do this. Mr. Emerson contines: "The requisition system must be materially increased. You apply requisitions to materials—why shouldn't you apply them to personal services and other charges?"

The Method and Manner of Laying-out Plates

By Joseph W. Ross

The laying out of plates to form the various shapes for which sheet metal parts are used involves difficulties that are only discovered when such a job is undertaken. It is well known to superintendents and foremen that some men require much more time than others to do this work in which system and right methods are the great economizers.

PLANE or flat surfaces are generally fairly easy to lay out. It really amounts to marking off on the plates the full-size dimensions as given on the smaller scale of the blue print or drawing. For example, it is required to make a hopper or bin with open top, as shown in the parallel perspective drawing. Fig. 1. The material consists of ¼-in. plate, 2 in. x 2 in. x ¼ in. angle, and ½-in. rivets.

The projection or working drawing

from which he would obtain his dimensions, is shown in Figs. (2), (3), and (4); Fig. 2 being the plan, Fig. 3 the elevation, and Fig. 4 the profile or side

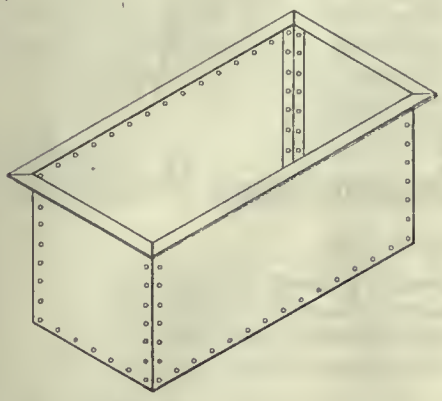

FIG. 1. PERSPECTIVE VIEW OF TANK.

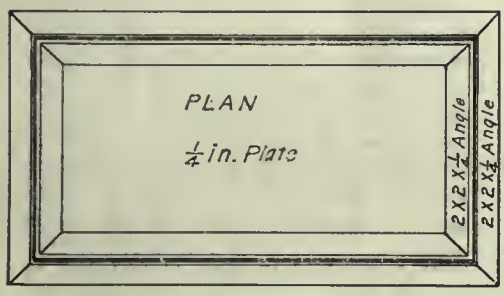
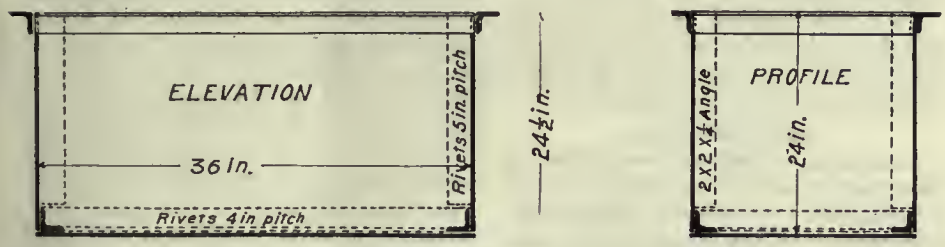
view. The internal dimensions are 3 feet long, 2 feet wide and 2 feet deep.

The bottom plate will be marked off first, and as the bottom edges of the sides and end plates rest on the bottom





FIGS. 2, 3, 4—TANK AS SHOWN ON BLUE PRINT.

plate, and the edges of the bottom plate are flush with the ends and sides, the length and width of the bottom plate will be 36½ in, by 24½ in., which is ½

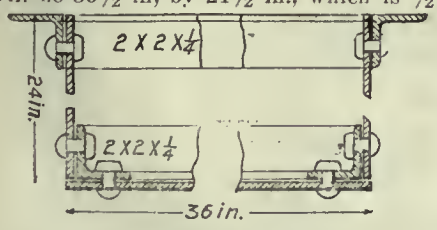


FIG. 5. ARRANGEMENT OF ANGLES, SIDE AND BOTTOM PLATES.

in. wider and longer than the internal dimensions. This is illustrated in enlarged sketches, Figs. 5 and 6.

Mark off a line 36½ in. long lengthwise the sheet, and parallel to this line mark off the rivet line a distance equal to the thickness of the side or end plates plus the distance from the heel of the angle to the hole centers, which, in this case, equals ¼ in. plus 1⅛ in., or 1⅜ in. See Figs. 5 and 6. This gives the rivet line. On this, measure exactly 36½ inches; bisect to obtain center and square up the plate as explained in article I on this subject.

The plate squared up will appear as shown in Fig. 7. The rivets are spaced

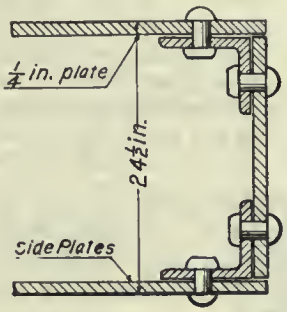

FIG. 6. DETAIL OF BOTTOM JOINTS.

off 4 inches apart with the dividers, in one direction from the center line. Obtain a thin wooden strip or lath and transfer these hole centers to it, then swing the lath to the other side of the center line, keeping the same center line of the lath to the center line of the plate and transfer the hole centers from it to the plate. This makes the hole centers at each side of the center line exactly equal or universal. Now transfer all the hole centers to the lath, place the lath on the opposite rivet line and mark off all the hole centers, care being taken that the center of the lath is exactly on the center line of the plate. Hold this lath for further marking of the side plates and angle iron, and call it lath 1.

Bisect the line BD, Fig. 7, and mark off two equal spaces from center line. In this case, the spaces will equal 5 ins. These should be marked on another lath and transferred across the center line as in the previous operation. Transfer all the hole centers to its opposite side, thus giving all the necessary holes in the bottom plate. Call this last lath 2.

This method of laying out makes the side and end plates interchangeable; that is to say, the plates may be assembled right or left, also, all the plates and angles may be marked off and punched before assembling any of the parts. Examination of the drawing

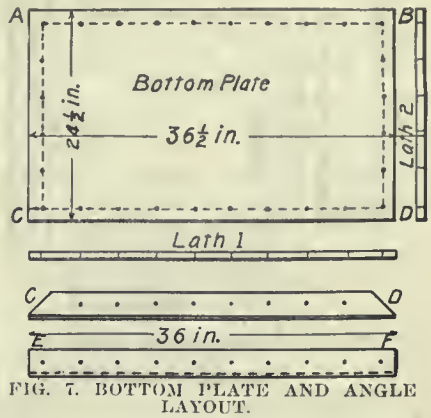

FIG. 7. BOTTOM PLATE AND ANGLE LAYOUT.

shows the side plates to be of the same length as the bottom and their height 24 inches, which is the internal depth of the tank. This plate will therefore be 36½ inches by 24 inches.

As the angle iron comes flush with the edge of the side plate, the rivet line EF will be 1⅛ in. from its edge. Mark off this line; bisect and square up. With the long lath that we marked off the bottom plate (lath 1), transfer all holes from lath to the line, working in every case from the plate center line. As the side plates cover up the edges of the end plates, the vertical rivet lines EG and FH will be a distance equal to ¼ in., plus 1⅛ in. from the plate edge. Space off the holes as per drawing, making both vertical rivet line spacings the same. Lay off the rivet holes at the top to the desired pitch in a similar manner.

After this plate is punched, it may be placed on top of the opposite side plate, and the holes marked through, thus insuring uniformity in both. The end plates, as shown in the side elevation view, will be marked off next. All the angles are flush with the edge of the plate, therefore all the rivet lines will be 1⅛ ins. from the edge.

Mark off the bottom rivet line 1⅛ ins. from the edge; bisect, square up and

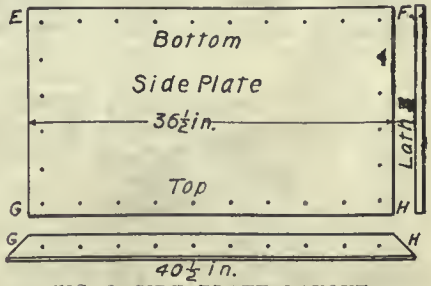

FIG 8. SIDE PLATE LAYOUT.

transfer the hole centers from lath 2 to this line. Use lath 2 also for the opposite side and lath 3 for spacing rivet lines on the sides.

The angles are next to be marked off. The bottom angles at AB and CD are 36 in. long. Mark off the rivet line 1⅛ in. from the heel on both flanges as

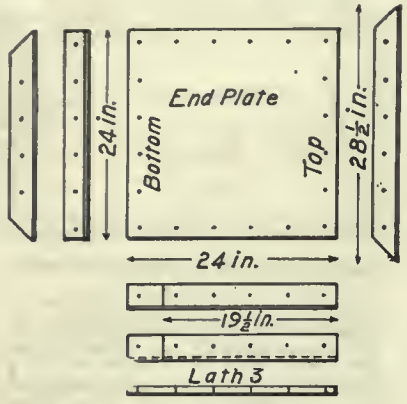

FIG. 9. END PLATE AND ANGLE LAYOUT.

shown in Fig 11. Obtain center, and space the holes with lath 1; equare over center hole to the other flange, and again use lath 1 for marking off the holes. Square over the end holes from one flange to the other as a proof of accuracy. Perform the same operation with the other angles, marking off each line of holes with the proper lath.

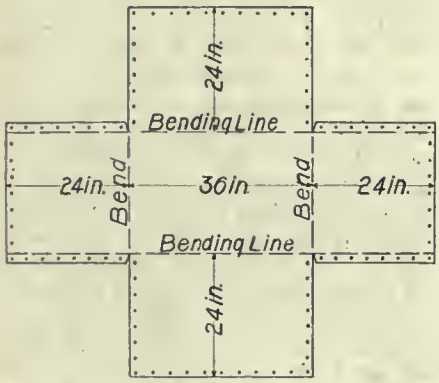

FIG. 10. ARRANGEMENT OF SHEET FOR TANK OF THIN METAL.

If a number of these boxes are to be made, it is advisable to assemble one, and if satisfactory, the plates and angles may then be used as templets, thus insuring uniformity. For a bin constructed of light plate, say 1-16 in. thick, or lighter, a different method would be adopted for laying out. The pattern for

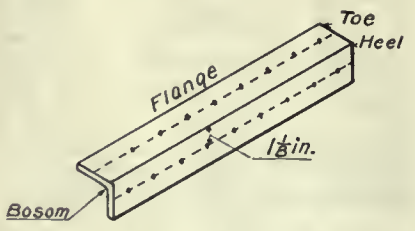

FIG. 11. LAYOUT OF BOTTOM ANGLE.

this is shown in Fig. 10. Mark off on the lower bending line a distance of 36 ins. Bisect and square up, obtaining the four bend lines. Measure up at right angles to these, the widths of the bent-up parts equal to the height of the box. To the lengths of two sides, add the flange parts as shown. Mark off the holes with a suitable lath, making all the sides alike.

Bend over the flanges; proceed to make the long bend, and finally the short bend. If the work be correctly done, the rivet holes will match and the whole will then be ready for riveting. Flat iron, 1 in. or ¾ in. by ⅛ in. may be riveted to the top edges for reinforcement. The heavy bin, if fitted with suitable clevices or wheels, may be used for transportation or trucking purposes. The next article in this series will deal with cylindrical work.

Recent Improvements in Casehardening Practice-II*

By H. L. Heathcote, B.Sc.

The subject matter of this article treats of what has been done relative to case-hardening in the works of the Rudge-Whitworth Co., Coventry, England, and indicates at the same time how the problem presents itself and the manner of seeking a solution.

EXPERIMENTS relative to case-hardening, extending over a considerable time and range of compositions, have confirmed the following suppositions:—

1.—The depth of case depends chiefly on the temperature that the steel attains and the duration of the hot condition. On these factors depend the rate and extent of the diffusion of the carbon or carbide.

(2).—The concentration of the carbon in the case depends chiefly on the activity of the mixture or rate at which it or its products part with carbon to the steel. The concentration of carbon in the surface layers may increase or decrease with temperature, but usually increases as the temperature rises and with the time.

(3).—The duration of the hot condition for a given time of heating depends chiefly upon the permeability to heat of the case-hardening composition.

Exhaustion Tests.

Comparative depth of penetration has been the subject of a number of investigations, but is so much dependent on factors other than the case-hardening composition that the author has sought for some other test. The one finally adopted is to take a known volume of the composition and ascertain the volume of the case that can be got from it without replenishing.

The ratio total volume of case initial volume of case-hardening material, affords a good indication of the efficiency of the composition, and is not so dependent as a single penetration measurement on other factors, such as size of pot, number and size of the articles it contains, loss of heat from furnace walls when the pot is introduced, etc. These exhaustion tests have been made in pots of various sizes, but usually in nickel-plated steel tubes 7 inches long by 1½ inch diameter, and heated in a laboratory muffle for 1½ to 2 hours, starting with the muffle hot. A fresh piece of mild steel, such as ⅜ inch round, is used for each heating, and the period is that required to give, at 900 deg. to 930 deg. C., a case deep enough for commercial use, viz., 0.015 inch to 0.065 inch. Transverse sections are examined microscopically, and the mixture is considered to be exhausted when ferrite bands can be seen between the pearlite grains at the periphery, that is, when the case is unsaturated. With most commercial case-hardening mixtures it is usual to find that the periphery is unsaturated after six or seven heatings of two hours each. The results of testing some experimental mixings are to be found in the following table:—

Mixture.	Ratio Total Volume of Case; Initial Volume of Mixture.
Anthracite 75 per cent., oil 25 per cent.	.....
Anthracite 95 per cent., potassium carbonate 5 per cent.	0.0042
Coke soaked in 10 per cent. aqueous solution of potassium hydrate	0.0048
Anthracite soaked in 10 per cent. aqueous solution of potassium hydrate	0.0061
Anthracite 90 per cent., calcium cyanamide 10 per cent.	0.0109
Crushed bone	0.0122
Anthracite 90 per cent., bone black 10 per cent.	0.0138
Wood charcoal	0.0140
Charcoal 90 per cent., crushed bone 10 per cent.	0.0262
Wood charcoal 90 per cent., calcium cyanamide 10 per cent.	0.0331
Wood charcoal 90 per cent., crushed bone 10 per cent.	0.0368
Bone black	0.0405
Leather charcoal	0.0405
Wood charcoal 90 per cent., bone black 10 per cent.	0.0451
Charcoal soaked in 20 per cent. caustic potsah 90 per cent., crushed bone 10%	0.058
Wood charcoal impregnated with soda ash	0.116

An Improved Case-hardening Composition.

The last mixture in the above table is eminently suitable on the score of permanence, and can be used over and over

*From a paper read before the Iron and Steel Institute.

again indefinitely, provided that the inevitable waste involved in commercial usage is made up from time to time with fresh composition and that the ingredients are well incorporated and in the proper proportions. The author was led to combining charcoal with potassium carbonate, sodium carbonate, and potassium hydrate by the results of tests on charcoal. This rapidly loses its carburizing power. It also contains traces of potassium carbonate, which would react with red-hot charcoal and produce carbon monoxide.

Incorporating a little potassium carbonate with exhausted charcoal is found to restore at once it carburizing power and make it give up its carbon more readily than the original charcoal. The same is true when potassium hydrate or sodium carbonate is incorporated.

Permeability to Heat.

Having found a composition far more permanent in its properties than any then in current use, the author then proceeded to investigate the factors concerned in permeability to heat. Most commercial mixtures consist of or contain a large proportion of small particles which it seems reasonable to expect will block up all the interstices and prevent the free passage of heat, for it has been shown that the heat conductivity of insulating materials depends chiefly on their air spaces. To test this point granular charcoal was employed, and two model case-hardening pots were made 5 inches high, 3.7 inches diameter, and 0.04 inch thick, made of sheet steel and welded together. One contained the charcoal under investigation, and the other was used empty. A thermometer bulb was placed at the center of each pot and the apparatus placed in an oven at 180 deg. C. Two striking points were brought out by this test.

1.—The arrest of temperature at the center at about 100 deg. C. while moisture is being driven off.

2.—The effect of size of grain, and particularly of dust, upon the duration of the arrest.

When the same samples were again heated, the temperature rose much more quickly, the absence of any arrest being, of course, due to the moisture having been expelled during the previous tests. Needless to say, the temperature at the core of a hardening pot will not remain at 100 deg. C. for nearly three hours if the heating be done in a red-hot muffle; but the author has observed that there is an arrest, and another when other volatile matter begins to be given off, when the model pots are filled with oily bone black and heated in red-hot lead at about 850 deg. C.

A mixture which can be used over and over again possesses the great advantage that moisture, oil and other volatile constituents have, for the most part, been already expelled by the previous heatings. The author considers .9 to 1.1 per cent. carbon satisfactory in the composition of the "case."

Methods of Testing Hardness.

So far as the author is aware, very little work has been done to provide commercial means for testing the suitability of case-hardened articles. The practice of examining test-pieces carburized, heat treated, and hardened along with each batch is, of course, sound as far as it goes. The Shore scleroscope and Brinell test have their spheres of usefulness, but still the file is the instrument most used, and perhaps rightly, for it does give an idea of the resistance the surface of the article offers to abrasion under pressure, which is what most articles are case-hardened to withstand. This and the Brinell test are, we believe, the instruments in commonest use for testing case-hardened work and test-pieces.

For small articles the modified center punch is particularly suitable for rapidly getting a working idea as to whether the case is above the minimum permissible depth. It is an ordinary 6-in. Brown & Sharpe automatic center punch to which we have fitted a screwed-on container for holding a ⅛-in. bicycle ball. The hard point has been removed and the container screwed on in its place. The ball protrudes just sufficiently to prevent the container coming into contact with the article under test. This is very useful for large as well as small articles, and its readings appear to refer more to the case and less to the core than those obtained with a Brinell testing machine.

Colors of Hardened Work to Facilitate Viewing.

Many articles, such as cups and cones, cannot be conveniently tested with a scleroscope or sclerometer on account of their shape. Realizing the need for some method which would enable articles of all sorts to be tested in bulk, the author turned his attention to the production of colors on hardened surfaces which would afford an indication of the nature of the steel composing such surfaces. The ordinary solutions employed by the metallographer are unsuitable for commercial application, some because of their inflammability, others because they will not flow evenly over a somewhat oily or greasy surface. A suitable solution which has been found to give satisfactory results consists of:—

Alcohol, 1 liter.

Distilled water, 1 liter.

Nitric acid, pure, 100 cubic centimeters.

Articles ground or polished after hardening and immersed in this for ¼ to 1 minute are stained brown or light blue where the structure is martensitic; dark blue or dark gray where there is troostite; and hardly stained at all on ferrite or pearlite.

By treating hardened articles in this way before viewing, inequalities are rendered visible and can readily be detected. The fact that the whole of the surface is tested, and not merely the parts touched by the file, sclerometer, or scleroscope is an enormous advantage for commercial purposes. The test reveals at once spots that have been splashed before quenching, and contain troostite, also superficial tempering due to a glazed surface on the grinding wheel or to excessive pressure. It does not appear to be possible to obtain a colorimetric scale of hardness in this way, but when a number of articles are dipped at the same time the eye readily detects those that have a different appearance, and all that is then necessary is to check the odd ones with a file or sclerometer. This test is also suitable for tools and complicated articles that cannot conveniently be tested with an instrument. It also shows the depth of case if a part is left on and ground away, and should prove useful for ascertaining whether an article has been properly tempered.

The swinging hammer is the outcome of another attempt to replace the variable muscular force of the tester by the constant force of gravity. Instead of a skilled viewer wielding a hammer we have a boy, and this simple instrument, which consists of an ordinary hammer swinging on a support passing through a bushed hole in the handle. The heavy steel block which carries the support is arranged to admit various holders adapted for receiving, and if necessary clamping, the parts to be tested. It has been found very useful for testing small parts, such as the rollers of motor cycle engine bearings, the blow being controlled by observing the angle on the graduated quadrant behind the hammer.

Calgary, Alta.—Work is now fully under way on the new Government elevator, which will be one of the finest in the Dominion. It is to be located just to the south of the proposed inside stockyards site, and will have a capacity of three-and-a-half million bushels. Mr. Howe, the Government engineer, is at present in Calgary superintending the beginning of operations. The contract was let two weeks ago to Janse Brothers, Boomer, Hughes, & Crane, fifteen months being the time given for the completion of the work. Mr. Crane states, however, that he is confident that the work can be completed considerably within the limit. Besides the elevator proper, there will be storage, separating and cleansing plants, and other buildings.

PRODUCTION METHODS AND DEVICES

A Department for the Interchange and Distribution of Shop and Office Data and Ideas Evolved from Actual Practical Application and Experience

AN UNUSUAL LATHE JOB.

By J. Davies.

SOME time ago at the New Yard Iron Works, Cumberland, it was required to overhaul and re-tube two locomotive boilers. By some unfortunate circumstance it was found that all of the copper tubes ordered for the job had been cut too short by one inch. The foreman, a resourceful Scotchman, devised a means of lengthening them the required amount in a lathe, which proved very successful and satisfactory.

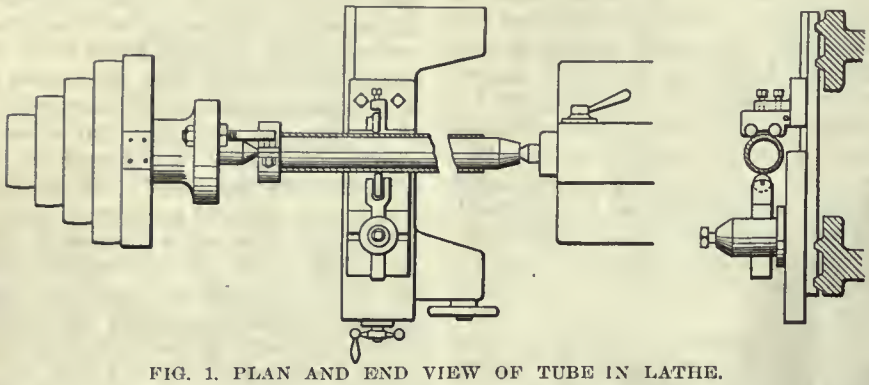

FIG. 1. PLAN AND END VIEW OF TUBE IN LATHE.

A piece of shaft was first prepared as an arbor for the pipe. It was made a light drive fit for the tubes, and was provided with large centers, while the ends were tapered to facilitate placing and removal. The tube being slipped into place, was secured to the arbor by a pair of steel clamps, which also served as a drive. A system of hardened expanding rollers was now prepared, as shown in the end view, Fig. 1, two being supported by an angle bracket at the rear end of the carriage, and a third set up in the tool post. The shapes of the roller faces were varied so as to give the maximum expanding effect. The one for the tool post is shown at (a) Fig. 2, while (b) and (c) represent the rollers in the rear.

The machine was driven at a fairly high speed, and the feed adjusted to four to the inch. The carriage was run back and forth until the tube had stretched to a mark placed on the end of the mandril for the purpose of gauging the length. This process required several passes, leaving a short length on each end untouched, so that the fit in the tube sheet was left intact. After careful annealing, the tubes were placed in the boiler. Whether this treatment had a deteriorating effect upon them or not, we have not been able to determine, but the locomotives have been giving good and constant satisfaction ever since.

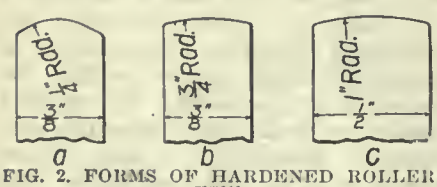

FIG. 2. FORMS OF HARDENED ROLLERS USED.

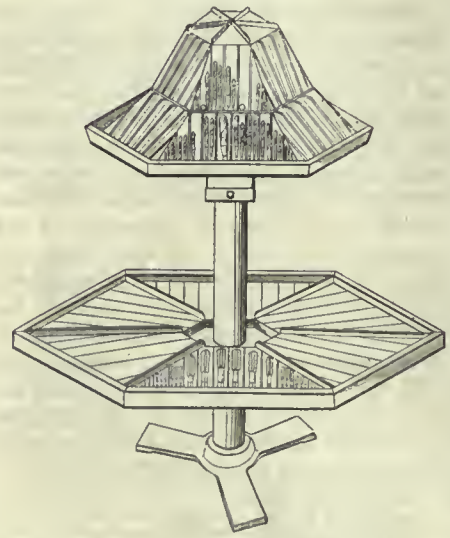
A CONVENIENT TOOL STAND.

By C. I. W.

The accompanying cut illustrates a type of tool rack employed in the toolroom of the Calgary Iron Works for conveniently holding the most used small tools. It consists of two or more hexagonal wooden trays, supported by set collars at suitable heights on a vertical 1 11/16-inch shaft. The trays are suitably partitioned off for the class of tools to be held, and are fastened to large cast iron flanges, which are bored a loose fit for the vertical shaft. An appropriate flange into which the shaft is fastened by means of set screws forms the base which is screwed to the floor. This type of tool holder can be used in places where, on account of lighting and other considerations, an equal amount of shelf space could not be secured in any other way. The stands may be much cheapened by using pipe for standards and pipe flanges to support the trays.



SMALL TOOL STAND.

ADAPTING SAFETY FLANGES TO OLD EMERY WHEEL ARBOR.

By W. Gibbs.

Among the many problems instituted by the safety first campaign in our plant, that in connection with the safetyizing of grinding wheels in the foundry cleaning-room at first offered considerable difficulty. It was decreed that all wheels not completely hooded should be held between flanges extending to within four inches of the periphery of the wheel. As there were a large number of grinding machines already equipped with the small flanges shrunk on or otherwise fastened in place, any radical changes were bound to involve considerable expense. Permanent 10-inch flanges would also render a large part of a rather expensive wheel unusable.

GRINDING WHEEL ARBOR WITH AUXILIARY FLANGES.

The accompanying sketch shows how the change was accomplished. Steel flanges of different sizes were made to fit over the original collars on the arbors. The new wheel is placed in the machine with the largest pair of flanges, and when worn down as far as practical, a smaller set is substituted, and finally the wheel is used up in the small original clamps furnished with the machine. This scheme has proved very satisfactory. The spare clamps are kept hung up in a convenient place, and the change takes little time; besides, complete safety as well as wheel economy is secured.

Better results can be secured by operating the new wheels upon arbors with large flanges, and which are run at suitable speeds. As the wheels are worn down, they may be placed in other machines between flanges of the proper size and run at speeds faster in accordance with the reduced diameters.—Editor.

MANUFACTURE AND USE OF INTERNAL GAUGES.

By Spring Craig.

IT is being recognized more every day that interchangeability and accuracy are two of the most essential features in multiple machine building. One of the most successful firms in the world size all parts of their product to standards, even the outside dimensions of collars and other seemingly unimportant dimensions being accurately maintained. The writer has known of more than one factory in which it cost more to assemble the machine than to manufacture the several parts.

In order to be interchangeable, all pieces must be alike, and gauges play a very important part in getting this desired result. To be sure there are jigs, fixtures, templets, tools and various machines used as well, but the final inspector accepts or discards the work according to the verdict of the gauge.

Without gauges as exact standards of size, each machine must be "fitted" together and the advantages of rapid and unhindered assembling along with interchangeability of parts are entirely lost. With present-day machine shop facilities, the building of but a small number of machines will repay the cost of a set of gauging tools, and, if the plant be properly equipped with standard gauges, the special ones required may be reduced to a comparatively small number. The machine hand provided with a proper gauge accomplishes the "fitting" as well as the production of the general form of the machine component, and as machines are replacing hand work more and more, the parts can in this way go directly from machine hand to assembler.

Many toolmakers attempt to get up a complete set of gauges from the designer's drawings of the machine to be built. Experience has proved this to be a mistake. The correct and most practical way is to build a model or sample machine, which should be made as much as possible to standard gauges with which the shop is regularly equipped.

The standard set of gauges with which a machine shop should be supplied will consist of plug gauges ranging in size from ¼-inch to 3-inch by sixteenths for the various classes of fits likely to be required; and for sizes above this, rod gauges for standard sizes as are needed. The cost of gauges depends largely upon the class of man that makes them, and should be balanced against the cost of the time lost in many ways without their use. It takes considerable time to caliper a hole and then set a micrometer to the caliper, several chances of error existing in the process.

Internal gauges, plug snap and rod can be used in any shop for a large variety of work. The size of the bore or the diameter of reamed holes forms the starting point for most machine operations, and the convenience with which other parts can be fitted to these plays an important part in the harmonious progress of erection.

Material for Gauges.

For plug gauges in a great many shops where there are no case-hardening facilities, tool steel is the only material to use, and in the majority of plants this is used in any case, being thought best by the most experienced gauge makers. Some firms use machine, open hearth and other steels case-hardened. One objection against case-hardened machined steel for plug gauges is that sometimes a soft spot will be left in the surface of the gage. In grinding, this becomes charged with emery and has a tendency to stick in the hole and cause the tool to gauge over size.

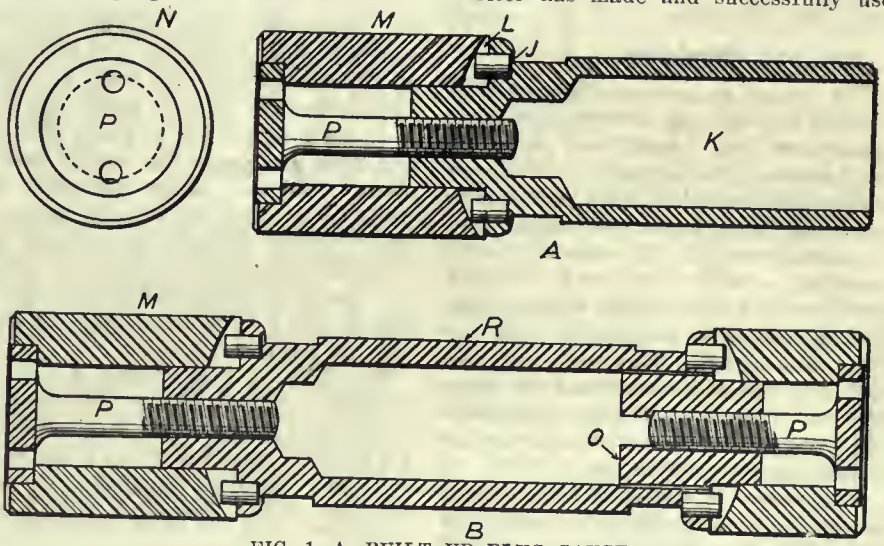


FIG. 1. A—BUILT UP PLUG GAUGE.
B—BUILT UP LIMIT GAUGE.

For snap gauges machine steel is generally used, and gauges can be purchased in the rough in different sizes from any of the leading drop forging manufacturers. Profile and end gauges (rod or pin) are made of machine steel, usually hardened on the ends only, with cyanire or prussiate of potash.

Up to three inches for internal work, the gauges are usually made solid or plug. From three to six inches snap gauges, as shown at C and D, Fig. 2, of which G is an end view, are most used. All sizes above are made in the form of rod gauges, as shown at F, Fig. 3. In most large modern shops the plug gauges are built up for sizes from 1½-inch to 3 inches in diameter, with machine steel handles for economy and lightness, while in others they are made solid, as shown at E.

The stock used should be ⅛ inch larger in diameter than the finished gauge.

Built-up Gauges.

Built-up gauges require but one-third the material needed for solid ones. They are also much lighter to handle, take up less room to store, and one handle may do for five or six sizes. This saves turning and knurling a handle for each gauge.

There are several ways of building them up, one being to have a taper shank projecting from and turned integral with the gauge, on which a handle with a corresponding female taper is driven. This style does not save much stock. Another method is to have a hole bored through the gauge with a slight taper and the handle, having a shank of the same taper, is driven into the gauge. This form has a tendency to split the gauge and both have the objection that the gauges may be injured while being knocked on and off the handles. The writer has made and successfully used built-up plug gauges of the form shown at A, which is a standard, and B, a limit gauge, one end to go and the other not to go. One end was one-half thousands under size and the other one-half thousands over.

The gauges of this set are of tool steel and vary from 2 inches, by sixteenths, to 2½ inches. They are bored one inch, so that one handle does for seven or eight. At the bottom end they are recessed nine thirty-seconds ins. deep to accommodate the screw that holds them to the handle K, Fig. 1.

There is a recess milled in the top at L three-sixteenths in. wide for the pins J in the handle to slip into. These pins are to prevent the handle turning in the gauge. The screws P have two holes drilled in them as shown in A and end view N to facilitate tightening and removal. The handle K is machine steel and is bored out as shown, leaving three-sixteenth walls which are knurled on the outside.

At B in the limit gauge it is made the same, with the difference that after the handle is bored it is threaded internally at the upper end and plug O is screwed in and turned up to fit the gauge, being also tapped for screw P. The pieces of tool steel for the gauges were cut off the right length to finish up for the whole set, and laid aside. When a lathe man was short of work or was waiting for a job, these gauge blanks made very convenient alternatives, and were thus made much more cheaply than might be expected. They were turned twenty thousandths large on the outside and bored about three or four thousandths small. The reason for the latter procedure was to get a true hole and thus prevent any possible moving on the arbor during grinding. Another reason was that surprisingly little pressure on the inside distorts the gauge, and a plug gauge that is not absolutely round will give a great deal of trouble.

Hardening.

The turned gauges were heated to a dull red and set aside to cool. For hardening, they were heated very slowly to the hardening temperature, then dipped and kept in the water until cool enough to be held in the hand. As soon as they werewithdrawn from the water they were sprinkled with lard oil and reheated until the lard oil smoked, which condition represents a pale straw color or about 430 deg. F. They were then immediately dropped into oil and left there to cool. The gauges were afterwards put away to season for about a month before being ground to size.

The centers in the solid plug gauges up to 1¼ inches in diameter require to be lapped, after being hardened, with a piece of brass turned sixty degrees and used in the drill press, with emery powder. This cleans them out, making them run true on centers. The same care should be observed with the mandrils on which the built-up plug gauges are ground. In grinding, the gauge and mandril must turn on dead centers; that is, neither center should revolve. If the grinding is done dry, the gauge should be cooled to the room temperature before removing the last thousandth. A difference in temperature will cause a difference in size from one-tenth of a thousand to four-tenths. They should be left preferably one-tenth of a thousandth over size rather than any amount under, on account of wear, this being plenty close enough for most work. To get them closer to size than this they would have to be measured by a measuring machine, an instrument not possessed by one shop in one hundred. After being ground, if a medium smooth piece of emery paper is rubbed over them while running at high speed, it will give a glass finish and make the gauge wear better.

The micrometer used should be set to standard gauges and should read in ten-thousandths, although some toolmakers can get very close with those reading in thousandths. The gauges werebeveled 45 degrees on the front end to help to start them easily into holes, and on the back a slight radius is turned to prevent them being injured.

The snap or flat and rod gauges have to be case-hardened. In using them they

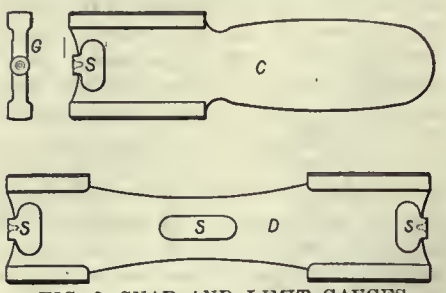

FIG. 2. SNAP AND LIMIT GAUGES.

are deceiving in that a hole bored to standard plug gauge size will fit loosely on the corresponding flat gauge C, Fig. 2. The amount that the flat gauge will have to be made larger will be about .0004 in., and for a rod gauge the amount will be about .0006 in. Most mechanics will readily recognize this through using ordinary spring calipers, as the hole has to be bored so that one end of the caliper will swing back and forth in the hole slightly for a fit in order that the shaft will go without driving.

The flats S, Figs. 2 and 3, are for stamping number and size. For measuring the rod gauges, a two-foot vernier is the handiest way, but if one is not available, two parallels clamped to a scale and set with a magnifying glass will

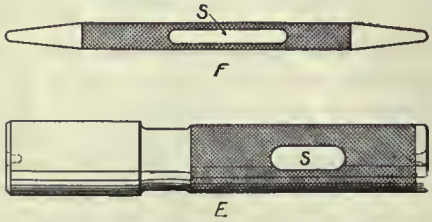

FIG. 3. ROD AND PLUG GAUGES.

come close enough for the majority of large work. If inside micrometers are obtainable, the parallels can be set more nearly the right distance apart. For the larger rod gauges, the scale and parallels are often used, and a good, careful mechanic can get very accurate results with a reliable scale.

RULES FOR ELECTRIC CRANEMEN.

1.—Never go on top of crane, or permit anyone else to do so, without opening main switch and placing warning sign or lock on it. Do not close same until you are absolutely sure there is no one on crane or crane runway who might be caught.

2.—Before racking carriage or moving crane bridge, be sure that hook and chains are high enough to clear all obstacles.

3.—Under no circumstances permit your crane to bump another crane until you are positive that no one on the other crane is in a position to be injured.

4.—Examine your crane every turn for loose or defective gears, keys, runways, railings, warning bells, signs, switches, sweepbrushes, cables, etc., and report any defects to foreman. Keep crane clean and well lubricated. Report to foreman any repairs which you cannot handle promptly.

5.—After completion of any repair job, make sure that bolts, tools, etc., have been removed so that no damage to machinery will result when crane is started, and so that nothing can fall off. Keep tools, oilcans and other loose objects in box provided for that purpose.

6.—Warning signs provided in cabs should be used when crane is under repairs.

7.—When there are more than two cranes on the same runway there shall be provided stops at a suitable location near the center of the runway for the purpose of isolating a crane while repairs are being made on same.

8.—Do not carry load over men on floor, use warning gong to attract their attention.

9.—Do not allow men to ride on load carried by crane, nor on crane hooks.

10.—Do not move load without signal from proper authority.

11.—Do not take any side lifts.

12.—Do not hoist any job that you consider insecurely slung.

13.—When handling heavy loads, particularly hot metal, test hoist brake by throwing to "off" position after load has been lifted a few inches; if brake does not hold, do not move crane until it has been repaired or adjusted.

14.—Do not carry objects up and down ladders, use rope for handling anything too large to go into pocket.

15.—When on duty, remain in cage for prompt service.

16.—Do not forget that bumpers are put on for emergency and not for everyday use.

17.—Crane operators must be absolutely sure that all controller handles are on the "off" position before closing switch.

18.—Do not, under any circumstances, reverse controllers, except in an attempt to prevent accidents.

19.—Emergency cutouts should be tested at least once each day.

20.—Cranemen must not use controllers to supply heat to cage.

21.—On all cranes equipped with the grindstone type of controllers and having main and auxiliary hoists, when either hoist is at rest, controller handle must be removed to prevent accidental starting of same.

EFFICIENCY IN THE ENGINEERING BUSINESS.—I.

By "Onlooker."

THERE is a saying, which contains more than a little truth, to the effect that lookers-on frequently see most of the game. This is a truism that is particularly applicable to business in general, and a realization of its significance has led to the evolution of the efficiency expert in the modern industrial world. It is also applicable very particularly to the engineering profession, which offers a wide field to the expert on account of the many factors which enter into the business of converting crude ore into highly-finished and accurate machinery. The manager of a foundry, of a factory producing steam engines or boiler fittings, or any other specialized product, is apt to argue that he knows more about his own business than an outside engineer can possibly learn in a few weeks or a few months, and in this he is doubtless right; yet the efficiency expert is the looker-on, who sometimes sees most of the game. The manager himself is often too near his operations, too intimately associated with the running of his business, to take a comprehensive and unbiased view of the whole.

Sometimes he has, through long connection with a particular factory, got into a rut, and almost always there are phases of the business to which he has failed to give sufficient attention. He may be an excellent and up-to-date practical engineer, and yet fail through neglecting the advertising and selling end of the business, or through disregarding the importance of an accurate system of keeping costs. On the other hand, he may be a first-class business man and fall down on the producing end. In either case the business will suffer, and in either case a good efficiency expert, bringing to the problem the clear sight of an outsider, will be able to diagnose the malady and prescribe a remedy. Many liquidations might have been avoided by the timely calling of authoritative advice.

Importance of Small Things.

In this, and in the subsequent articles of this series which will appear from time to time in Canadian Machinery, the writer will endeavor to point out some of the commoner failings which have come to his notice during the course of his experience as an efficiency engineer, and to give a few hints which may be of value to those in charge of engineering shops.

One of the most important points in the running of an engineering concern, and one most frequently overlooked, is the importance of small things. The main processes are usually systematized. It is the little things that get neglected; the systematic filing of drawings and storing of patterns, the orderly arrragement of tool rooms and material stores, the efficiency of the power equipment or the accuracy of the accounting and costing departments. Yet it is the aggregate of such small negligences which count in the long run. It is the small leakages remaining unnoticed that sink the ship, and much of our space will, therefore, be devoted to a review of things small in themselves, but important in their aggregate.

Drawing Office and Designing Departments.

Since every product of the engineering works has its inception in the drawing office and designing departments, these will afford a good starting point. It is a fact that very few drawing offices are efficient in equipment, especially as regards small instruments. Every draughtsman should have a complete set of instruments in the best possible condition. No inferior or damaged draughting tools should be permitted. Every man, moreover, who has any designing to do and who does not work entirely from rough-dimensioned sketches, should have a reliable slide rule, while a fuller should be available for cases where particular accuracy is required. Logarithms are clumsy and slow, and arithmetical work has no place in the up-to-date office. The time saved by good equipment in the drawing office will rapidly repay the relatively small expense of the instruments required, and yet many managers who will spend thousands on a new machine tool will allow their draughtsmen to work for years with poor implements.

If the shop be of any size, an arc light printing apparatus is almost essential. Blue prints can be made outside, but they cost more, and delivery is sometimes slow. Time and money alike are saved by having the prints made on the premises.

Filing of Drawings.

The filing of drawings is an important matter. Much time is saved by the ability to rapidly turn up a drawing. They should be filed flat, in shallow drawers, and each drawer should have or the outside the numbers of the drawings it contains. If a firm is turning out gas engines or any similar product the best way is to have all the drawings embraced in a given type filed together, and to have a reference card giving the number of the drawing for any given part. The drawings should be numbered on the bottom left-hand corner. All that is then necessary to find any given sheet is to refer to the card and turn over the corners of the drawings until the desired number is found. The return of all drawings to their correct drawer is a matter which the chief draughtsman should insist upon rigorously.

Where drawings are more diverse, such as in the case of a factory turning out a wide range of, say, valves and steam fittings, the problem of filing becomes more difficult. A good practice, however, is to give to every valve a letter and a number. Thus a spring loaded safety valve may be designated as A, the different sizes of that particular type being numbered 1, 2, 3, and so on. This designation so given in the catalogues, to facilitate ordering, is used in the shop and in the finished store. The drawings are then filed consecutively, both alphabetically and numerically, under each letter. The various drawings connected with a given fitting, if more than one sheet is required, can be fastened together. All then required in order to turn up the drawings of any fitting is a reference list giving the letter, the number and the corresponding description of valve required. An office boy can then find the drawing, and save a draughtsman's time. A fireproof vault should be used for the storage of drawings where these are of particular value, as the replacing of drawings in the event of fire in the office is a long and costly process.

The Chief Draughtsman.

A good chief draughtsman is an asset to the organization of a firm, the value of which cannot be estimated in dollars. He can, by cheapening designs, without lessening the efficiency of the finished article, save many thousand dollars annually. Frequently it happens that he can, by slightly changing designs, adapt existing parts to new articles, thus cheapening production by rendering possible the utilization of existing patterns

and increasing economy by the multiplication of repetition work.

Checking calculations in design work is important. Usually a designer checks over a second time his own original work. It takes him as long to do so, or nearly as long, as it would take another man to do the work, and he is more liable to repeat his original mistake, if there be one, than another would be. It is, therefore, advisable, where possible, to have all work pass through two hands, and to make the two men jointly responsible for the accuracy of the calculations. Mistakes in the designing or draughting department are apt to be very costly; it is, therefore, advisable to get together a reliable set of men and to keep them. A good man is worth paying always, and never more so than when he is in the department where the product of a plant is conceived. It is a good thing to encourage suggestions from the office staff. A draughtsman may not be as experienced as his manager, but he is intimate with his own work, and can frequently see further into it than those of greater experience and less intimacy. We all have much to learn, and all may, at times, be taught even by subordinates.

CHEMICAL ANALYSIS IN THE FOUNDRY.

By R. Micks.

IN the last few years the foundry has made rapid strides in the way of improving the quality and quantity of their output, and to my mind the most important of all these improvements and changes is the introduction of chemical analysis of the constituents. The old system of judging the mixture by the fracture of the test bar was all right up to a certain point. If the fracture looked all right, everything was O.K., but if it showed sulphur blow holes or other defects how was a foreman or foundry superintendent to know whether to blame the pig iron, scrap, or coke, unless he had the analysis of each and knows how to mix materials accordingly. Right here is where the chemist comes in, for he can trace the trouble, advise how to overcome it and save dollars, both in foundry and machine shop. You are sure of your mixture when you follow his advice, otherwise it is mostly guesswork, and that does not pay in an up-to-date business.

Every foundry should have enough iron and coke on stock so as to be able to get the analysis of new cars of iron or coke before it is necessary to use the latter.

Chemical analysis has come to stay.

In a few years, the air furnace will take the place of the cupola in all large machinery foundries and it is impossible to get your mixture right with these furnaces without the chemist's help. There are still a lot of foundrymen who do not consider chemical analysis practical, but I do not think it will be long before the most conservative of them will be won over. No matter how small or how large their foundry, chemical analysis will save many dollars, reduce loss and give a better quality of castings.

ATTRACTIVE FEATURES OF EMPLOYEES.

By A. E. S.

To the foreman and superintendent, the self-reliant man who thoroughly knows his business and at the same time accomplishes a reasonable amount of useful work, embodies the essential requirements of the ideal employee, and is, therefore, the type most sought.

While this is no doubt true, and if these qualities could be accurately defined and located, a very large number of officials would consider their worst problem solved; still, men who are most popular with the management, the men who receive the greatest number of promotions, are often decidedly lacking in one or more of the above features. To other industrious and conscientious, though more or less thoughtless men, the advancement of their seemingly less deserving companions arouses a sense of heart-burning and dissatisfaction.

The actual performing of one's daily work usually falls considerably short of what a subordinate should do for the man above him. His duty to a foreman should be at least humanitarian; besides, there is surely no harm in studying the disposition of the man above even to the extent of catering to his likes and avoiding his dislikes. Many foremen are decidedly crabbed and disagreeable, but workmen should not forget that this is largely the product of the treatment accorded him, and that he himself has a responsibility in this connection.

How often is the pronounced ability to do spectacular things offset by the habit of showing off to the man some stages higher up than the boss. The best man is he who finds pleasure in his work while he is at it, and the most disagreeable is the man who seems to find amusement in making someone else as uncomfortable as possible.

The ability to undertake the most difficult jobs with peculiar earnestness, the faculty of doing a little more than is expected, and the capacity to put a bit of humor in the barren spots of the day's routine are little rays of sunshine that will not only be reflected in those coming into immediate contact, but will be multiplied in him who is their disseminator. The man who is considerate of his immediate superior is the one who eventually becomes a welcomed associate.

ENORMOUS WASTE OF COAL.

Speaking before the Royal Society of Canada recently, Dr. F. D. Adams said: Perhaps the most serious waste which is taking place in our Dominion at the present time in connection with its mineral resources is presented by the mining and utilization of coal. In the first place, in mining a coal seam, from 50 to 90 per cent. of the coal is left in the workings for the purpose of supporting the roof. Of the coal which is taken out and burned under boilers in the usual manner, only about 12 per cent. of the total energy is developed. That is to say, we secure for useful purposes only about 5 per cent. of the total energy contained in the coal contained in the area. If the coal is burned in gas producers and the gas so obtained used in internal combustion engines, these, having a higher efficiency, develop about 30 per cent. of the energy in the coal actually mined, or about 12 per cent. of the energy locked up in the coal of the whole area. This is an improvement, but still represents an enormous waste.

On the other hand, coal may be mined for the production of coke for metallurgical uses. About three-fourths of the coke produced for this purpose in North America and all the coke made in Western Canada is manufactured in beehive furnaces, which yield a relatively low percentage of coke, while the other products of the coal—gas, tar, ammonia, benzol, etc.—go to waste. All these products may be saved by making the coke in by-product ovens, representing in localities where the surplus gas can be sold at a reasonable rate, a gain which is estimated by Mr. F. E. Lucas, manager of the coke ovens of the Dominion Coal Co., at $1.98 per ton of coke made. This figure will, of course, vary with the locality in which the coke is produced, but it emphasizes the great saving which may be effected by the use of the modern by-product oven.

The tar and ammonia obtained by this process, moreover, meet with a ready market. The former is already being used extensively in the Dominion for a variety of purposes—among them as a binding material in the manufacture of briquettes from slack coal, thus enabling this waste product to be successfully utilized—while the ammonia is a fertilizer of the greatest value, for which there is great demand abroad and for which an ever-increasing demand will arise in Canada as the necessity of employing improved methods of agriculture is brought home to farmers.

Arithmetic for the Machinist and Workshop Operative

By J. H. Rodgers

With the further development of this course in arithmetic, it will be found by those who have followed the introductory lessons and profited by them that the various practical applications resulting from the succeeding lessons will be easily observed and their time and labor-saving features so appreciated as to be adopted at every available opportunity.

THREAD CUTTING.

THE elements of thread cutting and the procedure to be adopted when cutting single threads were dealt with and explained in our issue of June 25. In the present instance, double, triple, square threads, etc., are featured, allowing thereby in the combination of the two articles quite an intelligent and comprehensive grasp to be had of this important factor of machine shop practice.

To cut 30 threads per inch with a 4-thread lead screw, gears increasing by 4 from 24, being available.

Ratio=4:30=1:7½.

Using gear of 24 teeth on stud we have

$$D=\frac{A\times T}{L}=\frac{24\times 30}{4}=180 \text{ teeth.}$$

To compound the train. Dividing 180 by 3, we get 60 for the gear on the lead screw. Now, the intermediate gears must have a ratio of 3:1, or 84:28, therefore,

$$T=\frac{B\times D\times L}{A\times C}=\frac{84\times 60\times 4}{24\times 28}=30 \text{ thds.}$$

Care must be taken when cutting threads that the lead is not confused with the pitch. The pitch of the screw is the distance between the centers of two adjacent threads, while the lead is the advance in one revolution of the screw.

While the pitch and the lead are the same in single cut threads, the lead in a double thread is twice the pitch; in a triple thread, three times the pitch, etc. Chart 24 shows a single cut left-hand thread, and a double cut right-hand thread.

To cut a double thread ¼-in. pitch with a 4-thread lead screw, gears increasing by 5 from 20. When cutting threads other than single, the lead must be considered when calculating gear wheels. In this case the lead is ¼ in. x 2=½ in. or two turns per inch.

It is obvious that the saddle must travel ½ inch (two turns of the lead screw), while the lathe spindle—or work—makes one revolution.

Ratio = 4:2 = 2:1.

Multiplying both terms of the ratio by 10, we get 40:20, or by 12½ we get 50:25, or by 15 we get 60:30. Any of these pairs will be suitable wheels.

To cut a triple thread having a lead of 1¼ in. with a 2-thread lead screw, gears increasing by 4 from 24, the turns or threads per inch are found by dividing 1 by the lead of the screw, as

$$\frac{1}{1\frac{1}{4}}=1\times\frac{4}{5}=.8,$$ then ratio=2.8, or,

as was shown in a previous lesson, that multiplying both terms of a ratio by the same number does not alter its value; then multiplying both terms by 5 we get 10:4 as a new ratio.

Now, if we had gears of 10 and 4 teeth respectively they would give the desired result; but as such gears are practically impossible, we must continue the calculation further for proper wheels. Therefore, multiplying the new ratio by a number, say, 8, or the original ratio by 40, we get 80 and 32 as the required gears.

Proof—Threads per inch on lead screw multiplied by gear on lead screw equal threads per inch on the work multiplied by gear on stud; or by formula (chart 22).

$$T=\frac{L\times D}{A}=\frac{2\times 32}{80}=\frac{8}{10}=.8$$

$$\text{Lead}=\frac{1}{.8}=1\times\frac{10}{8}=1\tfrac{1}{4} \text{ ins.}$$

To cut a triple thread of ⅜ in. pitch with a 4-thread lead screw; gears increasing by 4 from 24.

$$\text{Lead}=\frac{3}{8} \text{ in.}\times 3=\frac{9}{8}=1\tfrac{1}{8} \text{ ins.}$$

Turns per inch

$$=\frac{1}{1\frac{1}{8}}=1\times\frac{8}{9}=\frac{8}{9}$$

$$\text{Ratio}=4:\frac{8}{9}$$

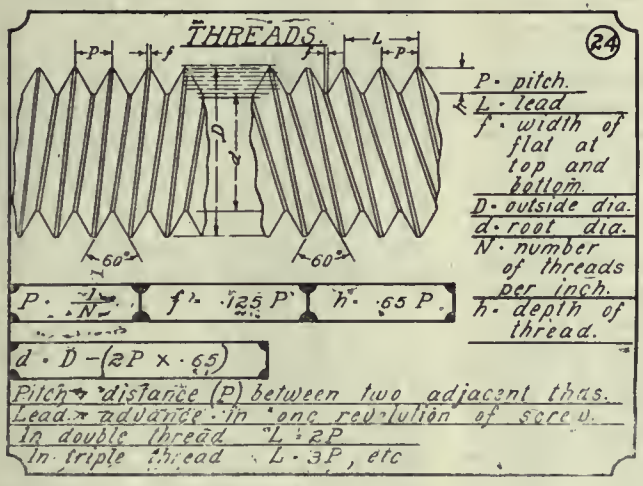
Multiplying by a number (27) for wheels required, we get 108 and 24.

Proof.—By formula (Chart 22).

$$T=\frac{L\times D}{A}=\frac{4\times 24}{108}=\frac{8}{9}$$

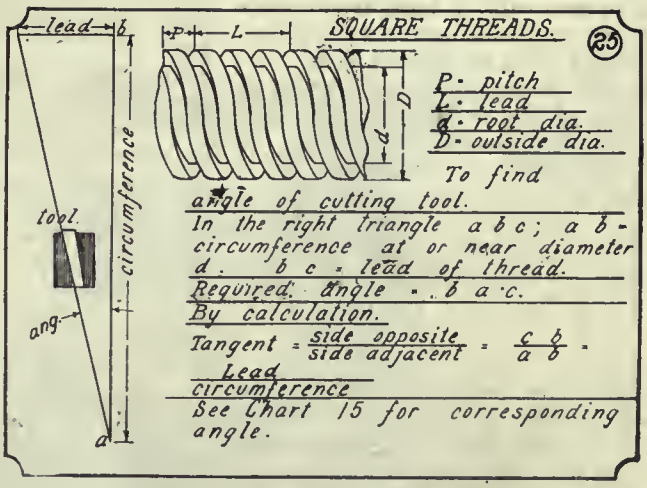
$$\text{Lead}=\frac{8}{9}=1\times\frac{9}{8}=1\tfrac{1}{8} \text{ ins.}$$

It occasionally happens that a thread is required having an odd pitch. In such a case the method of solution may require changing.



THREADS.
24
P. pitch.
L. lead
f. width of flat at top and bottom.
D. outside dia.
d. root dia.
N. number of threads per inch.
h. depth of thread.
60°
P = 1/N
f = .125 P
h = .65 P
d = D − (2P × .65)
Pitch = distance (P) between two adjacent thds.
Lead = advance in one revolution of screw.
In double thread L = 2P
In triple thread L = 3P, etc

ARITHMETIC CHART 24.



ARITHMETIC CHART 25.

To cut a single thread of 5-16 in. pitch with a 4-thread lead screw; gears increasing by 5 from 20.

5-16 inch pitch equals 16 threads in 5 inches.

Lead screw pitch equal 20 threads in 5 inches.

Ratio = 20: 16 = 5: 4.

Multiplying by 10 we have 50 and 40 for required gears.

$$\text{Proof—T} = \frac{L \times D}{A} = \frac{4 \times 40}{50} = \frac{16}{5} = 3\frac{1}{5}$$

$$\text{Or pitch} = \frac{1}{3\,1\text{-}5} = 1 \times \frac{1}{16} = \frac{1}{16} \text{ ins.}$$

It will be noticed that the pitch is always the reciprocal of the threads per inch, and vice-versa.

Sometimes, odd jobs appear, though not screw cutting, which require a selection of a train of gears for their solution.

To find the gears to chase a spiral having 6 turns in 9¾ inches; 4-thread lead screw, and gears increasing by 4 from 24.

$$\text{Turns per inch} = \frac{6}{9\frac{3}{4}} = 6 \times \frac{4}{39} = \frac{8}{13}$$

$$\text{Ratio} = \frac{8}{13} : 4$$

Multiplying each term by 13 for an even ratio, we have 52: 8, and again multiplying by 3 we get 156: 24.

Having no gear of 156 teeth, we must use a compound train.

Dividing 156 by 2 gives 78, but as we have no gear with 78 teeth, try dividing by 3.

156 ÷ 3 = 52 for gear on stud.

Now the intermediate pair must be in the ratio of 3:1, or 84:28.

Proof.—By formula (Chart 23).

$$T = \frac{B \times D \times L}{A \times C} = \frac{28 \times 24 \times 4}{52 \times 84} = \frac{8}{13}$$

$$\text{Pitch} = \frac{\frac{1}{8}}{\frac{1}{13}} = \frac{1}{8} \times \frac{13}{1} = 1\frac{5}{8} \text{ inches.}$$

When cutting threads especially square threads of excessive pitch or lead, considerable clearance is necessary on the tool to avoid interference. To find the required angle graphically. Form a right triangle of which the short side is the lead of the screw and the other side the circumference of the work taken at or near the root diameter of the thread. Then the angle formed at A (chart 25) will be the required angle. By calculation:—

$$\text{Tangent} = \frac{\text{side opposite}}{\text{side adjacent}} = \frac{\text{lead}}{\text{circumference}}$$

Example:—To find angle when a triple square thread of ½ inch pitch is required on a 2 in. bolt, depth of thread ¼ inch.

$$\text{Tangent} = \frac{\text{S.O.}}{\text{S.A.}} = \frac{\text{lead}}{\text{circumference}}$$

$$= \frac{1.5}{1.5 \times 3.1416} = \frac{1}{3.1416} = .3183$$

Looking in chart 15 for corresponding angle we find 17 degs. 40 ft. nearly.

What will be the bore for a nut to fit a U.S. standard 3-inch bolt, 3½ threads per inch?

By formula, chart 24.

$$d = D - (2P \times .65) = 3 - \left(2 \times \frac{1}{3.5} \times .65\right) =$$

3—.371=2.629 inches diameter.

RIVETING EFFECTS.

In a paper prepared for the summer meeting of the German Naval Architects, Professor R. Baumann, of the Technical College, Stuttgart, directed attention to the importance, first, of the power applied in the forming of the rivet head and of the pressure with which the latter bore on the plates after it was formed; secondly, of the pressure of the hot soft rivet on the sides of the rivet hole; and, thirdly, of the heating experienced by the plates connected. He sounded a warning against the application of excessive pressure by means of hydraulic riveters. The plates were thereby bruised and bent, and the holes were subjected to strong radial pressure, and it was no wonder that cracks showed themselves in cases in which the material was also not of the best.

The effects of the application of excessive pressures were illustrated in the paper by a series of sketches. The importance of allowing rivets to cool down, and the advantages that might accrue from a cooling of the riveting dies were pointed out. The plate round about the rivets was found to be heated in the process of closing to a temperature of 350 degs. C., or more at a distance of 5 mm. (about 2 in.) from the edges of the holes. Strains thus set up between the hot and the cold parts of the plate were, it was shown, most intense at the weakest points—i.e., at the edges of the plates opposite the rivets. Strain figures could be observed on the plates when the latter were polished showing that the yield point had been passed.

To enable a distinction to be made between the respective effects of pressure and heat, the laboratory had pieces of riveting done with cold lead rivets, and then had the latter replaced by hot iron ones put in with the same pressure. In order to produce the flow figures on the plates, much higher pressures had to be applied in the case of the cold than in that of the hot rivets. The formation of the figures began at the points of contact of the plates. With the hot rivets, figures appeared at 15,000 kilos. (nearly 15 tons), or rather more than a quarter of the power available, although the rivet heads were not yet properly developed.

The temperatures attained in riveting were often of degrees corresponding with yellow or blue heats, which were usually accompanied by brittleness. As a result of such conditions, cracks might develop later. An examination of a boiler plate in which some of the rivet holes had developed radial cracks showed that the insides of the holes had deep rough fissures probably due to rimering. The material would subsequently have been heated to yellow or blue heats, and the combinations of tension— rimering and heat straining—had sufficed to cause the cracks. Other holes that did not show signs of rimering had escaped without cracks. The punching of rivet holes would on the application of these principles also appear in a new light.

GILDING DIE CASTINGS.

In gilding die castings the articles must be previously coated with brass or copper and have a bright lustre. The following formula will give excellent results:

Phosphate of soda..... 8 ounces.
Sulphate of soda..... 1½ ounce.
Cyanide of sodium.....6 pennyweights.
Chloride of gold.....6 pennyweights.
Water .... 1 gallon.

To prepare the solution, dissolve the cyanide and chloride of gold in part of the hot water and the sodium salts in the balance; then mix together thoroughly. Anodes of gold, platinum or carbon may be used, and the bath should be kept at a temperature of 180 degrees F. at 2 volts pressure. If the articles are previously coated in the copper bath they should afterward be flashed in the brass bath to save an excess of gold.

The usual lacquers should be applied to brass, copper, silver or gold finishes. In plating die castings or articles of zinc, it is a distinct advantage to use as little free cyanide as possible. If this be reduced to a minimum, very little difficulty will be experienced in the blistering of the deposit. In nickel-plating, the baths should be maintained at the neutral point, as previously mentioned.

Contracts Placed. — The Board of Control of the City of Toronto, have recently placed the following contracts; Culvert pipe at $370 per foot, to the Canada Ingot Co., Guelph; electrical equipment, to the Canada Westinghouse Co., Hamilton; crushed limestone at $1.25 per ton to G. W. Essery, Toronto.

PROGRESS IN NEW EQUIPMENT

A Record of New and Improved Machinery and Accessories for the Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

GATE VALVES FOR N.Y. EDISON COMPANY.

PERHAPS the largest steel gate valves for superheated steam yet installed in any of the immense power plants of the American metropolis are those recently built by the Nelson Valve Co., of Philadelphia, for the New York

GATE VALVES FOR N. Y. EDISON CO.

Edison Co., New York City. That these valves are strictly in keeping with the proportions of this, one of the largest public service plants in the world is best shown by the photograph in which an ordinary man appears but a dwarf when compared to the valves beside him. Seven of these valves of the two types shown were built and shipped by the Nelson Valve Co. in fifty days from the receipt of the order, a remarkable record when it is considered that new patterns had to be made throughout.

Each valve, from top of stem, when valve is open, to bottom of body, stands 9 feet 1 inch in height, and the two types weigh 3,600 and 3,900 lbs. respectively. The valve shown at the left of the photograph is hand operated, though made with a large bushing just below the hand wheel, which may be removed for attachment of spur gears, if desired. The left hand valve is fitted with spur gears, bevel gears and chain for chain operation. The New York Edison Co. will install this valve on a vertical pipe line and run the extension stem, (to which is attached a bevel gear) through a wall for operating from another room. This valve can also be operated by chain, the chain wheel being attached directly to the valve stem. These valves will be used by the New York Edison Co., on header lines, 200 lbs., pressure and 150 degrees superheat.

Regarding the details of construction, the Nelson Co. say: — The valves have steel body and bonnets, with seat and disk wings of forged Monel metal and stem of rolled Monel. Guides in both bonnets and body are machined, also wing lugs on the gate disks. Bracks are provided on the inside of the yoke to support the gland when repacking the stem, while eye bolts at the top of the bonnet, swing out of the way so that the valve may be repacked.

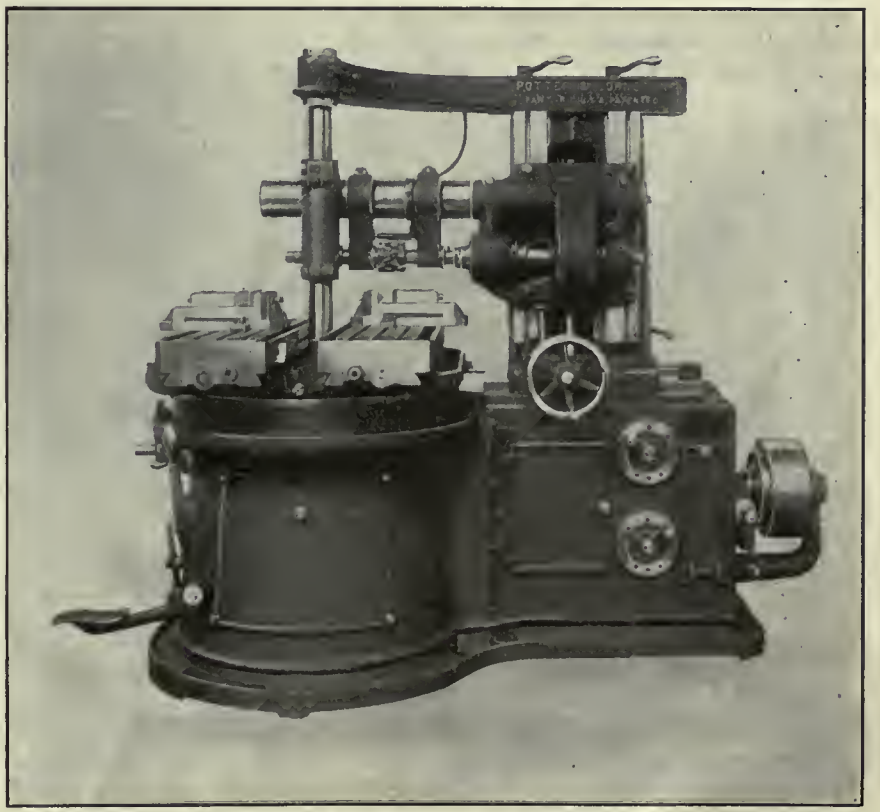
Both the steel and Monel metal used in these valves have a tensile strength of over 65,000 pounds per square inch, and the coefficients of expansion of the two metals is practically the same. This last point is an important one, since with the great changes in temperature where superheated steam is used, the expansion and contractions will cause a loosening of the seat rings, and other parts were this point not taken into consideration and provided for.

TURRET PRINCIPLE MILLER.

The description and accompanying illustration refer to a new machine being put on the market by the Potter & Johnston Co., Pawtucket, R.I., which is intended for the production of duplicate parts, and may be designated a semi-automatic manufacturing miller of the station type having a cutting and a loading position in use at the same time. It is semi-automatic, the operator only having to put work into the vise or fixture, and trip the indexing mechanism that shifts the position of the work tables. All other movements are automatic.

The work tables are located at a fixed height and parallel, and are carried on a circular saddle or turntable, which in turn is carried on a rigid base extending to the floor plate. The rotation or indexing of this turntable is the operation to which the turret principle is applied. The lost time between cuts is the time required for one index, plus a small amount of additional time, which may be necessary to clear the fixture from the cutters, as in straddle milling. The time for the overrun is reduced by providing a rapid traverse for this purpose. The rotating of the turntable is only in one direction so the finished work does not pass under the cutters after the cut is finished.

The spindle is fixed in a vertically adjustable slide which in turn is carried by a horizontally adjustable column. These adjustments are necessary for the reason that there is no knee or saddle or part to take their places. The overhanging arm and rigid arbor support are a feature of



TURRET PRINCIPLE MILLER.

the machine, and these are adapted to meet the conditions of the adjustments of the spindle slide and column.

When completing the machine the need for a strong, rigid, easily operated and compact miller vise was felt. This resulted in the design and construction of that shown in the cut. This is flanged, provided with jaws of hardened steel, and has a capacity of 6 in. wide, 1⅝ in. deep, and an opening 3½ in. long. The feature is the inserting of the wrench through the top instead of at the end. This wrench can be conveniently operated with a second bevel pinion integral with the nut on the vise screw. The construction is exceptionally compact.

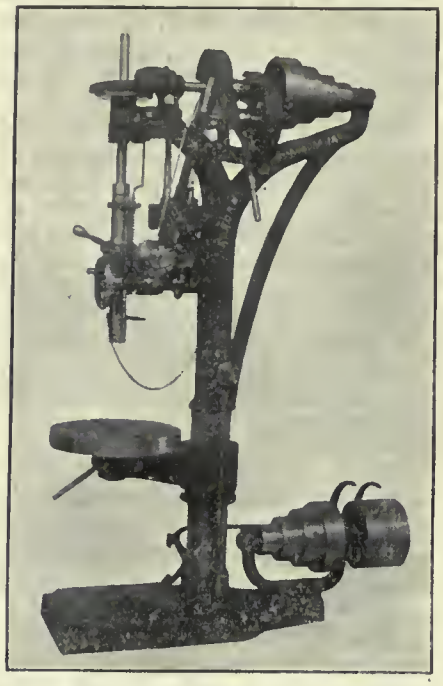
The machine complete with countershaft weighs about 7,000 pounds, and a 5-h.p. motor is recommended for the individual drive.

20-INCH STATIONARY HEAD DRILL.

The cuts represent the new 20-in. Aurora drills which have recently been re-designed and which embody some notable features. They are unusually heavy and rigid. The column and base are well ribbed, while the head is fitted on column with tongue and groove and securely bolted with three ½-in. cap screws. The bevel gears are of 3 to 1 ratio, the spindle gear being 7½ in. in diameter and made of a special semi-steel. The cone pulleys are from 4½ in. to 9¼ in. in diameter, and carry a 2½-in belt. The tight and loose pulleys of 9 in. in diameter carry a 3-in. belt and run at 550 to 600 r.p.m. The table rests on a large flat bearing besides the usual pivot bearing, thus insuring perfect alignment even when drilling on the edge of the table. The spindle is fitted with ball thrust bearing and has 8-in. travel.

PLAIN WHEEL AND LEVER DRILL.

On the plain wheel and lever drill, the worm is engaged and disengaged by means of an eccentric bush. The feed lever is operated by ratchet and pawl, which automatically disengages when in vertical position. On the power feed drill the feed gears are of hardened steel, mounted directly on the head in an oil-tight case, and three feeds can be obtained instantly without stopping the machine. Each feed is marked in view of the operator. The spindle sleeve is graduated and equipped with automatic stop collar, which disengages feed at any desired depth. Table and base are furnished with T slots. The plain wheel and lever feed drill weighs 735 lbs., and the drill complete with back gear, geared power feed and automatic stop weighs 900 lbs.



POWER FEED AUTOMATIC STOP DRILL.

The Aurora Tool Works Co., Aurora, Ind., are the manufacturers of the foregoing products.

THE QUICTITE AUTOMATIC DRILL CHUCKS.

A VERY neat automatic drilling machine chuck has been recently put on the market by the Automatic Drill Chuck Corporation of Detroit, Mich. It is the result of the increasing demand for quick change drill chucks created by the popular systems of interchangeable manufacturing.

The device consists essentially of three sets of eccentric cams geared to an outside knurled shell or cover so that rotating the shell increases or decreases the space between the cams or jaws. The simple gripping of the casing by the fingers when it is in motion serves to turn it backwards and release the drill, the jaws being returned to the closed position by means of a flat coiled spring.

The chuck is applicable to straight shank drills, counter bores and reamers within its capacity and operates at speeds as high as 4,000 r.p.m. The jaws tighten as the torsion on the drill increases and the grip is by means of curved surfaces of fairly large radius rather than sharp edges.

Quietite chucks are made in three sizes for use with drills, No. 40 to ⅜ in., 3-16 in. to ½ in., and ½ in. to 1 in., and are furnished with the regular Morse taper shanks or without as desired. The whole presents a neat and attractive appearance with no projecting points and should commend itself from a safety point of view.

WIRE DRAWING MACHINE.

A wire-drawing machine of compact yet heavy and rigid design and furnished either direct connected to motor, in series or belted, as shown in Fig 1, is a recent product of the Standard Machinery Co., Auburn, R.I.

This machine is driven, as can be seen in Fig. 1, by a friction clutch. The driving shaft is back geared to the large spur gear which sets directly under the table, and on the shaft with this spur gear is a bevel pinion which in turn meshes with the vertical spindle of the drum. The machine is started in motion by throwing in the clutch with the

QUIETITE AUTOMATIC DRILL CHUCK.

shipper handle shown on the extreme left. The handle on the extreme right is for the purpose of throwing the internal clutch and setting the draw-out drum in motion.

The wiring starting attachment seen in Fig. 2, then starts pulling wire through the die, and when it revolves as far as the back of the machine, the hand lever on the starting tongs is hit by the knock-out which automatically opens the tongs, and throws the main drawing drum into operation. The wire thus started, amounting to one-half of the periphery of the drawn out drum, is clamped in the jaws on the top of the main drum, and the machine draws this continuously through the dies which are supported in the knee shown in the table of the machine. The wire yokes shown going from the inside of the main drum are for the purpose of preventing the wire from going any higher and also serve as guides for the baling of the wire.

The front and back of the machine are fitted with sheet metal panels which can be easily removed when repairs or overhauling become necessary.

The diameter of the drum is 22 ins.; the height, 8½ ins.; linear speed, 50 feet per minute; linear speed of draw-out drum, 19 ft. per minute; diameter of clutch pulley, 24 ins.; face of clutch pulleys, 8 ins.; speed of clutch pulley 92 r. p.m.; height of machine, 5 feet; width, 4 ft. 6 in.; length including clutch and outboard bearing 7 ft., 6 in.; weight of machine, 4,000 pounds. The particular model shown is suitable for drums of 22 ins. to 30 ins., inclusive.

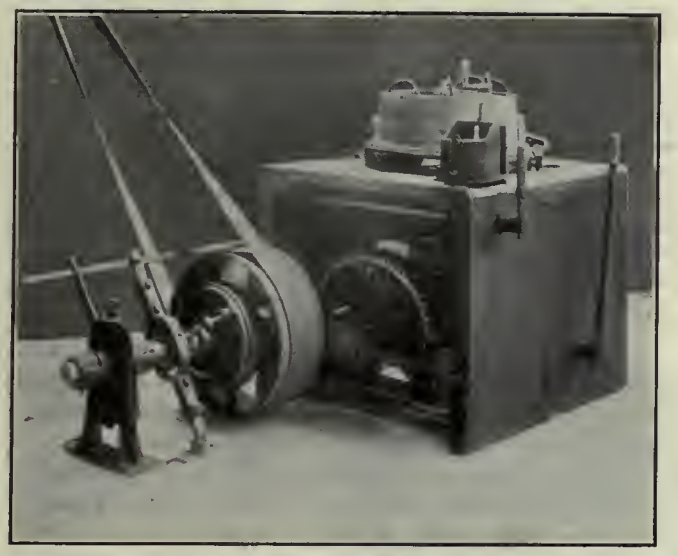


FIG. 1. WIRE-DRAWING MACHINE.

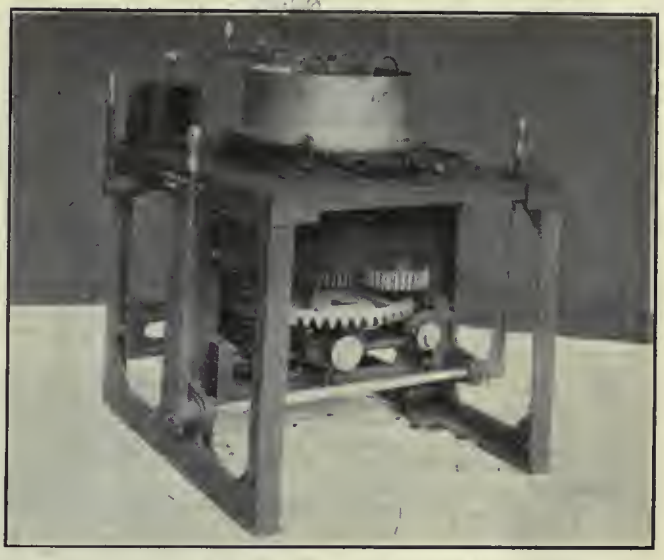

FIG. 2. WIRE-DRAWING MACHINE.

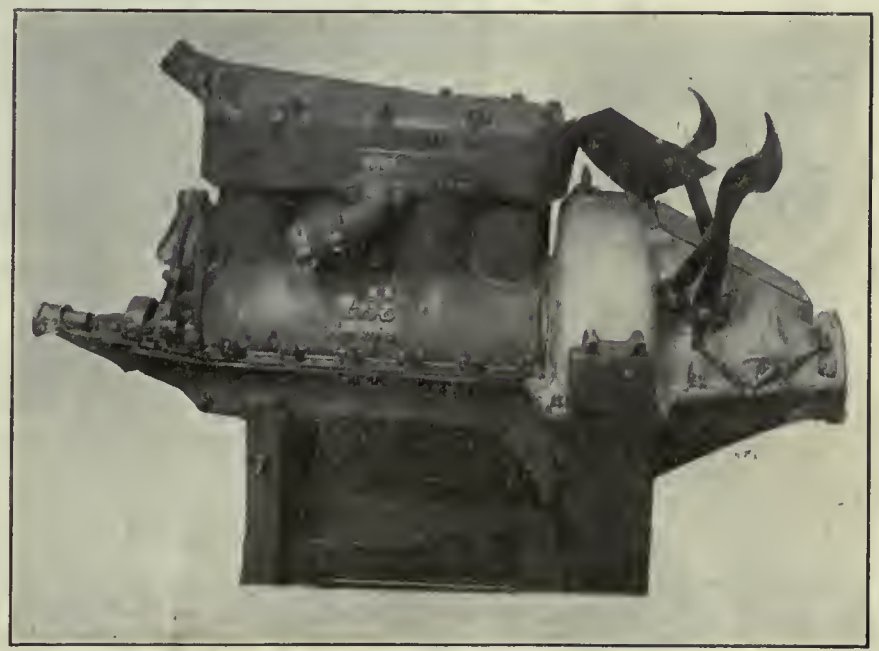
FORD COMPANY NEW ASSEMBLING PLANT AT LONDON, ONT.

The growth and expansion of the Ford Motor Co. of Canada, Ltd., is illustrated by the new branches the Company is constantly building, as well as by the ever-increasing number of cars seen on city streets and country roads. At the present time the Ford Company is adding three big branch assembling factories in the Dominion. Announcement has already been made that in Toronto a Ford branch factory is under process of construction; and at Montreal the site of the building is being excavated. Now comes word that at London property has been purchased and plans are being prepared for a similar assembling plant of the most modern construction and equipment.

The Ford Motor Co. of Canada is following in this manner the same policy pursued by the parent organization at Detroit. That is, it has always been the plan of the Ford management to aid its distribution machinery by the erection and maintenance of company branches at strategic points throughout the world. This is one of the secrets of huge production and the economy of manufacture that characterize the Ford, for these branches are more than sales rooms and distributing centers under company management. They are also complete assembling plants by the aid of which cost of transportation is reduced and promptness of delivery is secured.

The J. B. Turney & Co., Ltd., of Lethbridge, Alta., has been awarded the contract by the Cranbrook city council for the supply of Mannesman seamless steel water pipe. The contract is for over 5,000 tons at a cost of approximately $43,000.



THIS MOTOR WAS BUILT ON APRIL 24, 1914, AND MARKED THE ACHIEVEMENT OF THE HALF-MILLION MARK IN PRODUCTION BY THE FORD MOTOR CO.

CANADIAN MACHINERY, VOL. XII.

VOLUME XII of Canadian Machinery starts with the present issue, and we think it opportune to direct the attention of our subscribers and advertisers not only to the scope of our publication but to the effort being made as evidenced by the practical value of the different departments, to maintain it as the premier, most effective and reliable medium in its field here in Canada.

Canadian Machinery in its editorial and advertising columns seeks to set forth the development of the machine tool and directly kindred industries not only within the confines of the Dominion of Canada but of the leading countries of the world in these particular spheres, providing thereby opportunity for the enterprise of these latter, and incentive and direction to our own manufacturers and mechanics in order that they too may design and build to the highest purpose, and in the nature of things so improve on example and precept that in the matter of achievement, all may correspondingly be benefited.

From fifteen to twenty pages in each issue, which by the way is weekly, are devoted to articles bearing on machine shop practice and equipment, this broad phrase embracing general articles on lighting, sanitation, employees' welfare, plant layouts, materials and processes of manufacture, methods and devices, systems of remunerating workmen, efficiency applications, systems of timekeeping, storekeeping and accounting, instruction courses, an editor's correspondence department for the discussion of live industrial topics, a question and answer series dealing with the arithmetical and consequently more rapid, systematic and correct determination of equipment size, disposition and application to the efficient and economical performance of not only the more common tasks but those presenting more or less hitherto unusual features, etc.

Our industrial news department, to which some half dozen pages in each issue are devoted, contains a complete and current record of business opportunities, and the privileges of having these available in snappy, compact reference form is so highly appreciated, being closely followed by manufacturers, agents and dealers, that a pardonable pride in having prominently featured a **Business Opportunity** section is naturally felt by us. There is no such phrase in our organization as **standing still**, and though for the time being industry's wheels are rolling lazily, and the scope of manufacturing enterprise is curtailed, our plans are being matured to still further enhance to our clientele the value of, to them, our indispensable **Industrial News Department.**

Market quotations on raw and finished materials entering into the various products of machinery manufacturing plants, together with weekly market letters from correspondents in touch with the pulse of business in leading industrial centers across Canada show at a glance the price of a required commodity and indicate to the shrewd buyer the influences that may be at work or that are likely to early develop, with the relative price trend.

Practically every machine and railroad shop, iron and steel mill, iron and steel foundry, steam, marine, hydraulic and electrical engineering establishment is represented on our subscription list in their capacity as such and in the persons of their employees, the foreman of every department of many of them included. Advertisers have therefore the opportunity to influence sales of machinery and equipment through the administration and operating departments with an effectiveness not otherwise possible.

Ten years of conscientious work and service have given Canadian Machinery a prestige unapproached by any class medium in Canada, and in the birth of a new volume there is abundant evidence that this will not only be maintained, but still further enhanced by the editorial service to be rendered in the various sections of machinery developments, progress and activities.

We have just crossed the threshold of a new year of experience for a United Canada, and there is no gainsaying that its close will register a further advance in the direction of added commercial and industrial achievement. That Canadian Machinery will not only contribute but actively direct such a consummation is both desirable and conclusive.

INDUSTRIAL NOTABILITIES--No. 41

JAMES WHALEN, the subject of this brief sketch, was born at Collingwood, Ont., April 29, 1869, the son of Joseph W. and Alice Broad Whalen.

He accompanied his parents to Port Arthur, Ont., in 1873, receiving his education in the public schools of that city, and thereafter entering the logging business. Following considerable experience gained and success achieved in this, he entered the field of railroad contracting.

Mr. Whalen has taken an active part in the commercial development of Port Arthur, in both its city and port feature; as a result we find him occupying the following among other positions in prominent marine and industrial enterprises, a majority of

JAMES WHALEN,
President, Western Drydock & Shipbuilding Co., Port Arthur, Ont.

which he organized: President Western Dry Dock & Shipbuilding Co., Port Arthur, Ont.; president and general manager Great Lakes Dredging Co.; president and general manager Canadian Towing & Wrecking Co.; vice-president and general manager Thunder Bay Contracting Co.; president General Realty Corporation; president Canada Pebble Co.; director Thunder Bay Harbor Improvement Co., etc.

He married Miss Laurel Conmee, daughter of James Conmee, M.P. in 1896, and has two sons and three daughters. He is a Roman Catholic in religion, a member of the Knights of Columbus, and resides at 120 Court Street North, Port Arthur, Ont.

The General Market Conditions and Tendencies

This section sets forth the views and observations of men qualified to judge the outlook and with whom we are in close touch through provincial correspondents.

Montreal, Que., June 29, — Business is still reported to be on the quiet side, though a number of contracts are said to be pending which would help considerably to liven up the situation if they could be closed. Most of the supply houses state that there is a general dullness prevailing and that there seems little likelihood of much improvement until the fall. Local building operations are considered quite satisfactory, in view of the general tendency to proceed with caution. In addition to several bank and office buildings, and two projected theaters, the Harbor Commissions are erecting new freight sheds, the Dominion Government is completing the new Customs building, and an unusual amount of residential building is also being carried on.

It was announced last week that the Canadian Northern Railway would erect a temporary terminal on Lagauchetiere Street, at the entrance to the Mount Royal Tunnel, in order to take care of traffic there next year. It is expected to have the tunnel completed and in operation by May, 1915, and the projected million-dollar terminals could not be finished inside of two years. The temporary building will be utilized later for express and freight purposes.

The Board of Control of Montreal has decided to buy a steam pump of 24,000,000 gallons capacity instead of two 12,000,000-gallon pumps, for which tenders have already been received. New tenders will be called for. The new pump will increase the daily water consumption capacity to 102,000,000 gallons.

The Shawinigan Technical Schools, at Shawinigan Falls, Que., are nearing completion and orders were placed last week for the installation of machinery and supplies with the Canadian Fairbanks-Morse Co.

Metals.

Metal markets still remain quiet and buying is of a hand-to-mouth nature. There seems to be a disposition on the part of many to buy only sufficient for immediate needs, under the impression that prices will not go higher for some time. A scarcity of pig lead is reported and a slight advance in price resulted this week. Sterling quotations are: Tin, spot £137, future £138 12s 6d; copper, spot £60 1s 3d, future £60 13s 9d; lead, £19 7s 6d; spelter, £21 5s; pig iron, £51 1s.

Toronto, Ont., June 30. — There is no perceptible change in business conditions this week. The external political situation has not improved and is having a depressing effect on the money market, and therefore on trade. Taken on the average, we should estimate that plants are running at not more than 60 per cent. capacity, but the view seems to be generally held that the turn has been made and that conditions will from this on improve. The recovery, however, will be slow, although none the less sure. There is no doubt that business is very quiet, although we hear occasionally of a revival in a specific industry. In spite of this being sometimes of a temporary character, it serves to show that conditions are not really as bad as some would suggest.

Firms most seriously affected by the depression are makers of agricultural implements, automobiles and builders' supplies. The buying season for implements and automobiles is practically over, which may account to some extent for this condition. Manufacturers will not risk laying in large stocks for next season unless the outlook improves considerably, and until there is an assured demand for their products. The building trade is quiet, and it is doubtful whether it will show much improvement this year.

Dealers throughout the country have allowed stocks to get low and sooner or later the demand must revive, and substantial orders will result when trade does pick up. On account of poor trade, manufacturers have been retrenching and curtailing expenses of all kinds as much as possible. As money becomes

more plentiful and the requirements of the community accumulate, there will be created a condition which will hasten a return to greater business activity. In the meantime, manufacturers must continue to exercise rigid economy and keep a watchful eye on developments.

Steel Market.

Business in the iron and steel market shows no change, being still very quiet. The railroads, except in one isolated case reported last week, have not come into the market. The Grand Trunk Railway recently raised $10,000,000 to finance the G.T.P., and the effect of this should be seen at an early date. The reorganization of the Canada Iron Corporation is being proceeded with and it is expected that a report will be presented to the bondholders at a meeting to be held on July 2nd. The demand for structural steel is light on account of the continued dullness in the building trade. In the United States the buying of steel products this month has not come up to expectations, although the tonnage showed a considerable increase over May. Prices have been maintained except in some cases where the mills are showing a tendency to grant concessions to consumers.

Pig Iron.

The pig iron market is very quiet, little business being done. Consumers are still continuing to keep stocks as low as possible. We understand that the International Harvester Co. and the Oliver Plow Co., both of Hamilton, have recently laid off a number of hands. Both these concerns are large users of pig iron.

Machine Tools.

Dealers in machine tools have become resigned to the situation, and what would be a small order in good times assumes quite important dimensions these days. There is consolation in the fact that industries must expand and the requirements for tools will accordingly increase.

Metal Market.

Business in metals shows no change of any description, the market being quiet and demand light. Prices are steady, with the exception of tin, which has weakened, being quoted at $33.

Ottawa, Ont., June 29. — Canadian manufacturers, especially of machinery and agricultural implements, will be interested in the information which has been received from Australia that the Commonwealth is contemplating a complete revision of the tariff. An interstate commerce commission has been making a thorough investigation. Victoria, Tasmania and New South Wales have already been visited and subsequently sittings will be held in Queensland, Western Australia and South Australia. It is expected the Commission will complete its work about the end of the year.

The report received at Ottawa says:

"To facilitate investigation, special confidential forms are set out enumerating a comprehensive series of questions which must be completed by applicants soliciting amendments of the existing tariff—either for increases or decreases—and accompanied by a statutory declaration.

"Established industries must set out in detail particulars respecting the capital, value of plant, raw materials, and the number of and wages paid to employees. Prospective industries are required to submit estimates in relation to the capital, plant and employees, etc., to be engaged, should sufficient protection be granted by Parliament. In both instances, information is desired respecting imported goods of similar character, the rate of wages paid by oversea manufacturers, and evidence is solicited in regard to the articles being exported to Australia at less than the fair market value at which they may be sold in the country of production (otherwise 'dumping')."

The applications so far received are as follows:—

For increased duties or retention of duties	205
For reduction of duties or against duties	220
Miscellaneous	44
Total	469

In view of the bill which was introduced to form a tariff commission in the Canadian Parliament but which was killed by the Senate, the organization of the Australian Commission is interesting. Its scope is very wide and it seems to fulfill the duties of the Canadian Railway Board as well as that of a tariff commission. In addition to its powers in regard to railway rates, the commission is charged with the duty of investigating all matters which in the opinion of the Commission ought in the public interest to be investigated affecting:

(a)—The production of and trade in commodities;

(b)—The encouragement, improvement and extensions of Australian industries and manufactures;

(c)—Markets outside Australia, and the opening up of external trade generally;

(d)—The effect and operation of any tariff Act or other legislation of the Commonwealth in regard to revenue, Australian manufactures, and industry and trade generally;

(e)—Price of commodities;

(f)—Profits of trade and manufacture;

(g)—Wages and social and industrial conditions;

(h)—Labor, employment, and unemployment;

(i)—Bounties paid by foreign countries to encourage shipping or export trade;

(j)—Population;

(k)—Immigration, and

(l)—Other matters referred to the Commission by either House of the Parliament, by resolution, for investigation.

Personal

Geo. E. Turner, building commissioner at Edmonton, Alta., since 1909, has resigned.

W. H Young, manager of the Winnipeg office of the A. R. Williams Machinery Co., is in Toronto on business.

Henry Bertram, president of the John Bertram, Sons & Co., Dundas, Ont., recently visited Fort William, Ont.

Leonard L. Merrifield, consulting engineer to the Consumers Gas Co., Toronto, died suddenly on June 21, aged 58.

George Bradshaw, G.T.P. safety engineer, is now in Winnipeg installing the "safety first" principles among the officers and employees of the system.

A. R. Wooldridge, who is in charge of the scale sales department, Canadian Fairbanks-Morse Co., Toronto, has left on a visit to El Paso, Texas, where he will be married.

L. D. Gillett, boiler inspector of the Dominion Board of Railway Commissioners, is at his home in St. Thomas, Ont., suffering from an injury which he received to his foot while in Windsor a few days ago.

W. H. Rosevear, secretary the Western Canada Railway Club, Winnipeg, has resigned, and until the annual elections in September, Louis Kon, Immigration Agent, G.T.P. Ry., Winnipeg, will assume the duties.

Herbert M. Ewan, assistant sales manager of the Canadian Steel Foundries, Ltd., Montreal, Que., has been appointed general sales manager of the company, and also of the Canada Car & Foundry Co., and Pratt & Letchworth, Brantford, Ont.

T. C. Burpee, C.E., president of Concrete Builders, left Fredericton, N.B., on June 23, for Montreal, Toronto and other Canadian cities for the purpose of visiting the best and newest concrete plants with a view to securing new machinery. Mr. Burpee proposes buying the latest brick-making machinery on the market.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News.

Engineering

Milton, Ont.—The town will guarantee the bonds of the Imperial Foundry Co., to the amount of $7,000.

Calgary, Alta.—It is reported that an eastern corporation will locate a steel plant in Calgary in the near future.

Nelson, B.C.—The town will buy a number of gas meters, piping and fixtures. H. P. Thomas is superintendent of the gas plant.

Okotoks, Alta. — The International Supply Co., of Medicine Hat, will establish a machine shop here for repairing oil well drilling outfits.

Yorkton, Sask.—Plans are being prepared for a cooling system at the new power house, which will be under the supervision of the town engineer.

Stratford, Ont.—The Water Commission is securing information on the advisability of replacing the present steam auxiliary plant at the pumping station with a gasoline driven pump.

Toronto, Ont—The Board of Control approved of a recommendation of Commissioner Harris for an addition to the main pumping station at a cost of $97,000.

Harriston, Ont. — Fire on June 25, broke out in a warehouse belonging to the Harriston Stove Works. The loss is estimated at $1,000, which is fully covered by insurance.

Medicine Hat, Alta.—The building being erected by the Carey Wright Radiator Co. on the south industrial site was seriously damaged by a wind storm recently.

Toronto, Ont—A provincial license was issued on June 5, to the National Tube Co., incorporated by Dominion charter on January 10, 1912, to carry out all the provisions of its charter in the Province of Ontario.

Regina, Sask.—The first carload of bunkers and coal handling machinery for the new power house has arrived, and the work of installing this is now in hand. Other consignments are expected to follow immediately.

Toronto, Ont.—The National Iron Works obtained a permit recently for the erection of a $50,000 pipe foundry to be located at the foot of Cherry street. It will be one storey in height and built of brick, steel, cement and gypsum.

New Toronto, Ont. — Tenders have been asked for the pumps, building of pump-house and filters, and laying of intake pipe, and it is expected that contracts will be let shortly.

Esquimalt, B.C.—The Dominion Government will call for tenders in a few days for the new public drydock which is to be built at Esquimalt, B.C., at a cost of about $3,000,000. It will be 1,100 feet in length and similar in design to the dock under construction at Quebec.

Galt, Ont.—A new industry for this town is the Galt Ornamental Iron Co., of which John Spalding, jr., for 12 years superintendent of the Otis-Fensom Elevator Company, of Hamilton, is president, and R. J. Spalding, a well-known commercial traveler, is secretary- treasurer.

WHAT OUR MANUFACTURERS SHOULD DO.

To hold and expand our foreign trade, our manufacturers must do their part. It is not wise for the Government to attempt to supplant private enterprise or to do that for the manufacturer which he should do for himself. The manufacturer must be up-to-date in his machinery and in his methods, and in the conduct of his business. He must turn out his best goods. He must do his part co-operatively with others through trade organizations. He must go after the foreign business as well as the domestic business. He must send his agents out into the field he would occupy. He must pack his goods properly. He must outdo his competitors.

Montreal, Que.—City Engineer Janin has recommended that a 24-million gallon pump be installed at the low-level pumping station instead of two 12-million gallon pumps, for which tenders were received two months ago. The Board of Control will consult the city attorneys regarding the cancellation of the former tenders.

Quebec, Que.—The large agricultural implement factory of Charles A. Julien, at Pont Rouge, was destroyed by fire on June 23. The loss, it is said, is over $100,000. The factory was one of the largest of its kind in the province, and employed many hands. Besides manufacturing implements, the plant furnished the power for lighting, etc., in the village of Pont Rouge, and this is now cut off.

Edmonds, B.C. — Another industry wants to locate in the Burnaby municipality. Seven acres of land is the amount asked by an iron and steel manufacturing concern for a site on the Fraser river. In a letter to the Board of Trade, the company stated that they would employ in the neighborhood of 200 men and would start work on the plant in the very near future. The matter was referred to the secretary with power to investigate.

Chatham, Ont.—A special meeting of the city council was held on June 29 for the purpose of considering a proposition whereby Chatham will secure a new industry. There is a concern in communication with the city for the purchase of the old Defiance Ironworks plant, and the deal will likely be closed. This plant has been on the city's hands for some time and the present proposition is only one of many made in recent years whereby the plant would be disposed of.

Electrical

Armstrong, B.C. — A by-law is contemplated for raising $5,000 for electric light extensions.

Grenfell, Sask.—The town proposes to make extensions to the electric light system. The sum of $6,500 will be required for the purpose.

Belleville, Ont.—It is reported that the Hydro-Electric Commission will take over the Seymour Power Co. and affiliated companies.

Lucan, Ont. — The Hydro-Electric money by-law was carried here last Friday by a record vote of 95 per cent. of

the available vote. Not one ballot was cast against it.

St. Catharines, Ont.—Hydro-Electric lighting was officially turned on in St. Catharines. last Saturday evening by Mayor Petrie in the presence of a number of city officials and citizens.

Simcoe, Ont—A by-law on June 26, carried by a vote of 399 to 11, to raise $40,000 for the purpose of installing a plant in connection with the hydro-electric for street, commercial and private lighting. The vote was heavy, considering the fact that no other by-laws were submitted.

Windsor, Ont. — The work on the Windsor-St. Thomas extension of the Ontario Hydro-Electric Commission's power line, has we understand progressed sufficiently to warrant power being available by the end of July. The engineers are now preparing to make the connection with the local distributing stations at Windsor and Walkerville.

General Industrial

Hamilton, Ont.—The McGregor Shirt Co. will build a factory here.

Edmonton, Alta—The Board of Education will purchase equipment for the new technical school at an estimated cost of $5,000.

Estevan, Sask.—A project is on foot backed by Regina financial men, that will assure for Estevan a large briquetting plant to make raw lignite into domestic fuel.

Oakville, Ont.—The by-law to exempt the Glassco preserving plant here from taxes and water rates for ten years, was carried by a majority of 137. This is the third industrial concern to locate here in a short time.

Sarnia, Ont.—C. L. Anker-Holt, of Port Huron, states that he expects to interest a number of Canadians in the establishment of a branch cream separator factory here. He is president of the Anker-Holt Co., of Port Huron, Mich.

Estevan, Sask.—A strong company is being formed for the purpose of manufacturing carbonized lignite for commercial purposes. The company, which consists largely of Winnipeg capitalists will build a large plant just east of here.

Regina, Sask.—Excavation work for the new Saskatchewan Co-operative Elevator Co. building, on the corner of Twelfth avenue and Smith street, was commenced recently. The building when completed, will be a two-storey structure and will cost in the neighborhood of $45,000.

New Westminster, B.C.—The Pacific Chocolate Co. plant was completely destroyed by fire on June 25. The total damage is estimated at $75,000. It was only through the exertions of the firemen that adjoining premises of the Borden storage warehouse and the Vulcan Ironworks were saved.

Redcliff, Alta.—A large deposit of silica sand has just been discovered near here. Under test it withstands a temperature of 3,000 degs., and possesses properties which indicate its suitability in clay products, iron works and rolling mills. The discovery has aroused considerable interest in Redcliff.

Vancouver, B.C.—Quite a number of offers of leases on very reasonable terms have been received by Industrial Commissioner Davison in answer to his advertisement for industrial sites. The communications which he had in hand indicate that the advantages of Vancouver are being well studied. The establishment of a cigarette factory before very long is practically assured.

Windsor, Ont.—With the finding of a supply of salt that will last 200 years, according to officials of the company, work will be started on the erection of the Canadian Alkali Co. plant at Sandwich, immediately. The company was granted tax exemption for ten years by the Sandwich ratepayers at the elections in January by a large majority. According to Manager Dodson, the plant will mean an expenditure of nearly $1,000,000 before it is completed.

St. Mary's, Ont.—It is reported that a second cement company proposed some weeks ago, is now a certainty and construction work will begin at once on a building designed to turn out about 1,200 barrels of cement a day, the capacity of the present plant. Local men as well as outside capital are involved. Mr. F. G. Sanderson is one of the leading local men in the deal. It is expected that the new plant will be in operation in time for next year's trade.

London, Ont.—In connection with the inducing of pottery and clay industries to locate here, Industrial Commissioner Phillips has had tests of clay found in this neighborhood made by the Department of Mines. The data, which has not been sent on as yet, will be furnished manufacturers with a view to inducing them to locate here. It is understood that the Department reports very favorably on the quality of the clay for manufacturing purposes.

Brantford, Ont.—The Ontario Concrete Post Co., will establish a plant here for making reinforced concrete posts for all purposes. The company has been capitalized at $40,000, and the following officers have been elected, with G. H. Cooper as manager: J. W. Clark, president; Col. J. Z. Frazer, vice-president; John O. Whiting, secretary-treasurer; Joseph R. Moyle, director; R. W. Devereaux, director; A. R. Rose, director; D. W. Henry, director.

Montreal, Que.—The Thompson & Morris Co., of Brooklyn, N.Y., which has numerous branches throughout the United States, and which manufacture corrugated paper board for packing purposes, have located on a property north of the Delorimier race track on the C.P.R. line and intend to erect a large factory for the manufacture of the above mentioned product. Vice-President Day and Manager Hays closed the deal regarding the site. The establishment of this plant is expected to involve an expenditure of over a million dollars.

Montreal. Que.—It is reported that the C. F. Massey Co., of Chicago, capitalized at $20.000.000, have closed a deal through Andrew Christ, junior, secretary, and T. H. Parker, general manager, locating a site for a branch plant to be known as the Canadian Concrete Products Co., to be situated on the line of the Canadian Pacific Railway behind the mountain on the Cote des Nieges road. The company intends to erect the building immediately. It has secured large contracts from the railways and other big corporations for concrete poles, battery wells and other products in which it deals.

Municipal

Fort William, Ont. — The Board of Works will buy a street flusher at a cost of $1,170.

St. Catharines, Ont. — A by-law is contemplated for raising $30,000 for extensions to the water works system.

North Bay, Ont.—A by-law will be voted on by the ratepayers on July 8, to authorize the purchase of fire-fighting apparatus to cost $5,000.

Windsor, Ont.—A by-law will be voted on by the ratepayers on July 3, to authorize the borrowing of $23,000 for the purpose of establishing an incinerator plant.

Weston, Ont.—The waterworks system may be improved by having another filter bed added. It is the idea of the commissioners that the new bed shall have a concrete bottom so shaped that it can be drained out.

Brantford, Ont.—By a vote of 763 to 550 property owners last Friday, car-

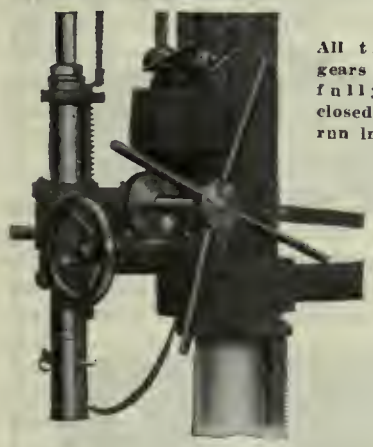
MACHINE TOOL DEPT.

The A. R. Williams Machinery Co., Ltd., 64-66 Front St. W., Toronto



All these gears are fully enclosed and run in oil.

Table removed from table arm, showing the large flat bearing on which the table arm rests.

Head of our drill on which is mounted the gear feed.

Important Features in the Aurora Drilling Machine

COLUMN is heavy and well ribbed.

HEAD AND TABLE ARM has long bearing on column.

TABLE rests on a large flat bearing besides the usual pivot bearing.

PULLEYS are large in diameter and carry a wide belt.

ALL LARGE GEARS are made of special semi-steel with high percentage of manganese and carbon, and pinions are of steel, making an excellent wearing combination.

SPINDLE BEVEL GEARS are of 3 to 1 ratio, which means a high speed for driving pulleys, giving plenty of power.

THE ALL-GEARED FEED is on the head and controlled directly at the hands of the operator. Each feed is indicated and can be changed while machine is running. Feed gears are of hardened steel and run in oil in a fully enclosed case.

AURORA DRILLS are built in 20″, 21″ and 25″ Stationary Head type; and 22″, 24″, 26″, 28″, 32″, 36″, 40″ and 44″ Sliding Head type.

The Aurora Tool Works Co.

Aurora, Indiana, U.S.A.

ried a by-law providing for the guaranteeing of the bonds of the Brantford Industrial Realty Co. up to 75 per cent. This is an organization formed to purchase factory sites and erect buildings thereon for factories.

Preston, Ont.—The fire and light committee of the town council has considered the recommendation made by the inspector of the Underwriters' Association to add more hydrants for protection in case of fire. The inspector asked for five hydrants, but the committee recommends to the council to have seven new hydrants installed at once.

Port Alberni, B.C.—The five money-loan by-laws voted on by the ratepayers on June 18 were carried. The by-laws were as follows:—Street improvements, electric light and power extensions, school building, bridge building, and municipal buildings. The total amount of debenture issue for the by-laws amounts to $41,000.

Edmonton, Alta.—City Commissioners opened the tenders for the new sewerage special plant on Ross Flats, which were submitted to the commissioner of public works. The following are the prices submitted: McPherson & Quigley, $40,260.30; Lowndes, Brow & Hangreaves, $28,471.62; J. Dunlop, Johnson Construction Co., $30,496.21; A. G. McGarry, $37,828.64; Holbert, Wilson & Southworth, $38,641.94; Midland Construction Co., $28,383.81; Ferenback & Co., $31,960; John K. Auld, $34,115; Manders & Gregory, $31,866.48; Hotson, Leader & Goode, $37,486.

Trade Gossip

The Schuchardt & Schutte Co., Toronto, are putting on the market the "S. & S" unbreakable parallel vise.

The Eastern Canada Car Co., New Glasgow, N.S., has received a substantial order for box cars from the Intercolonial Railway.

The E. J. Woodison Co., Detroit, Mich., have opened a branch at 378 Ellicott Square Building, Buffalo, N.Y., under the management of Mr. Pierce G. Smith.

Montreal, Que.—The Abitibi Pulp & Paper Co., will shortly increase their capital by $1,000,000 in order to finance the new extensions at Iroquois Falls, Ont.

Toronto, Ont.—A contract was awarded by the Board of Control to the Northern Crane Works, Ltd., Walkerville, for the supply of electric traveling hoists and Wagner motors of 12½ h.p., at a cost of $7,920.

The A. B. See Electric Elevator Co., Toronto, has been awarded the contract for elevator equipment in the new Methodist Book Room, Toronto.

The Northern Electric & Mfg. Co., Montreal, have been awarded a contract by the town of Outremont, Que., for 20,000 feet of wire cable at $93.50 per thousand feet.

Wilson, Townsend & Saunders Co. have been awarded a contract by the Toronto Board of Control for the erection of a reinforced concrete bridge near Bellwoods Park, at a price of $40,700.

The A. R. Williams Machinery Co., Toronto, have sold a Brown, Boggs Co. press to the Toledo Scale Co., Walkerville, Ont.; a Baush boring mill and Gould & Eberhardt shaper to the Bawden Machine Co., Toronto.

The Abitibi Pulp & Paper Co., expects to have the pulp mill at Iroquois Falls, Ont., in operation by July 6th. Construction of the paper mill is being rushed, several hundred men being engaged on the work, but the date by which operations in that department will be commenced cannot be determined as yet.

Toronto, Ont.—The contract has been awarded by the Lake Shore Sand & Gravel Co. to Mills Brothers & Co., Toronto, for an elevator and twin sets of screens and belt conveyor discharge from three bins of the Raymond W. Dull type. The elevator has a capacity of 600 yards per day, and the belt conveyor discharge has a capacity of 300 yards per hour.

The Canada Iron Corporation of Fort William, Ont., have given the contract to the Stevedore Co. of Fort William for an extension of their present dock for a distance of two hundred feet further up the river. The company has at present about four hundred feet of dockage, which is becoming too small for them, as they intend to lay in a large supply of coke and coal during the season of navigation this year.

Catalogues

Wm. & J. G. Greey, Toronto, have sent us a leaflet dealing with improved machinery for many industries. The product described include cake-making machinery, stone paint mills, liquid and paste mixers, trucks and transmission machinery. The leaflet is fully illustrated.

Milling Machines.—The Ingersoll Milling Machine Co., Rockford, Ill., have published an attractive bulletin, No. 26a, entitled "Greater Profits, and how to get them on an Ingersoll." The bulletin contains a number of examples of rapid milling done on an Ingersoll machine, showing the design and the particular adaptability of the tool for the rapid and economical production of duplicate parts. The work illustrated is chiefly confined to milling automobile cylinder castings, accompanied by a brief description.

Link Belt Newspaper Conveyors are dealt with in a graphic manner in Book 195, recently issued by the Link Belt Co., Philadelphia, Pa. The principal features to be noted in the book are the numerous illustrations with descriptions showing the application of the conveyors to the particular service indicated by the title. The illustrations are wholly derived from actual installations and embrace a variety of scope. The book also contains a number of testimonials, a list of plants equipped and a description of the Link Belt Silent Chain.

Milling Machines, made by the Newton Machine Tool Works, Inc., Philadelphia, Pa., are described in catalogue No. 48 which has come to hand. An interesting line of milling machines is dealt with, while in addition are to be noted rotary planing machines, cold metal saws, planing machines, slotting machines, etc. The section devoted to the latter is printed on tinted paper in order to distinguish it from that devoted to milling machines. Specifications are given for the milling machines, and a brief description is given for the other types. Each machine is illustrated, the half-tones being exceptionally good.

Milling Cutters made by the Ingersoll Milling Machine Co., Rockford, Ill., are dealt with at length in an attractive catalogue, No. 30-C. The catalogue contains a complete record of standard and special types of Ingersoll milling cutters, accompanied by excellent half-tones. Tables are included giving the principal dimensions of each size and type of milling cutter, while the reading matter is explanatory of the product. The matter includes particulars of cutter shanks with tables, descriptive illustrations of cutter grinders and No. 2 Ingersoll high-power milling machines. Tables of cutting shears and a complete index conclude an exceedingly well arranged catalogue.

Milling Machines, heavy duty, knee type.—The Ingersoll Milling Machine Co., Rockford, Ill., have sent us a copy of bulletin 31-I, devoted to a description of the above type of milling machines which they make. A complete specification is given of the different types with illustrations, some of which show the machine in operation. Other matter deals

The Ford-Smith Machine Company

Pulley may be covered over with a Special Cap and Machine driven from below if desired.

20-in. Heavy Type, Self-Oiling Polisher

High-Grade Polishing Machines

We build the type shown here in sizes for 16" and 20" wheels, and a lighter type for wheels from 6" up to 18", also self-oiling.

Besides these we manufacture **Double Spindle Machines**, Overhung Machines, etc., and can supply any of above belt or direct motor drive. **You ought to have our latest catalog and further get acquainted with Ford-Smith service, both in regard to delivery and quality machines.**

WE MANUFACTURE MOST EVERYTHING IN THE GRINDER LINE.

The Ford-Smith Machine Co., - Hamilton, Ontario

SIMONDS HACK SAWS

Scientifically machine-milled teeth and unusual hardness and toughness give to these blades their great cutting powers.

METAL STAMPINGS

We are manufacturers of stamped parts for other manufacturers. We do any kind of sheet metal stamping that you require. Our improved presses and plating plant enable us to produce the finest quality of work in a surprisingly short time.

We can finish steel stampings in Nickel, Brass or Copper.

Send us a sample order.

W. H. BANFIELD & SONS
120 Adelaide St. W., Toronto

with fittings, such as rotary tables, cutter arbors and shanks.

Milling Machines, heavy horizontal type, made by the Ingersoll Milling Machine Co., Rockford, Ill., are dealt with in bulletin 28-P, being distributed by the Company. These machines are designed expressly for continuous heavy duty service on locomotive side-rods and connecting rods, and also for railroad shop milling in general. The illustrations are very clear and are accompanied by a brief description covering the principal features of the machine.

Industrial Gas Appliances are dealt with in catalogue No. 2, issued by the Eclipse Fuel Engineering Co., Rockford, Ill. The catalogue contains 167 pages and is divided into ten sections, each devoted to a particular line made by the company. The products include boilers, stills, metal melters, furnaces of all kinds, blowers, heaters, meter cocks, etc., while section ten contains several useful miscellaneous tables dealing with the heating value of oil and gas, melting point of fusible alloys, equivalent value of electrical and mechanical units, circumferences and areas of circles, etc. In addition to the above, there is a deal of information included bearing on the product described in each section which will be useful to users of these appliances and to those contemplating installing such equipment. The principal dimensions are given of each appliance and reference made to the work for which it is best suited. The catalogue is fully illustrated and contains three indexes—to sections, appliances and tables respectively.

Detachable Link-belt.—The Link-Belt Co., Philadelphia, Pa., recently issued advance section (A) of general catalogue No. 110, dealing with the original Ewart detachable link-belt chains and sprocket wheels. This is a very complete catalogue, covering fully the well-known Ewart link-belt chains, attachments and sprocket wheels. The catalogue is fully illustrated, each item being numbered to correspond with the tables which give the price and other information for each type of chain, and also of the various attachments. Some interesting data is included on how to obtain the working strains and horse powers of link-belt chains, while the ultimate strength is given for each standard and special size instead of the working load as in former catalogues. Link-belt drives are discussed at length, accompanied by diagrams showing the action of chains under varying conditions. The section devoted to sprocket wheels includes several tables giving the price and other data for all sizes. This is a very useful catalogue for those interested in transmission machinery.

Columbia Recording Thermometers, is the title of a catalogue just issued by the Schaeffer & Budenberg Mfg. Co., Brooklyn, N.Y., and every operator if he wants to be up to the minute on recording thermometer construction should obtain a copy. It is unusually comprehensive, telling in an interesting way the mission of the recording thermometer in the modern industrial field, its great value to the engineer in helping him to obtain a maximum amount of power from a minimum coal consumption by enabling him to keep strict tab on boiler feed water temperatures, flue gas temperatures, etc. The catalogue is profusely illustrated showing numerous types. Many features outlined will be found to be departures in recording thermometer construction, the removable, adjustable and compensated recording pen arm being an improvement of much value. It makes chart changing easy and eliminates the possibility of errors due to temperature changes at the recorder case. The new patented fume and moisture proof insulation for the steel connecting tubing is worthy of note. It is a thoroughly insulated tubing, practically indestructible and yet flexible. The "Day and Night" border chart which is winning so much popularity commands its share of interest.

Book Reviews

International Conference of Mine-Experiment Stations. compiled by George S. Rice for the Bureau of Mines, Department of the Interior, Washington, D.C. This bulletin, No. 82, consists of a series of conference papers, with minutes of sessions, delivered at a conference comprising delegates from various countries, convened to discuss the question of mine experiment stations, with a view to further increasing the safe operation of coal mines.

The Knack of Selling.—The System Magazine, Wabash avenue and Madison avenue, Chicago, have issued a set of booklets on salesmanship, under the title "The Knack of Selling." These summarize in an attractive and informing way some of the best principles of salesmanship. The titles are "Mapping out the Canvass," "Managing the Interview," "How and When to Close," "Finding and Correcting Your Weak Points," "Getting In to See a Prospect," "Acquiring the Art of Mixing." The books are written in an attractive and readable style, while numerous illustrations from the experience of successful salesmen increase the value of the set. To many salesmen some of the individual suggestions will be easily worth the cost of the whole set of books, which sells for $5. The books are convenient in size and shape to carry in the pocket.

Tests of Bond Between Concrete and Steel, by Duff A. Abrams, has just been issued as Bulletin No. 71 by the Engineering Experiment Station of the University of Illinois. In designing structures of reinforced concrete it is important to know the amount of stress which may be developed between the surface of the reinforcing bars and the surrounding concrete before failure is produced by the slipping of the bars. This stress is what is commonly termed "bond." The above-mentioned bulletin gives the results obtained by pulling out bars embedded in blocks of concrete and also the results of tests made to study the bond stresses developed in large reinforced concrete beams. Nearly 2,000 tests are reported and a wide range of conditions are represented. This is one of the most exhaustive studies of the amount and distribution of the bond stress between concrete and steel which has appeared. Copies of Bulletin No. 71 may be obtained gratis upon application to C. R. Richards, acting director of the Engineering Experiment Station, University of Illinois, Urbana, Illinois.

The Tractive Resistance of a 28-Ton Electric Car by Harold H. Dunn, has just been issued as Bulletin No. 74 by the Engineering Experiment Station of the University of Illinois. This bulletin records the results of tests made with a 28-ton electric car of the double-end type for the purpose of determining the resistance offered to its motion when running on straight level track in still air at uniform speed, and to ascertain the relation existing between that resistance and the speed of the car. The tests were made on sections of straight track representative of good electric railway construction, during generally fair weather when the average temperature was not below 25 degs. F., and when the wind velocity did not exceed 26 miles per hour. The plan of the tests, which involved running the car backward and forward over a selected section of track, made it possible to eliminate wind resistance. The results are finally expressed in the form of a curve whose co-ordinates are car resistance and speed. This curve shows that at 5 miles per hour the car resistance was 5.25 pounds per ton, that at 25 miles per hour it was 13.03 pounds per ton, and that at 45 miles per hour it was 26.12 pounds per ton. The average results from the individual tests did not vary more than 9 per cent. from this final curve. Copies of Bulletin No. 74 may be obtained gratis upon application to C. R. Richards, acting director of the Engineering Experiment Station, University of Illinois, Urbana, Illinois.

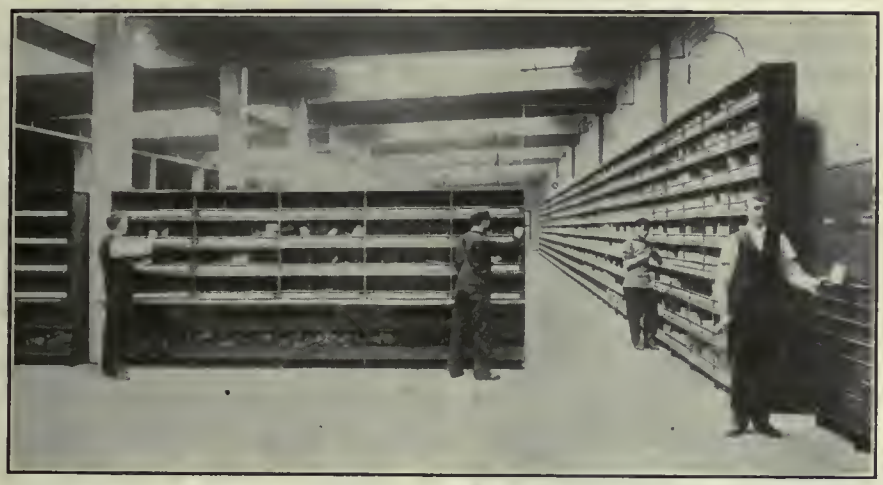
Scientific Arrangement and Operation of a Store-room

By W. G. Astle *

As a factor in the prevention of waste arising from the materials entering into the manufacture of an individual or variety products, the storeroom in its various phases, the more important aspects of which are dealt with in this article, may be reckoned as the greatest.

THE establishment of a storeroom according to scientific principles necessitates a study of the following:—

Effieiency or seientifie management.
Objeet and purpose of the system.
Location of the storeroom.
Physieal arrangement.
Care of the materials.
Method of operation and use.
Results obtained from proper maintenance.



LYON STANDARD RACKS WITH EXTENSION SHELVES AND BIN FRONT ATTACHMENTS.

Definitions of Efficiency or Scientific Management.

The Harrington Emerson definition is "the elimination of all needless wastes in material, in labor, and in equipment, so as to reduce eosts, increase profits and raise wages."

The Roosevelt definition is "applying the eonservation principles to produetion."

The Brandeis definition is "universal preparedness."

The Casson definition is "the securing of a higher percentage of results, by applying seientific methods to the aetivities of the business world."

In an article published in the Review of Reviews, Herbert N. Casson says that "no definition can be very aecurate, for the reason that efficiency is new. Very little of it has been written in books. As a general tendency, it is everywhere; but as a elear-eut system of thought, it exists only in the minds of a eomparatively small number of men."

Object and Purpose of the Stores System.

The objeet and purpose of a stores system is to always have on hand the proper amount of material to meet the regular requirements, but, at the same time to keep the stoek as low as possible consistent with the time and eost of replaeing.

To properly care for materials so that they ean be given out promptly with a minimum eost of distribution.

To know what materials are required to manufaeture the product in the most effieient manner.

To determine the kind and quantity of material on hand at the time manufaeturing orders are put in proeess.

Location of the Storeroom.

The storeroom should be loeated eonvenient to railway or team eonneetion, or both, when the material is such that it will be sent to and from places outside of the factory. To obtain the best location in relation to the other parts of the building, the elevators, aisles, and runways should be given eareful eonsideration, and as far as possible the movement of stoek should be in direet lines as determined by the general routing of the produet through the faetory. A eareful study of this one point alone will very often reduee expenses considerably.

The location as regards the different departments should be determined by the kind and the quantity of material that one department may use, eompared with the requirements of some other department. If one department uses an amount much larger than another, the location should be as near as possible to the department using the greater quantity.

Physical Arrangement.

The physieal arrangement should be sueh that all material can be easily reeeived and distributed when required. It should also have the proper faeilities for preserving the eondition of the material, and it should also be kept safe from disturbanee by outside parties.

In order to handle the material satisfactorily, various kinds of trueks adapted to the product should be used. These will not only facilitate the handling, but will also aid in keeping the material in good condition.

A spaee should be laid out near the entrance of the storeroom for receiving before being placed in the bins or racks. There should also be laid out a space in which out-going material may be temporarily placed. These two spaces should

TERRELL ADJUSTABLE STOREROOM SHELVING.

*Storekeeper, the Toronto Electric Light Co.

be separated so that it will be impossible to make mistakes as far as incoming and out-going material are concerned. The provision of these two spaces will facilitate the work and allow the material called for by stores requisition to be got ready in advance of the time that it is actually required.

In laying out the space required for any particular material, the needs of the manufacturing department should be studied, and standards of maximum and minimum quantities established. From these figures of maxima and minima, the necessary space may be readily calculated. The storeroom should then be arranged, according to the kind of classification used, so that all of one kind will be together, and those of similar kinds next to one another. The bins should be arranged in sections with ample aisle space and good light should also be provided to facilitate the handling and listing.

The exact arrangement will depend upon the nature of the material stored. The most satisfactory arrangement yet found is that in which standard size bins are used, with provision for subdividing and re-subdividing on the unit principle. By this arrangement a large or small bin can be had by simply slipping into the larger one or more smaller units, which allows the material to occupy only the space actually required. If more space is required for a particular material, it can readily be obtained by simply removing the unit subdivision.

Bin and Rack Tags.

Each bin and rack should be provided with a means for hanging a bin tag. This tag should carry the symbol of the stock stored in the particular bin to which it is attached and entries should always be made on it whenever quantities are received or issued, deductions or additions being made with each entry so that it will always show the exact quantity of material on hand. If the materials are arranged according to some type of harmonious classification, it will not be necessary to number the bins in any way. If the material is of a class that this arrangement cannot be satisfactorily used, it will be necessary to number the bins and sections, and to maintain a bin index.

In establishments using the master bin tag, the material is stored wherever it is most convenient, and a bin index maintained. The master tag and one bin tag are placed on the first bin, and the total quantity of material stored is shown on the bin tag. When the original bin is exhausted, both the master tag and the regular tag are moved to the next bin. All bins excepting the original bin have a green tag with the symbol of the material contained therein, and sometimes the number of the original bin.

Care of the Materials.

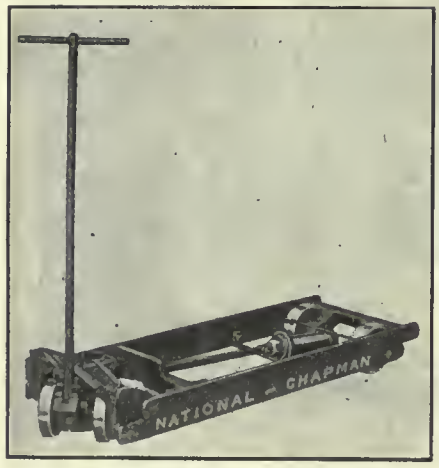
Materials can be divided into three classes, as follows:—

Raw material; being material which is bought to be used in a process before it has been subjected to that process.

Finished commodity and worked material; being material on which work has been done, and material which is introduced into the composition of another product, usually as an accessory part.

Special and accessory materials, such as tools, etc., necessary for a process, yet not actually entering into the completed article, but commonly considered a part of general manufacturing expense, particularly if used over and over, and not directly chargeable against any one particular job.

The location of these different classes of material should be arranged as regards the nature and the frequency with which they will be handled. If handled



TYPE OF ELEVATING TRUCK.

many times they should be stored near the department where used. If handled only occasionally they can be stored in the basement or a shed outside of the regular storeroom building. Consideration should be given to such features as protection from weather, theft, fires, dampness, unusual dryness, etc.

The location and arrangement should be further governed by the fragility, value, weight and the bulk of the material. Consideration of these features will determine what facilities should be provided for the handling, sorting and arranging of the materials and just what provisions for light and heat will be required.

Small materials of great value must be stored in an especially safe place, such as a vault, where the protection against fire and theft will be absolute.

Materials of a delicate nature should be protected from dampness, and materials that suffer from unusual dryness should be stored in a properly humidified storeroom.

Material, such as oils, paints or others of an inflammable nature, should be stored so as to be protected from danger of ignition themselves, and also so that they will not add any undue risk to the remainder of the plant.

Fragile material should be stored so that it will not come in contact with that of a heavier or coarser nature. Unusual weight either of the individual parts or of the great quantity of material stored will necessitate the location of the storeroom upon the ground floor in order that ample support may be provided without undue expense for strengthening the floors and walls of the building. If the materials are light and easily handled and are kept in relatively small quantities, they can be stored in almost any convenient location.

Method of Operation and Use.

Materials that are received from outside of the factory should pass through the receiving department, where it should be thoroughly checked. The receiving clerk should then sort the various kinds of material, attach the lot tag showing symbol, quantity and date received, and enter each item on a receiving report, showing symbol, quantity, date, and from whom received.

Material or parts that are manufactured in the factory and returned to the storeroom for re-issuing are accompanied by a received-in-stores slip showing the symbol, quantity and date. As the materials are received they should be distributed to the proper bins, and the quantity and date received entered upon the bin tags.

The operation of the storeroom as well as the entire system will be simplified if some form of harmonic classification is used. It is the general practise to assign the letter S of the general classification as the first part of the symbol for all materials which have been purchased. This should then be sub-divided for the classified stores and followed by a consecutive number for unclassified or miscellaneous stores which are purchased in small quantities, and which are not usually carried in stock.

Material which is made in the factory and returned to stock for future use in connection with other parts for the completion or assembly of some article should be carried under some letter or letters of the general classification which would indicate the particular product for which the parts are used. This class of stores is termed "worked materials" to distinguish them from stores that have been purchased. These classes should be further sub-divided by letters and numbers to indicate the part itself. Such a classification worked out to cover the entire stores of a factory enables the material itself to be arranged consecutively in the bins in the storeroom.

If the storeroom be operated on the double bin system, the main bin, assigned for a particular kind of material, should be divided into two parts, and in each part should be placed the standard quantity, and the tag attached to the materials by the receiving clerk should be placed on the hook for that section of the bin. Stores requisitions should then be filled from one section of the bin until that quantity is exhausted, at which time the bin tag for that section should be taken off and sent to the storekeeper as a notice that the quantity on hand has reached the minimum, and that an order for the standard ordering quantity should be placed. Any stores requisition received after that should be filled from the other division of the bin. The maximum and minimum quantities should be so fixed that there will always be a part of a lot in one section of the bin. It is seldom necessary to carry more than two lots at any one time; that is, one complete lot in each section of the bin.

The maximum or ordering quantity should be large enough to enable the purchasing agent to take advantage of low prices, slow delivery, or any other market condition that would result in economy where purchasing; or if the materials be made in the factory, advantage should be taken of convenient and economical manufacturing quantities. The minimum should only be large enough to meet the requirements during the time required to secure the maximum by manufacture or by purchase.

When the materials are such that the amount on hand is subject to great fluctuation in quantity, or is not carried at all during certain portions of the year, it is more economical of space to arrange them in bins that may be available at the time. In such a case it is necessary that the bins should be numbered and a bin index showing location of each kind of material maintained. Under the single bin system these maximum and minimum quantities are carried on the balance-of-stores sheets, while with the double bin system the minimum is one lot, the ordering quantity one lot, and the maximum that seldom will be exceeded is two lots.

No material under any consideration should be given out without a stores requisition, showing the symbol of the material, the quantity and any other particulars necessary. Upon the receipt of this requisition the stock clerks should remove the material called for from the bins, make the proper entry on the bin tag, attach an identification tag to the material and place it in the outgoing section of the storeroom, where it should remain until the move-man presents a move order calling for delivery. When the material has been issued the storekeeper signs the requisition and sends it to the accounting department.

When the material has been issued for an order in excess of the amount required, the balance is returned to the storeroom, accompanied by the proper credit slip, which is signed by the storekeeper upon receipt of the material. He then places them in their proper location, and the credit slip is sent to the accounting department.

Results Obtained From Proper Maintenance.

If this department of a business be properly maintained, the following results will be obtained, which will more than pay for the operation of the storeroom, and will give facts and information which cannot be obtained in any other way:

The elimination of waste due to improper care, and to carrying stock over from year to year which has become obsolete, instead of disposing of it or using it at a time when it is of value.

Materials will be ready when wanted, and will be available in such quantities as are needed.

Ability to fix responsibility for errors.

The prevention of tying up material and labor in process on account of the shortage of some material which has not been provided.

Ordering and purchasing material becomes a matter of routine nature.

The amount of space required for storage will be less under a proper stores system, because the amount carried will be smaller and the arrangement more economical, and the consequent overhead charge for floor space will be reduced accordingly.

A knowledge will be had of the exact quantities required for economic manufacture and for running machines or jobs in the best manner for the proper fulfilment of orders.

The better care of stores of all kinds.

Ability to replenish your stock automatically when it is getting low without unnecessary delay.

The prevention of tying up material in over-large quantities and a consequent saving in the money invested in the material and in the interest charge on this money.

Ability to route material direct from the storeroom to the job or machine where it is needed, instead of delaying progress on account of the time required to purchase and secure delivery from outside.

The maintenance of a balance sheet, which shows not only the amount on hand in the storeroom, but the amount ordered, the amount available for future orders, and the amount drawn out for use during any period.

Simplicity of control with less labor to operate and a consequent smaller cost for handling the same amount of material.

If the system be properly maintained with competent help, the taking of the annual inventory becomes an easy matter; it will also be accurate. It consists of simply taking off from the balance sheets and on to the inventory sheets the quantities in the storeroom, the quantity in process, together with the cost or value. This method is perfectly practicable, but in order to obtain accuracy the help in the storeroom must be competent and all work should be checked and inspected in a routine manner.

FOUNDRY REGULATIONS.

The British Home Office have issued the following proposed new regulations governing the casting of iron and steel:

1.—Where iron plates are used in a molding shop, either as gangways or under furnace spouts, they shall be kept constantly dry.

2.—Where molten metal is carried by hand between rows of molds or boxes, a clear passage way, not less than 18 inches in width, shall be provided and maintained between such rows.

3.—Where molten metal is conveyed across an open space, a clear passage way, dry and covered where practicable, shall be provided and maintained between the cupola and the place where casting is done.

4.—No person under 16 years of age shall convey or assist in conveying molten metal.

5.—Requisites for treating wounds and burns shall be kept at hand, and be placed in charge of a responsible person.

6.—All chains used for lifting or moving any material shall have been tested and shall be periodically examined, a register being kept on the premises, containing the distinctive mark or number of each chain, the date of each test and re-test, the test load, the safe working load and the dates of annealing or firing.

7.—In any part of a molding shop where molten metal is caught, conveyed, or poured, adequate protection for the feet shall be provided and maintained in proper order and repair for the use of all persons employed.

The power of a man increases steadily by continuance in one direction. He becomes acquainted with resistance and with his own tools; increases his skill and strength and learns the favorable moments and favorable accidents. He is his own apprentice, and more time gives a great addition of power, just as a falling body acquires momentum with every foot of the fall.—Emerson.

Management--The Efficient or Waste-Eliminating Type

By E. St. Elmo Lewis *

The present is the final of a series of three articles which deals with the subject of management as exemplified in three different types of men—the strenuous, the systematic and the efficient. The points brought out relative to the useful accomplishment and otherwise of each are worthy of careful study.

THE efficient manager has one object constantly before him—the elimination of waste. He realizes that every bit of material in his place can be used at 100 per cent. efficiency or less; that every bit of energy that he pays for can be used at 100 per cent. efficiency or less; and that time can be used in the same way. He knows that things do not happen; that there is a cause for every effect. He knows, also, that men can be taught, for he is teaching them. He knows that stenographers in an office can be taught accuracy, speed, English, or how to write a letter. He takes from his department manager the time-wasting job of acting as primary school teacher to his stenographers.

He knows that foremen should simply supervise, they should not be expected to teach men the best ways of doing work. He knows that men vary in capacity, but he knows also that men learn to do better work at twenty-five than they did when they started as apprentices; that the best men have a certain way of doing things that can be taught to others, and therefore a plant can be taught how to increase production. It is a question of analysis, planning and executing. Therefore he goes at the proposition of raising efficiency in a definite, concrete, tangible way, something like this:

Plan Starting Point and Purpose.

1.—He makes time studies of the work.

2.—He places these studies in the hands of trained thinkers and scientific men who plan the work and fit the schedules.

3.—He establishes the idea of functional foremanship.

4.—He makes improvements in shop methods necessary to get the greatest possible product from the worker.

5.—He puts a wage system at work that will place a premium upon a man who exercises the greatest efficiency. A big problem? Of course it is, but it must be solved, must it not? Its bigness does not affect its pressing call for a solution.

The efficient manager, after analysis, adopts a plan starting with the Taylor System, or the Emerson System, or any one of many, which all come under the general term of scientific management. He starts from somewhere to go somewhere in his management.

Suppose he decides to start with the Emerson system. He tests his present management against the twelve Principles of Efficiency, as Mr. Emerson calls them:

1.—Definite plans and ideals.
2.—Supernal common sense.
3.—Discipline.
4.—Competent guidance.
5.—The fair deal.
6.—Despatching.
7.—Reliable, immediate and adequate records.
8.—Determination of standards.
9.—Standard practice instructions.
10.—Standardized conditions.
11.—Standardized operations.
12.—Efficiency reward.

Department Sequence.

While this is not a treatise on general efficiency but on cost keeping efficiency, intended to show how to eliminate the waste of time, work, thought, material (all of which spell m-o-n-e-y in business) in the handling of costs, yet it is necessary to explain the philosophy of efficiency if we are to handle costs efficiently. "Increase the net," is the cry, and no manager can escape the necessity for knowing the value of what he does when it comes to costs any more than he can of any other part of his work. Every manager should realize that all work in a factory or in an office goes by dependent sequence. No man's work stands alone.

The other day a manufacturer was asked what he thought his efficiency was in different departments. He said, "He thought that his efficiency was 75 per cent. at least," and he forgot the law of dependent sequence. If the raw stock department was 75 per cent. efficient, and the department to which it first went 95 per cent. efficient and the next two were each 75 per cent. efficient at the end of the fourth operation, the end result would be only 40.1 per cent. If each of the four departments were 80 per cent. efficient, the end result would be 41 per cent.

If one department were 75 per cent. efficient and another department were 125 per cent. efficient, the end efficiency would only be 93.75 per cent. The efficient manager, therefore asks of the cost department such records as will assist in the establishment of a complete record of the efficiency and of how much it has cost to gain the amount of efficiency that has been attained. Values must be established as well as costs, and for this purpose we must have every order that goes through a plant, every function of department standardized, establishing the best as a standard of value, by which to judge our efficiency. Out of that will come the best rate of pay for each man or woman, the proper number of people to be employed in doing a particular job, the kind of men best suited for each kind of work, and the standard time for its operation. These standards should be indicated on the same records by which the system tells the actual things that were done in the course of the work. In other words, it should show standards as well as performance on each record.

If the comptroller be necessary to show where money goes, then the efficiency manager is necessary to show what is obtained for the money. The cost accountant should be concerned principally with arranging his systems of cost-keeping so that reliable, immediate and adequate records may be kept of the value of the commodities received for the money invested. The same record should show the comptroller or auditor where the money goes, and the manager where standards of value have been realized, and where losses are occurring in time, labor and material.

The Cost Accountant Feature.

In the past the cost accountant has too frequently been merely man of figures, having little or no conception of what the figures really meant. He was essentially a bookkeepeer who didn't know the significance of the things he was handling, and he was only concerned with totals, averages, percentages. So long as he secured his balance, he was satisfied with his results. He knew of no standards for comparing with values. He failed to realize that accounting really consisted of balance sheets to be used as efficiency charts. Balance sheets can be veritable miles of misinformation, for paper profits have mislead many a manager. A plant can be made to show fine profits on the balance sheets for a time, but efficiency charts would show up the starvation at a glance.

Before the cost accountant can become efficient, the management must become efficient. If the management is not efficient, the cost work will not be organized and functionalized so that it can reflect truly, adequately and completely

*Advertising Manager, the Burroughs Adding Machine Co., Detroit, Mich.

the real value of the business performance; therefore, the cost accounting has to reflect what is actually being done. No matter how efficient the cost accountant may be, he cannot make an inefficient plant or an inefficient organization efficient. He can reflect only what an organization is doing, showing blanks for those kinds or records which the management handling the business does not permit him to make.

On the other hand, no matter how efficient may be the plan or organization, no matter how efficient may be the individual members of the organization, if the cost accounting records are not efficiency records, there will never be any adequate information placed before the comptroller or the general manager that will give them an oportunity to accurately guage, in the first place, what has been received for the money, and in the second place, where inefficiencies may be eradicated.

Waste a Large Fixed Charge.

The manager under any efficient plan of organization must realize that wastes, principally those which he does not now see are the most vital concern of management. The "doer" type of American manager wants volume of production, volume of sales, volume of this and volume of that. He doesn't realize that effieiency is concerned with the net. That is the final as well as the primal test of his efficiency, of his real worth to the organization. An engineer of national prominence said the other day—"It is absolutely bewildering to note how managers will permit continuous, relatively large wastes to continue rather than incur a pay roll expense that will stop it." Let such men understand that waste is the largest "fixed charge" in most factories."

The efficient manager will, therefore, develop his cost system along the line of obtaining efficiencies as against standards set up by those who are most familiar with what machines and skilled men can produce when all these highest efficiency of production. He knows a cost system to be a means to an end, and not an end in itself. He knows that knowing costs is but the beginning of knowledge, and that unless he has some ideal standards with which to compare his costs he is still running the business with but half the information necessary to realize its greatest possible success.

Manager Type Differences.

What is the real difference between the rule-of-thumb manager and the the systematic manager? The former guesses at what happened and the latter knows what happened. Neither necessarily knows what the value of the happening really is—the latter knows what it cost, the former can't be sure, but he can pay his bills—sometimes.

The difference between the systematic manager and the efficient manager is fundamental. The former occupies his time in writing history. He is thinking of yesterday; he is always at least one day behind the work; generally he is from a week to a month behind. The efficient manager is writing propheeies. He is scientifically determining what is going to happen the day after to-morrow. He is systematic, too, hut his system is projected into the future. He does not care what happened last week. He is never later than to-day. He was preparing for to-day six months ago.

Step into a great business—get behind the scenes a moment, peer into the laboratories. There are unique furnaces for steel-making, there are schools for man training, there are machines that will not be placed on the market for five years — there are careful analysis of markets to be developed two years from now. Researches are being made—men with note books and open ears and eyes are traveling—engineers are experimenting—all preparing for to-morrow.

When the day comes these managers go ahead methodically developing their day-before-yesterday plans, and the game of doing business pays for the prophetic vision. As battles are not fought under the inspiration of the moment," so the efficient manager never waits for the fighting. He always forces it."

That is the difference between the various types of managers—the difference between their business—the difference between their cost systems. It appears in the net!

Cupola versus Air Furnace in the Foundry

By "Melter"

The writer is not the least sanguine as to the displacement of the cupola by the air furnace, a conclusion easily noted in both the opening and closing sentences of the article. The subject, however, is one of deep interest to foundrymen, and we shall be glad to have experiences and expressions of opinion from those who have had the opportunity of making the necessary comparisons.

WHETHER the air furnace has come to stay, as was intimated by U. K. N. in his article in a recent issue of your journal, is a very interesting question. The outstanding features as I view them are:—

The air furnace is principally used for melting iron to be turned into malleable because the silicon and carbon can be accurately controlled and the burning out process stopped at the required point. Malleable eastings commonly contain a total carbon content of 2.75, which was possibly reduced from 3.50 and a silicon content around .60 per cent. reduced from silicon .80 to 1.2. Malleable is however, largely being supplanted by steel in the car industry.

My experience has been that very little scrap is being used on account of the difficulty of averaging up the analyses of the scrap pile, which would possibly vary more in sulphur and phosphorous than in any other elements. Both of these, however, are necessary up to certain points. Phosphorus up to about 0.7 per cent., has no apparent effect, while sulphur which has been assumed to be the cause of so much trouble to the foundryman in the past is now being used up to .18 per cent. in chilled iron and as high as .20 per cent on occasions in the grey iron foundry. When melted hot it gives no trouble, but just how much sulphur one might allow to be present depends upon the manganese content, for the bulk of the sulphur not present as manganese sulphide is present as iron sulphide which is more brittle.

Manganese sulphide unites in drops while iron sulphide spreads out in sheets producing lower ductility and strength. The freezing temperature of manganese sulphide, about 2,550 degs. F., is much nearer the melting point of the iron, while iron sulphide solidifies at a very much lower temperature, thereby producing inequalities in the iron. This difference in the coefficients of expansion are what cause hot shortness as they occur at a red heat. The air furnace metal takes up from 1/100 to 8/100 of 1 per cent. sulphur from the gases, but, as pointed out above, the sulphur content can be neglected if sufficient manganese is present, and if enough silicon be added to counteract the effect of sulphur on the production or rather retention of carbon in the combined form which effect is about fifteen times as great. In other words each .01 sulphur is equivalent to .15 silicon.

If a cupola be carefully lined, patched up to preserve the right contour, blast pressure adjusted uniformly depending upon the size of cupola and grade of fuel, slagged periodically, coke and iron charged carefully and the latter thoroughly sized and mixed on the buggies before charging, as is done in any well regulated foundry, there should and will

not be enough variation to be noticed by transverse or tensile tests. The only noticeable points, and then only on low silicon irons, will be on chill tests due more to temperature conditions than to large variations in analyses.

Comparative Analyses.

Results of analyses, transverse and tensile tests on cupola and air furnace irons from my observations show an increase in strength of approximately 6 per cent. in favor of the air furnace.

	Cupola.	Air Furnace.
Silicon	1.8	1.8
Manganese	.5	.7
Sulphur	.13	.08
Phosphorous	.55	.40
Combined carbon	.70	.70
Graphitic carbon	2.80	2.80
Total carbon	3.50	3.50
Transverse test, 2,700 to 3,100 lbs.		2,900 to 3,300 lbs.
Deflection	.15 to .20	.17 to .22
Tensile strength. Lbs. sq. in.	24,000 to 28,000	27,000 to 30,000

The bars are of the American Society for Testing Materials standard, and are 1¼ in. diameter cast in dry sand and tested on 12 ins. supports. After they are broken, one-half is turned in a lathe for tensile test.

The principal points involving the physical properties of cast iron are:—Hardness, grain structure, shrinkage, fluid properties, resistance to heat, strength, elastic properties, resistance to wear.

My observations have shown that melting just hot enough to pour castings ¼ in. thick and getting them good gives the strongest metal for high silicon (silicon 2.00, manganese .50, total carbon 3.50), and where the silicon is low the colder the iron the stronger the bars. Bars slightly and uniformly mottled all through give the highest bar strengths. The rate of cooling through the solidification range or the establishing of a high melting zone (consequently melting quickly), and melting just hot enough and no hotter governs the size of graphite crystals, for in the case of high silicon irons the graphite separates within the semi-liquid iron and gives the crystals of graphite more chance to grow larger, whereas the graphite in iron melted at a lower temperature and formed within the solid metal will not have such large graphite plates. All these points may be adjusted with as much ease in cupola as in air furnace melting.

Comparative Melting Cost and Speed.

The cost and speed of air furnace melting are the greatest factors in determining whether the air furnace has come to stay or not. Speed is important because in foundries where cupolas are in operation it takes three hours to melt 45 tons of iron and an air furnace requires from four or five hours for the same tonnage.

Cupola.

Pig iron, 1,500 lbs.	$16.6
Steel, 1,000 lbs.	5.8
Scrap, 2,500 lbs.	19.25
80% Ferro-Mn., 30 lbs.	.75
Cost of tapping, weighing and charging	.60
Fuel, 630 lbs.	1.97
	$44.97
Cost per 100 lbs.	90c.

Air Furnace.

Pig iron, 5,000 lbs.	$46.9
Steel, 1,000 lbs.	5.8
Scrap, 2,000 lbs.	15.4
Coal, 2,000 lbs., $6 per ton	12.0
Cost of tapping, weighing and charging	5.28
	$85,38
Cost per 100 lbs.	$1.67

Difference per 100 lbs. in favor of the cupola, 16.7 cents.

The cost of coal may seem excessive but where hand firing is done it is necessary to obtain best results to have a long flame coal with an analysis of approximately:—

Total volatile matter	38.1
Fixed carbon	54,8
Ash	7.1
Sulphur (low)	8.2
Total combustible matter	92.42
British thermal units	14,270

When using pulverized coal this cost may be reduced considerably.

Tapping Air Furnace Iron.

As to the difficulties experienced in tapping air furnace iron in small quantities I have not been up against the proposition. Generally, in malleable plants the moulders line up and catch hand over hand from the spout and pour it back into the furnace, in this way mixing the iron thoroughly. This is advisable if a silicon addition has been made and if the furnace was charged cold. The iron on the top which is subjected to the direct flame is far hotter than that underneath. When ready the iron is retapped as before, and if castings are two hundred pounds or so, two or more moulders are employed. As to varying the depth of chill on rolls this can be accomplished by using varying sized chillers, heating the chillers, taking iron at different temperatures (in low silicon irons the colder the iron the more chill), and tapping the furnace before the silicon and total carbon is at its lower point.

One of the largest piston rings manufacturers in the United States is turning out a gun iron melted in the air furnace and comparative results show that there is nothing in favor of air furnace over cupola melted iron. In my opinion the cupola will never be superseded by the air furnace, but one of these days electricity will take care of the melting of iron for metallurgical purposes.

APPROPRIATENESS OF MATERIALS.

By A. E. S.

THE great amount of time and thought given to the design and composition of bearings has resulted in the production of very high-class anti-friction journals and boxes for rotating parts. It is peculiar that an exceedingly well-trained designer will often, after accomplishing the above, give little attention to other equally wasteful sources of friction and will construct mechanisms regardless of the rule that friction is greater between similar substances than dissimilar ones.

In plants where much large and important machinery is made the writer has noted that little attention is paid to making pistons, piston rings and engine cylinders of different and most suitable grades of iron. We have seen cross-heads and guides cast from the same ladle at the same time where much could be gained even by casting one of the wearing surfaces at the beginning of the heat and the other near the end.

Great improvements have been accomplished by chilling the bearings for tumbling barrels and casting the journals of soft gray iron. The remarkably long life of modern high-speed gasoline and air engines can, in many cases be attributed to making cylinders of a hard close grained iron and annealing the pistons or vice versa. Great virtues have been attributed, and in a great many cases rightly, to Muntz metal, Monel metal and similar compositions, which, under conditions where non-ferrous metals are essential, accomplish the same thing that could be brought about by varying the composition of the brass.

When it is realized that with the aid of grinding machinery, castings can be machined when harder than a file, and that by annealing suitable gray iron it can be made soft enough to cut with a pocket knife and to machine at 600 ft. per minute, some idea of the variety of iron available can be the better realized.

There is no doubt that very much has been accomplished along these lines by the larger specialty manufacturers with the aid of analytical chemistry. There remains, however, a great deal to be accomplished by the man who builds expensive machinery in small quantities or single units with the help of judgment and horse sense.

PRODUCTION METHODS AND DEVICES

A Department for the Interchange and Distribution of Shop and Office Data and Ideas Evolved from Actual Practical Application and Experience

BORING MILL PRACTICE.—I.

By Albert A. Dowd.

THE vertical type of turret lathe is a machine of great manufacturing possibilities when in the hands of a competent operator and supplied with a full complement of tools. It can also be used to advantage for single piece work with a very modest equipment. The excess of power which is a feature of the machine and its great adaptability to various conditions, together with its convenience and rapidity of operation, makes it

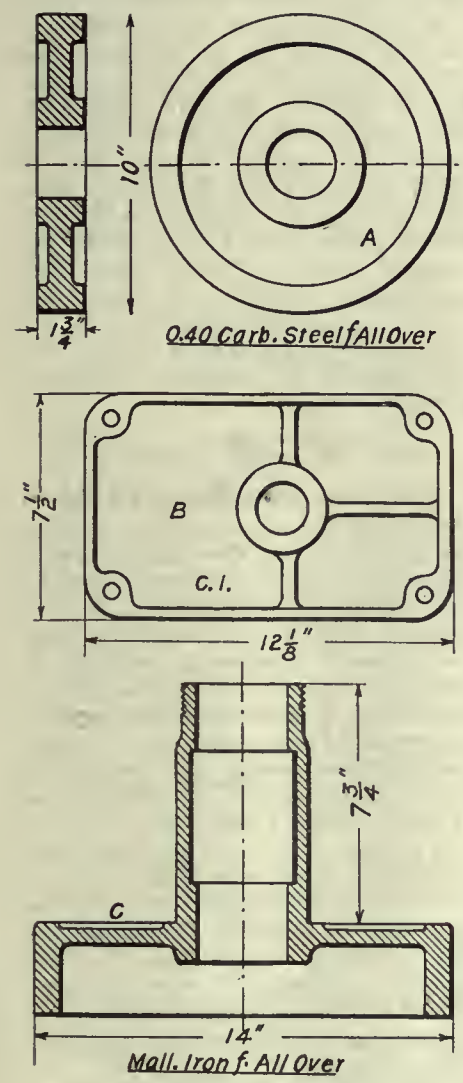


FIG. 1—EXAMPLES OF SINGLE PIECE WORK.

especially desirable for odd jobs requiring heavy cutting and a great saving in production time can be effected by its use providing the tool equipment is carefully selected. In using this type of machine for single piece work there are several important points which have an influence on the rapidity and accuracy with which the work can be handled.

Important Points in Handling Single Piece Work.

First.—The skill of the operator is one of the most important factors in handling work of this character, and in addition to his ability in this regard, he must also be a man who is quick to understand the important points in the work and one who can read a blue print rapidly. If the shop conditions permit, it will be found advantageous to allow one man to handle as much of this single piece work as possible, for his familiarity with his tools will allow him to use the machine much as another man would use a lathe on which he might be at work constantly.

Second.—There should be a conveniently accessible rack or table on which the tools and holders necessary for this class of work can be kept. These should be considered as a part of the equipment of this particular machine and should not be kept in the tool crib or borrowed by other men.

Third.—The tool equipment itself must be carefully selected according to the general class of work to be handled. All cutting tools should be of high speed steel and should be well kept up so that they will be ready for use at all times. A good operator will attend to these matters without being told.

Fourth.—The equipment of jaws, clamps, plugs, bushings and bolts must also be carefully looked after so that when changes in setting become necessary, the means will be at hand by which the work can be profitably handled. A few shims and a set of size blocks will also be found valuable aids.

Examples of Single Piece Work.

Figure 1 shows several examples of work which can be very profitably handled on a vertical turret lathe even when only one piece at a time is wanted. The upper illustration A is a forged (hand) gear blank of 0.40 carbon steel, about 10¼ diameter by two inches thick in the rough state, and somewhat irregular due to its being hand forged. It is to be finished all over to the dimensions shown, and no work has been done on it except the rough drilling of the hole ¼ inch undersize.

The middle figure B is a bracket having an internal hub eccentric to the outside of the casting. This bracket is of cast iron and is to be faced on one side along the edges and the hole is to be bored and reamed. General dimensions are given on the drawing.

The lower Fig. C in the illustration is of malleable iron and is to be finished all over, although the relieved portion of the web is simply roughed out, being afterward painted so that no great accuracy is required at this point. Attention is called to the fact that the inner surface of the hub is relieved, while the upper end is threaded.

Tool Equipment for Single Piece Work.

Fig. 2 shows a group of tools, holders, etc., which will be found adapted to a wide variety of work. Nearly all of these are standard and can be bought of

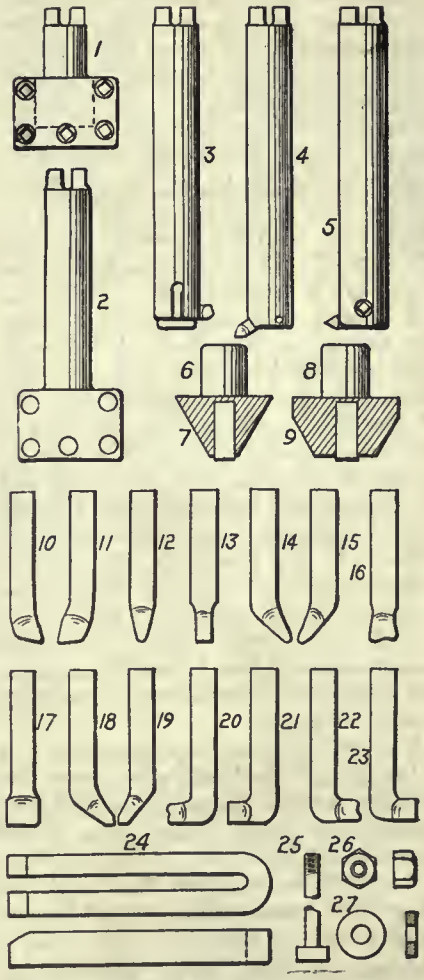

FIG. 2—TOOLS AND HOLDERS FOR A WIDE VARIETY OF WORK.

the manufacturer at reasonable prices, while those which are of special design may be very easily and cheaply made.

Nos. 1 and 2 are respectively regular and extra long tool holders for use in the turret, and designed to hold any of the forged tools. These holders are slotted to receive the tools and are provid-

ed with set screws by which tools can be firmly held.

No. 3 is a combination boring and reaming bar having a series of "slip cutters" for boring and reaming holes of various diameters. These cutters may be bought in sets for any specified size of hole, one bar being sufficient for a number of sizes when provided with the proper cutters; three sizes of bars are enough to cover a wide range of work with cutters for standard size holes. The reaming cutter floats in a slot, thereby obtaining much the same result as a floating holder.

No. 4 is a regular bar having an angularly placed cutter, which may be used for turning, facing or boring, while No. 5 is a thread chasing bar which can be used for either external or internal threads in connection with the thread chasing attachment of the machine.

No. 6 is a steel stem on which a conical shell 7 is mounted for the purpose of roughly centering the cores in irregular work. Nos. 8 and 9 are for the same purpose but of larger diameters.

The group of forged tools Nos. 10 to 23 inclusive is sufficient to cover almost all conditions which may come up in the general process of handling single piece work. No. 10, 11, 12, 14, 15, 16, 20 and 22, are roughing tools, while the remainder are used for finishing. Nos. 16, 17, 20, 21, 22, 23 are special, but all the others are standard tools.

Nos. 10 and 11 are intended principally for use in the side head for heavy turning operations, and they can also be used for facing or undercutting. No. 12 is a plain round nose tool the uses of which are manifold. No. 13 is a finish facing or grooving tool. Nos. 14 and 15 are right and left turning and facing tools for roughing operations, and they will cut in two directions. No. 16 is a special roughing tool which can be used to cut in three directions, while No. 17 is a finishing tool having the same characteristics. Nos. 18 and 19 are right and left finishing tools for the same purpose as 14 and 15.

Nos. 20, 22, 21 and 23 are roughing and finishing right and left offset tools for shoulder work or something of a similar nature. All these forged tools should be made in duplicate. The U-straps, bolts, nuts and washers, 24, 25, 26 and 27 are very important and should be provided in several sizes.

Machining a Plain Spur Gear Blank.

It is important in setting up a machine for single piece work of constantly changing character, to so select the turret and slide head tools so that as few alterations as possible will be required when handling the various pieces. The turret and side head set-ups shown in Fig. 3, will be found capable of handling a considerable variety of work with very little changing. The three tool holders F, J and L are placed as shown in the main head turret and are provided respectively with the starting tool E, and the roughing and finishing tools K and M. The combination boring and reaming bar N is provided with cutters for boring as shown at O and slip floating reamer blades P, for sizing the hole. The side head tools Q and R are respectively rough and finish facing and turning, while S and T are shoulder tools.

The table of the machine is of the three-jawed universal type having a set of standard jaws C, by which the work is centered and held. In this instance

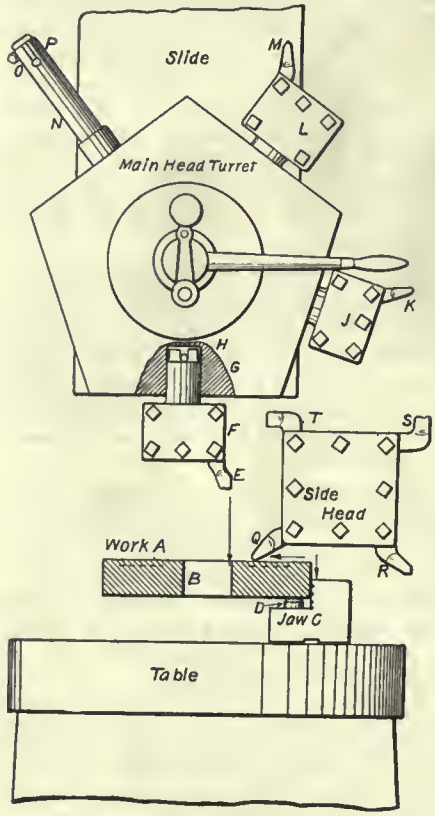

FIG. 3—SET UP FOR PLAIN SPUR GEAR BLANK.

a set of raising buttons D is used to support the blank A so that a part of the periphery may be turned at the first setting in order to provide a method of holding for the second setting. These buttons rest in the screw holes of the jaws and are obviously all of the same height.

In machining this piece of work, the main head is set over beyond center sufficiently to enable the starting tool E to remove a little of the surplus stock in the hole to a diameter slightly smaller than the first boring bar tool O. The side head tool Q is started on the facing operation and the starting tool removed by indexing the turret until the tool K is in position, after which it is started facing out from the center, and the side head drawn back out of the way and used for partially turning down to the top of the jaws, as indicated by the arrow.

The offset roughing tool S in the side head is now brought into use to cut the relief shown by the dotted line and after starting the feed out away from the center, the main head turret is indexed and the facing tool M follows closely after it for the finish facing. The tool R in the side head finish turns the periphery while the facing tool in the main head is completing the facing operation. The table is now speeded up and the boring and reaming bar N finishes the hole to size. It is advisable to allow a few thousandths for the final finishing of the periphery, this final cut being with the tool R. The piece may now be removed from the table and laid aside for the time being unless it is wanted immediately.

If any other work of a similar nature be waiting to be machined, this should be placed on the table and machined before the jaws are changed for the second setting of the gear blank. A considerable amount of time can be saved by using a little forethought when handling work of this character, by combining several jobs so as to avoid the constant changing of chuck jaws. It is not always possible to do this if the work be required in a great hurry, but it is well to bear it in mind so as to take advantage of the situation whenever possible.

Lubricating Wire During Drawing.—According to a recent patent for lubricating wire during drawing, lubricating material combined with organic binding material is applied to the wire, and the binding material is carbonized to cause the lubricant to adhere to the wire. A suitable lubricant is made by incorporating glucose or cane sugar with graphite stirred up in water; one pint of the material known under the trade mark "Aquadag" is mixed with 2½ pints of water, to which is added about 70 c.c. of the glucose solution sold as "Karo Korn syrup" or cane sugar boiled down to molasses. Suitable preservative, such as a solution of bichloride of mercury, may also be added. The preparation may be applied by drawing the wire through a vessel or cotton waste containing it, or by passing it over a grooved pulley running in the liquid.

Le Pas, Man.—A contract has been awarded to the Canadian General Electric Co., for motors, and to the De Laval Steam Turbine Co., of Trenton, N.J., for two 250-h.p., two-stage centrifugal pumps and two 10-h.p. vertical single-satge pumps.

Arithmetic for the Machinist and Workshop Operative

By J. H. Rodgers

With the further development of this course in arithmetic, it will be found by those who have followed the introductory lessons and profited by them that the various practical applications resulting from the succeeding lessons will be easily observed and their time and labor-saving features so appreciated as to be adopted at every available opportunity.

TAPER WORK.

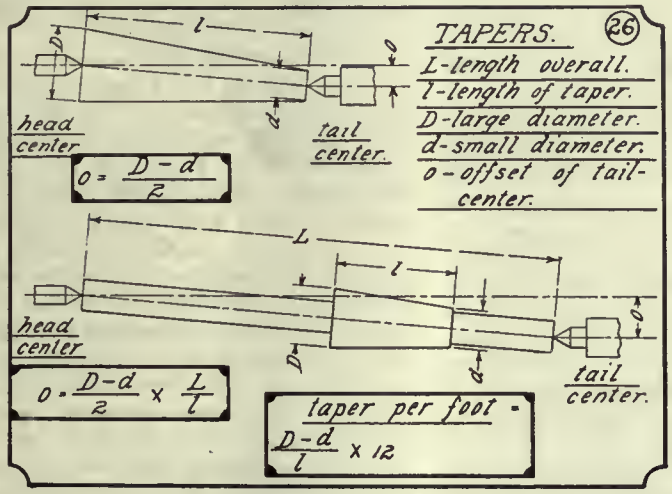
IN calculating for the offset of the tail-stock center or angle of inclination of compound rest or dividing head on the milling machine, or other means whereby the necessary results are obtained, some interesting and often apparently difficult problems may be involved, but by a close scrutiny and an application of some already noted principles, many, if not all, of these seemingly cut-and-try methods may be accurately solved by the use of a few formulae and the knowledge of how to apply them. When offsetting the tail-stock center to cut a taper, extremely accurate results cannot very easily be obtained, due to the varying depths to which the centers go into the work; but for very close approximate results the formulae on chart 26 are given.

When the taper to be turned forms only a fraction of the total length, use the formula, $O = \frac{D-d}{2} \times \frac{L}{l}$, where L = length overall, l = length of taper, and D and (d) same as before.

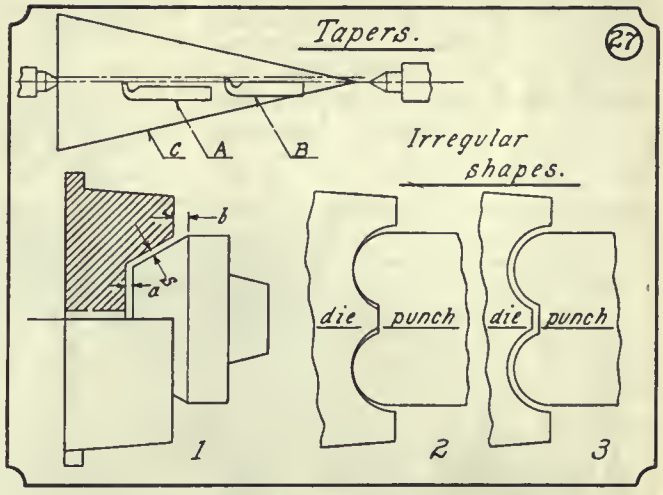
Example:—A piston rod 3 ft. 2 in. long has a taper end with a length of 6 in., large diameter 2¾ in. and small diameter 2½ in. Find offset of tail-stock center.

By formula, $O = \frac{D-d}{2} \times \frac{L}{l} = \frac{2.75-2.5}{2}$

$\times \frac{38}{6} = \frac{.25}{2} \times \frac{38}{6} = \frac{4.75}{6} = .791$ inches, or $\frac{51}{64}$ in. nearly.



ARITHMETIC CHART 26.



ARITHMETIC CHART 27.

If the taper run the full length of the work, or from center to center use the formula $O = \frac{D-d}{2}$, where O = offset of tail-stock center, D = large diameter and d = small diameter.

Example:—A tapering plug (frustrum of a cone) is required, large diameter 8 inches, small diameter 5 inches, and length, 14 inches. Find offset of tail-stock center.

By formula, $O = \frac{D-d}{2} = \frac{8-5}{2} =$

$\frac{3}{2} = 1\frac{1}{2}$ inches.

Example:—A shaft similar to that shown on chart 26, is required, having an overall length of 5 ft. 3 in. The tapering part (l) has a length of 8 inches and a taper of ⅛ in. per foot. Find offset of tail-stock center.

Here the equal of D—d is the taper per foot multiplied by the length overall in feet; or $.125 \times 5.25 = .656$, then

$O = \frac{.656}{2} = .328$ inches, or $\frac{21}{64}$ ins. nearly.

When cutting tapers, care should be taken that the cutting edge of the tool is the same height as the centers, otherwise the work will not be true. As all tapers are cones or frustrums of cones, it is obvious that the only possible straight line will be from the apex to the base, therefore the cutting tool must travel upon this line; see A, chart 27.

If the cutting edge of the tool be not on a level with the lathe centers, each additional cut will show a different taper.

In fitting tapers or odd shapes in forming tools for bar stock or sheet metal, allowance must be made for the necessary stock. To form the stock, the space (a) and the space (s), chart 27, will necessarily need to be the same, but if the punch be lowered so that the faces (a) come together, there will still remain clearance between the two faces at (s), due to the vertical travel of the punch. This may be more clearly shown at 2 and 3, where 2 shows the punch resting freely in the die, while at 3 the error will be in proportion to the position in height of the tool. This may be easily seen when fitting tapers. If the tool be not on a level with the lathe centers, each additional cut will show a different taper.

In fitting tapers or odd shapes in forming tools for bar stock or sheet metal, allowance must be made for the necessary stock. To form the stock, the space (a) and the space (s), chart 27, will necessarily need to be the same, but if the punch be lowered so that the faces (a) come together, there will still remain clearance between the two faces at (s), due to the vertical travel of the punch. This may be more clearly shown at 2 and 3, where 2 shows the punch resting freely in the die, while at 3 the error will be in proportion to the position in height of the tool. This may be easily seen when fitting tapers. If the tool be not on a level with the lathe centers, each additional cut will show a different taper.

If the cutting edge of the tool be below or above the center, as at B, chart 27, the punch is raised equal to the thickness of the metal being operated on.

Shop Problems.

In **Canadian Machinery** of May 28, a short letter appears from J. Davies with reference to the milling of square centers. Problems of this nature come generally under the section of the solution of triangles. As it will be impossible in this brief course of lessons to deal with every specific case where shop arithmetic may be applied, suggestions such as this from those who have met puzzling questions in their daily work, will receive due consideration, and if possible be answered by bringing them to the attention of the editor.

SAFETY FIRST IN RIVETING.

As a result of the "Safety First" movement, numerous safety appliance laws are being drafted, among the provisions of which are requirements that riveting hammers embody in their construction devices to prevent the accidental ejection of the rivet set from the nozzle of the hammer. A novel rivet set retainer is that now put out with the "Little David" pneumatic riveter.

The retainer consists of but a single piece of heavy spring steel, closely wound into a spiral form. One end of this spring fits over the outside of the hammer nozzle and hooks over a projection integral with the nozzle. The other end is wound to a smaller diameter. Sets for rivets over 7/8-inch diameter are formed with a coarse thread, and are simply screwed into place. Sets for rivets 7/8-inch diameter and smaller are formed with a shoulder, and are slipped into the retainer while it is detached from the hammer, the shoulder holding it in place. The device positively prevents the rivet set or piston from being driven out, even when the hammer is run free.

Other important improvements have been embodied in the above riveter. There is but a single ground joint handle and barrel, and these parts are securely held together by two bolts, one on either side of the barrel. This construction eliminates the need of a vise in taking the tool apart for inspection, a feature of value to the structural worker, as well as others who are not usually equipped with special facilities for repair work. There are no threaded joints on the barrel. The valve chamber is placed beside and parallel to, instead of in line with the cylinder, obviating all possibility of injury to the valve by the piston. This construction gives a short tool, adding to its usefulness, as it can be used in closer quarters.

"Little David" riveters are manufactured by the Ingersoll-Rand Co., of New York and Montreal, and are made with either outside or inside types of triggers, in five regular sizes adapted for all kinds of riveting work. In addition, there are two sizes of jam riveters, which have an exceptionally short over-all length, making them also peculiarly well adapted for riveting in very cramped quarters.

FOUNDRY AND MACHINE CO. EXHIBITION.

We are advised that the coming Foundry and Machine Co. Exhibition to be held in Chicago during the week of the American Foundrymen's and Allied Associationa' Convention will probably surpass in scope and variety of equipment last year's junction. A large number of reservations have already been made, and several manufacturers have increased their space of a year ago, while the number of exhibitors seems likely to exceed that of any previous occasion.

AMERICAN FOUNDRYMEN'S ASSOCIATION CONVENTION.

The advance program for the annual convention of the American Foundrymen's Association at Chicago, September 7-11, has now been prepared, and will be generally as follows:

Monday, September 7.—Registration at the LaSalle Hotel.

Tuesday, September 8, 10 a.m.—Joint meeting with the American Institute of Metals and Associated Foundry Foremen at the LaSalle Hotel. Formal addresses to be followed by a number of papers on "Safety Work in Foundry Operations."

Tuesday, 2 p.m.—Individual session of the American Foundrymen's Association at the LaSalle Hotel. Papers will be presented on "Foundry Construction and Equipment."

Wednesday, September 9, 10 a.m.—Joint meeting with the American Institute of Metals at the Saddle and Sirloin Club, adjacent to the International Amphitheater, where the Foundry and Machine Exhibition Co. will conduct its big exhibition of foundry equipment and supplies. This session has been termed a "Cost Congress." Paper will be read and addreses delivered on the necessity of obtaining accurate costs in foundry operations. How to make bids for work will be discussed and a report on this all-important subject will be submitted. The cost committee of the American Foundymen's Association will present its annual report, suggesting a revision of the Standard Foundry Cost System and a number of papers will be read on "Efficiency in Foundry Operations."

Wednesday, Noon.—Ladies' luncheon at the Stockyards Inn.

Wednesday, 2 p.m.—Entire session devoted exclusively to the discussion of "Malleable Foundry Practice."

Wednesday Afternoon.—Stockyards inspection.

Wednesday Evening.—Visit to the White City.

Thursday, September 10, 10 a.m.—This session will be devoted to "Steel Foundry Practice," the program being prepared by R. A. Bull, senior vice-president of the American Foundrymen's Association.

Thursday, 2 p.m.—This session will be devoted exclusively to the presentation of papers and the discussion of "Gray Iron Foundry Practice."

Thursday Evening.—Banquet at the LaSalle Hotel, for members only. Speeches will be limited to one or two addresses by speakers of national fame. Banquet for ladies at the LaSalle Hotel.

OFFICERS ELECTED BY ELECTRICIANS.

Canadian Electrical Association. — The Canadian Electrical Association concluded its twenty-fourth annual meeting on June 26. Colonel D. R. Street, Ottawa, was re-elected president, and the other offices were filled as follows.—First vice-president, D. H. McDougall, Toronto; second vice-president, R. M. Wilson, Montreal; third vice-president, Wills Maclachlan, Toronto; honorary secretary, T. S. Young; secretary-treasurer, Alan Sullivan, Toronto. Managing Committee—J. S. Gould, Smith's Falls; G. W. Magalhaos, Toronto; P. T. Davies, Montreal; H. G. Matthews, Quebec; A. E. Dunlop, Pembroke; J. S. Norris, Montreal; Geo. Kidd, Vancouver; Robin Boyle, Niagara Falls; W. G. Angus, Hamilton; W. S. Robertson, Toronto; E. L. Milliken, Sydney; L. W. Pratt, Hamilton; H. R. Mallison, Montreal; H. Hulme, Montreal. The next place of meeting was left to the managing committee to decide.

TURBINE AUTOMOBILES.

The Royal Automobile Club of England has just announced that it will hold a competition next year for internal combustion turbine motors.

A double novelty is here—a motorcar run by a turbine and a turbine worked by internal combustion. It was said years ago that an internal combustion turbine would be possible if only platinum were not the most precious of metals, the idea being that nothing but platinum or some similar practically infusible metal could be used for the rotor blades. The action of the Royal Automobile Club in announcing this competition indicates that substantial propress has been made, for otherwise there would be no reason for such an announcement.

"As a matter of fact," writes W. Whittall, motoring editor of the Illustrated London News, "I am able to say that not only has such progress actually been made, but that there is in existence at the present moment an internal combustion turbine motor which I am told on excellent authority does comply with all the requirements necessary for success. In power output for weight of motor it compares quite favorably with engines of the reciprocating type, while in point of fuel efficiency I am told that it leaves little to be desired."

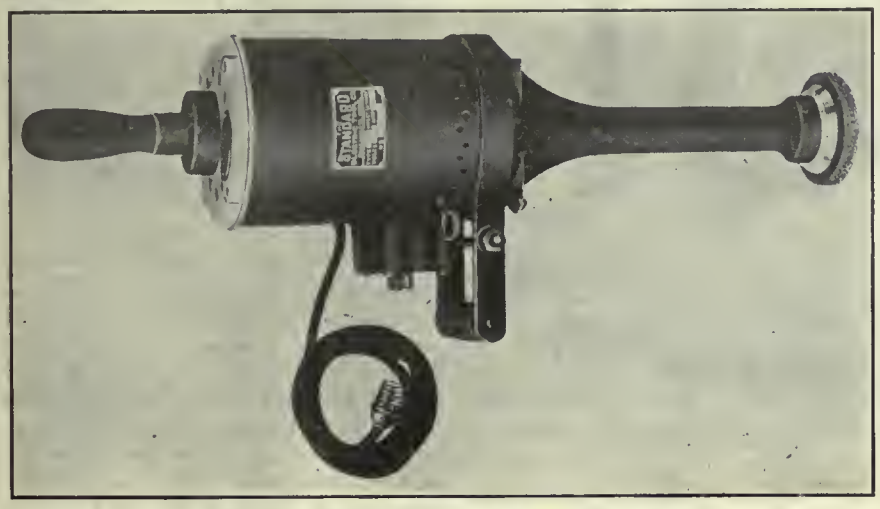
Strassburg, Sask.—The general contract has been awarded to Winnipeg Engineering Co., for the supply of material and construction of a telephone system, at a cost of $6,575 for East Mt. Royal Telephone Co.

PROGRESS IN NEW EQUIPMENT

A Record of New and Improved Machinery and Accessories for the Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

UNIVERSAL PORTABLE ELECTRIC GRINDER.

THE Standard Electric Tool Co. of Cincinnati, Ohio, have placed on the market a new grinder of the aerial type for surfacing rough castings and for buffing. This tool has a universal motor that operates on both alternating and direct current, being interchangeable, with enqual efficiency. It is especially adapted to low frequency circuits such as 25, 30 and 40 cycles.



UNIVERSAL PORTABLE ELECTRIC GRINDER.

The motor is form-wound and impregnated in Bakelite, which method of winding and insulation prevents short circuits, grounds and other troubles incident to high speed apparatus if constructed according to slow speed motor practice. The speed is 6,000 r.p.m. and the tool is fitted with an emery wheel of 4 ins. in diameter, 1 in. face. Ball bearings are employed throughout.

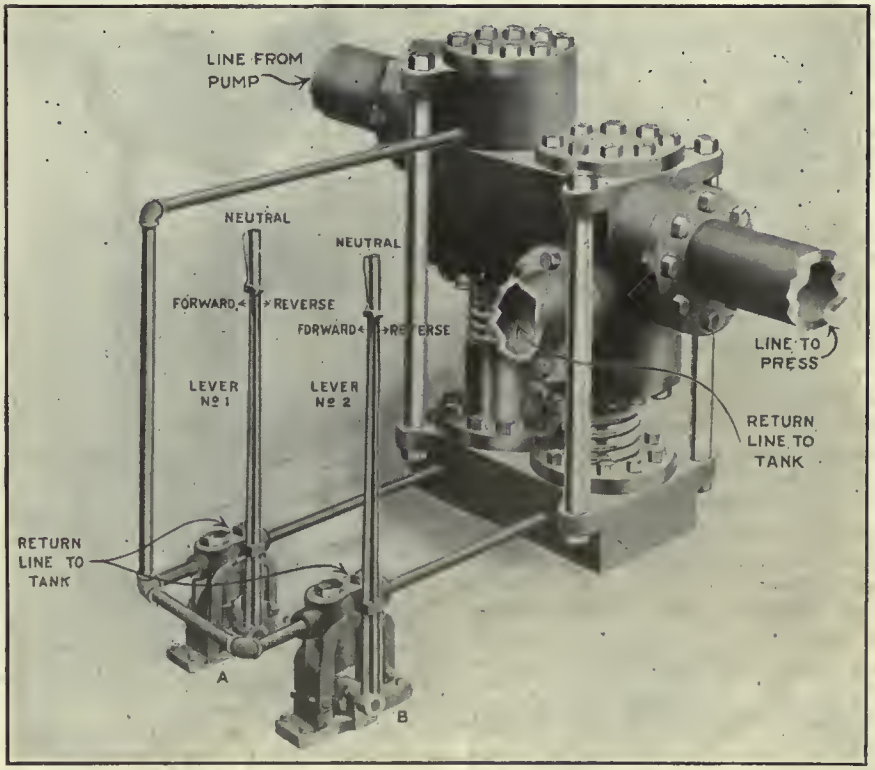
The motor has a capacity of ½-h.p. and claimed to be durable and efficient. It is highly effective on alternating current. The workmanship and material are high grade, and the tool will stand up under the most vigorous continuous service.

PILOT OPERATED HYDRAULIC POPPET OPERATING VALVE.

Those who operate high pressure hydraulic presses requiring a very large volume of water find it difficult to obtain an operating valve which has sufficient internal areas for this service and one which can be easily controlled. It is an easy matter to design a valve with large openings and large valve seat areas, but the difficulty arises in its manipulation. For high pressure, where a large volume of water is required, the Hydraulic Press Mfg. Co., Mount Gilead, Ohio, have designed and are putting upon the market the Hydraulic Three Way Pilot Operated Poppet Operating Valve shown by the accompanying illustration. This valve has a steel body and is designed for a pressure of 5,000 pounds per square inch and upwards. It has double checks and flanged connections. Special gun metal bronze is used in constructing the valve seats and checks, while the operating cylinder, glands and rams are cast of steel.

This type of operating valve is controlled by means of two small pilot valves. These are marked A and B in the illustration and are necessary on account of the large area of the main valve openings. These controlling operating valves need not be located near the main valve as shown in the illustration, but may be located at any point convenient. The main valve may be located under the press next to the cylinder and out of sight and yet be controlled by the pilot valves which are located at any convenient place on the floor. This is a feature often overlooked by operators of hydraulic equipment.

The main valve has three openings and four positions. The first applies the pressure to the press; the second holds the pressure on the press, line and pump; the third holds the pressure on the pump and line and relieves it from the press, while the fourth position relieves the pressure from both the press and pump. The method of obtaining the four positions is described as follows:



PILOT OPERATED HYDRAULIC POPPET OPERATED VALVES.

Position No. 1, lever No. 1 should be forward and lever No. 2 reverse.

Position No. 2, lever No. 1 reverse and lever No. 2 reverse.

Position No. 3, lever No. 1 reverse and lever No. 2 forward.

Position No. 4, lever No. 1 forward and lever No. 2 forward.

Either of these pilot valves used to operate this poppet operated valve may be employed singly to control the operation of an hydraulic press which requires a medium amount of pressure. Each valve has three openings, two checks and three positions. When used singly to control the pressure on a single hydraulic press their operation is described as follows:

The middle position is neutral. With the valve in this position, the pressure is held on the pressure line and the return line from the press is closed. In the forward position, the pressure is applied to the press and the return line is closed. In the reverse position, the opening from the pressure line is closed, the pressure is held on the line, and the press cylinder is open to the return line. This type of pilot valve is suitable for use where the pressure is to be held on the line, but not where the pump is to run free while the pressure is held on the press.

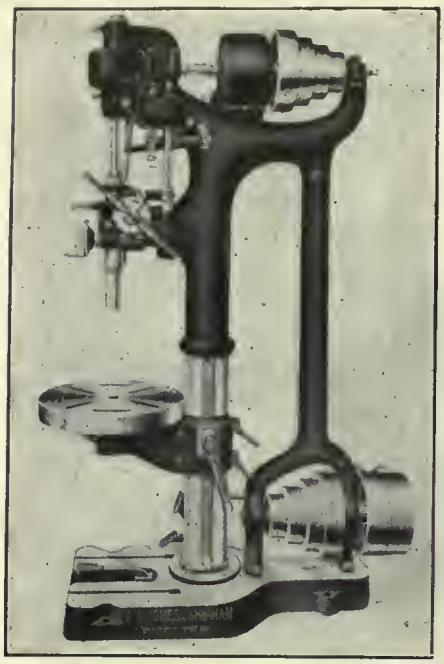
NEW DESIGN VERTICAL DRILLING MACHINES.

One might be almost justified in concluding that in multiplicity of number and more or less variety in design it were somewhat hard to produce anything of really outstanding merit in drilling machines, yet in spite of any tendency that way, there is development and progress being recorded in this important mechanism and in the "New Century" 22 and 25-inch vertical drilling machines which form the subject of this article there are quite a number of features worthy of attention.

It were superfluous, perhaps, to remark that high grade workmanship, weight and power for their particular duty are basic factors in these products. The drilling capacities are such also as to fulfil the high speed requirements of modern manufacturing shops. Among several improvements may be noted the following:—

The entire column and arms are in one casting, and the machined portion of the column is ground to within the finest limits of accuracy. The bearings are gun metal ring-oiling, while the back gear pinions and clutches operating same, and the driving bevel pinions are steel.

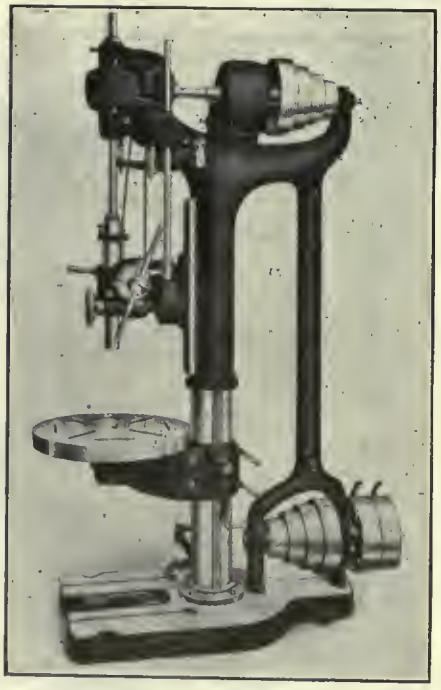
The automatic feed has four changes, operated by a lever, with positive stop to each position of feed. The drive is positive, by high grade roller chain. All feed gears are of steel, and hardened where necessary. The spindle is made from high carbon steel, accurately ground fitted with high grade ball thrust and adjustable lock nuts. The quill is accurately ground and graduated, and in-



NEW CENTURY 22-INCH FIXED HEAD DRILLING MACHINE.

ternally lubricated by means of a double spiral groove, and fitted with steel rack which is inserted in a miled groove.

The new patented cross axle feed mechanism for engaging and disengaging



NEW CENTURY 25-INCH SLIDING HEAD DRILLING MACHINE.

the automatic and hand worm feeds, while practically instantaneous and absolutely positive, enables a fixed worm bracket being used, the worm wheel being always in mesh, the mere fraction of a turn of the knurled boss on the worm wheel throwing the feed instantly in or out of action. The top driving shaft has forced internal lubrication to the cone pulley and back gears.

The table is of large diameter, heavy and well-ribbed, while the table bracket is of improved and massive design, the rack for raising and lowering same being of steel.

The tapping reverse control rod is carried inside the column, while the pedal is fixed in the center of base plate and is detachable. The following examples of normal drilling on these machines under ordinary workshop conditions and without special preparation are worthy of notice:

Diameter of drill	1 in.	1¼ in.	1½ in.
Revs. per minute	400	250	250
Revs. per 1 in. feed	50	50	74
Penetration speed	8 in.	5 in.	3½ in.
Cubic inches of metal removed per minute.	6¼ in.	6 in.	6 in.

Referring particularly to the 22 ins., drill with fixed head, the distance from center of spindle to column is 11½ ins.; vertical movement of spindle, 12 ins.; spindle speeds with back gear, 16-26-40-64; spindle speeds without back gear, 100-160-250-400; spindle revolutions per inch of automatic feed, 51-74-121-174; diameter of table, 21 ins.; vertical movement of table, 20 ins.; size of base, 41¾ ins., by 20 ins.; height from floor to top of cone pulley, 84 ins.; approximate net weight, 1,200 lbs. The vertical adjustment of sliding head is 15 inches.

In the case of the 25 ins. drill, the distance from center of spindle to column is 12⅝ ins.; the vertical movement of spindle, 12 ins.; spindle speeds with back gear, 16-26-40-64; spindle speeds without back gear, 100-160-250-400; spindle revolutions per inch of automatic feed, 51-74-121-174; diameter of table, 24 ins.; vertical movement of table, 20 ins.; base 46½ ins., by 24½ ins.; height to top of cone pulley, 84 ins.; approximate net weight, 1,300 lbs. The vertical movement of sliding head is 18 inches.

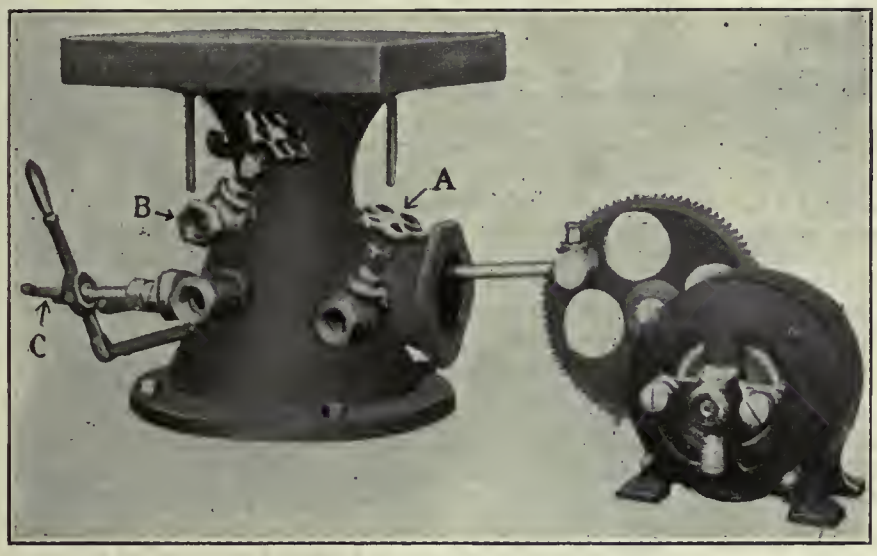
A. A. Jones & Shipman, Ltd., New Century Works, Leicester, England, are the builders of the above machines.

NEW JOLT RAMMER.

The illustrations and description refer to a new jolt rammer invented by Wm. T. Krause, 3623 N. Ashlands Ave. Chicago. The novel feature of the machine is the direct compression of the air necessary for operation through the medium of an electric motor conected to the apparatus.

Air at atmospheric pressure is taken into the horizontal cylinder through the intake valve A, and is compressed sufficiently to raise the plunger and table in

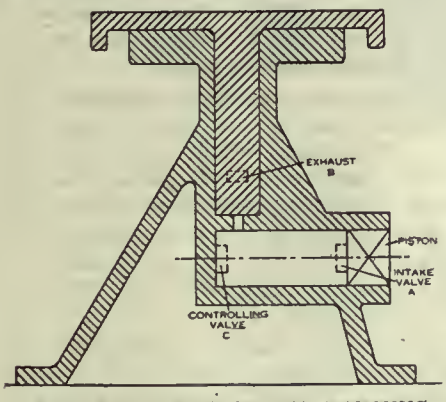
the vertical cylinder until the former uncovers the exhaust port B, whence the compressed air rushes out and drops the plunger and table. The horizontal and vertical cylinders are connected by a small air port. The idea is to keep the motor running constantly and so control the operation of the machine by opening and closing the quick opening gate valve C; in this manner doing away with the



NEW JOLT RAMMER.

use of a clutch. The photograph shows the valve C open. By substituting a three-way valve for the valve C, it is possible to compress enough air while the machine is not jolting to run the vibrator and blow gun, also to compress enough air in a tank to raise the plunger and table for pattern drawing.

The claims made on behalf of the apparatus are that it is simple, valveless, camless, clutchless, springless, and can, therefore, not get out of order. A high efficiency is also claimed.



SECTIONAL VIEW OF JAR-RAMMING MACHINE.

The photograph shows the machine with the gear case removed and without the piping. The exhaust is connected to the gear case, thereby using the exhaust air which contains a certain amount of oil to lubricate the moving parts and at the same time create a very low air pressure in the gear case which will leak out through the joints of same and blow away such sand as may tend to work its way into it.

RAILWAY CONSTRUCTION.

Carloads of steel for tracks on the C. N. R. route north and west of Kamloops are commencing to arrive at Kamloops. Of the first consignment of 82 cars more than 8,000 tons, 25 carloads, were received last week and other large shipments are en route. Tracklaying is to be proceeded with at once. Forty-five thousand tons of rails have been ordered by the C. N. P. R. for British Columbia lines. Bridge building near Lytton is being rushed so that rails may be laid from the western end of the Port Mann-Kamloops section as well as from the eastern end.

Track laying on the Coalmont section of the V. V. & E. line through the Similkameen is to be started early in July, states J. H. Kennedy, assistant to the chief engineer of the line, who has recently returned from a trip over the Hope Mountain route in company with A. H. Rogeland, chief engineer of the G N. R. This portion of the road is to be used jointly by the Kettle Valley Railway and the V. V. & E., in accordance with an arrangement between the two companies.

The V. V. & E. portion of the line between Coalmont and Otter Summit will be ready for traffic this summer. Pending the completion of the main route from Coquehalla Summit to Hope, the C. P. R. will operate trains via the Nicola Valley branch and Merritt, around by the Kettle Valley line into the Similkameen and the Okanagan. Rapid progress is being made with the portions of the Kettle Valley route east of Coalmont and in the Okanagan.

In order that structural work may be started on the bridge across the Fraser near Hope, grading is being done on the connecting link between the C. P. R. and the bridge on the north side. The sub-structure of the bridge is finished, and as soon as the mile and a half section of track which will be required to furnish the connection has been built, steel for the bridge will be transported. Rails for the Hope-Coquehalla joint section will be shipped via the C. P. R., and over the new bridge to Hope.

CANADA IRON CORPORATION.

The bondholders of the Canada Iron Corporation, at a meeting held in Montreal on July 2, formally assented to the reorganization plan submitted by the committee appointed for the purpose some months ago.

The next step in the reorganization proceedings will be a meeting of the general creditors of the corporation, to be held at the Courthouse, Montreal, on July 15. If the creditors give their consent to the plan, arrangements will be made at once to put it into effect. Failure to obtain this consent of the creditors would upset all the work of the bondholders' committee and necessitate the devising of some new plan of salvage.

The resolution adopted by the bondholders to-day provides for the cancelling of the existing trust deed, and the acceptance by the first mortage bondholders of 6 per cent. debenture stock, to be known as "B debenture stock," on a new company, the exchange to be on the basis of par for par. Ahead of this security will be "A debenture stock," of an authorized amount of $200,000, of which not less than $120,000, and not more than $140,000, will be subscribed at 95 to provide the necessary cash working capital. Preferred and common shares will also be created, the amounts to be determined after negotiation with the second bondholders, holders of secured notes, and other creditors of the old corporation.

The old preference and common stock will be wiped out, but shareholders who subscribe to the A debenture issue will be given a bonus of common stock, which, in the event of the drastic reorganization proving, as is likely, a sound and successful enterprise, will offer some chance of the old shareholders recouping their issues, in part at least.

Harriston, Ont.—The Harriston Casket Co. has recently added to the equipment of their factory a number of new machines of the most recent construction, which will largely increase the capacity of the concern.

ERRONEOUS USE OF SYSTEMS.

OF all the unfortunate words in our language, and be it said, the still more unfortunate results of what it is intended to stand for or accomplish, that known as **system** seems to us—if we might use a slang expression—to be the limit.

In the past two and present issues of **Canadian Machinery**, three different types of management have been featured—the rule-of-thumb, the systematic, and the efficient. It is in no way necessary here to take up in detail the various points dealt with throughout the series, although subsequent reference may be made to some of these in our columns. The glaring misconception of business ideals is clearly indicated in the various articles, and no one who has read them can have failed to note that systems figure largely therein.

Nothing in this world was ever accomplished by adherence to system, and nothing ever will be, unless the turning of human beings into automatons be excepted. System, or keeping men in the rut, will neither breed nor yet will it develop intelligence. For a very good reason. Intelligence is unnecessary.

It seems to be completely overlooked that what are known as systems are simply means to be utilized according as they suit our purpose or work into our plans to attain an end or ideal in the most advantageous way possible. We may go from Toronto to Port Arthur at the head of the lakes by the all-rail route or by the rail and water route. In the former case, we avail ourselves of the Canadian Pacific Railroad system. In the latter case, we go over the Grand Trunk Railway System to Sarnia, and from thence by boat to Port Arthur. Think you that it is a matter of indifference, the choice you are called upon to make, and isn't there a considerable satisfaction in knowing that you are not tied up to either, which you would be if only one of the two existed, or if you were bidden go by either one without choice. The privilege of choice is sweet; in other words, you are not a little flattered at being called upon to exercise your own initiative, and whether the particular decision made be after all the most advantageous, you gain an experience which will be later valuable under like or more momentous circumstances.

Human beings are entirely distinct from street cars or railroad trains. The latter run on rails; yes, on schedule sometimes, but of themselves they achieve nothing. Unfortunately, too many of us run also on rails or their equivalent. We are scheduled to accomplish something, as in the case of the train, in a given time, and maybe are uniformly successful. We seldom, however, make an effort to get ahead of schedule, thereby failing in the duty we owe to ourselves in showing some initiative and in getting beyond system or out of the rut. Not only so, but we, by failing to note that some others in, or some section of our organization are well ahead, prevent a general forward movement, some record accomplishment, it may be, in product output, and cause valuable time to be lost through our dogged adherence to system.

It is a hopeful sign to see the expression **systematic business management** disappear, and its replacement by the word **management** only. The highest efficiency, or, for that matter, any efficiency worthy the name, cannot be got by system as generally understood. Systems are mere subsidiaries or routes to be utilized in whole, in part, or not at all, in the carrying out of our plans, and accomplishment and achievement records go to show that they figured in low degree in most cases.

To have to adhere to a definite system is always expensive, like its prototype in the case of only one railroad to a particular destination. Competition in the latter case usually cheapens transportation (combines excepted), and in business affairs where a definite ideal (that of the highest efficiency in output is concerned), the individual or collective competition to achieve something higher than the system, something beyond grovelling in the rut or being a mummified automaton, will, as in the case of competitive transportation routes, bring its reward. It will, however, be more meritorious, because of its having raised a higher type of men.

INDUSTRIAL NOTABILITIES--No. 42

WILLIAM HORSLEY ROWLEY, J.P., president the E. B. Eddy Co., match, paper and woodenware manufacturers, Hull, Que., was born at Yarmouth, N.S., March 21, 1851, son of Lieut.-Col. J. W. H. and Ann Norman (Farish) Rowley, daughter of Henry Greggs Farish, M.D. He was educated in Yarmouth, graduating later from the Royal Military School, Halifax, N.S., and receiving there his lieutenant's commission.

Mr. Rowley started his business career in the service of the Bank of Yarmouth about 1867, and a few years later he was in mercantile employment in St. John, N.B. He was in the service of the Merchants Bank of Canada from 1871 to 1886, being manager of the Ottawa Branch from 1880. He organized and was a charter member of the E. B. Eddy Co., occupying the position of Secretary-Treasurer from 1886 to 1906, since which last date he has been its president. He is a past-president of the Canadian Manufacturers' Association, and was a delegate to the Commercial Congress of the Empire, in Sydney, Australia, in 1909.

WILLIAM HORSLEY ROWLEY, J.P.

He is a director of the Eastern Canada Manufacturers' Mutual Fire Insurance Co.; director Eastern Canada Exhibition Association; director Ashbury College; director Perley Home for Incurables; was president, Canadian Immigration Guild during 1910; and is an active member and officer of Christ Church Cathedral, Ottawa. Mr. Rowley has been twice married, one son born in 1912 being the sole surviving issue.

A Conservative in politics and Anglican in religion, a member of the Rideau, Laurentian, Royal Ottawa Golf, Ottawa Athletic, Ottawa Canoe, Ottawa Hunt, Victoria Yacht, Ottawa Country Clubs, Ottawa; the Mount Royal, Montreal; and the York, Albany, and National, Toronto, Mr. Rowley finds his outdoor recreations in angling, bowling and riding. His residence is Stadacona Hall, Worfield, Ottawa.

A first-class business man, and controlling the largest industry of its kind in the British Empire, says public opinion.—Photo, courtesy the International Press.

The General Market Conditions and Tendencies

This section sets forth the views and observations of men qualified to judge the outlook and with whom we are in close touch through provincial correspondents.

Montreal, Que., July 6, 1914.—There has apparently been little improvement in business, and in most instances the supply men do not expect much change from present conditions for at least a month or two. It is generally anticipated that the fall will see a resumption of activity, and although it is not thought it will be in the nature of a boom, it seems reasonable to assume that after such a long period of quietness there certainly should be a resumption approaching normal.

As has already been stated, there is a good deal of building being carried on locally, and the city government is spending considerable money in street improvements and public works generally. The new plant of the Canadian Vickers' Co., in Maisonneuve, is rapidly nearing completion, and this should add to the general activity when it is in full operation.

Metals.

There has been a slight improvement in the situation as regards metals, though most of the markets are still rather quiet and weak. Spelter was marked up 10 cents, and tin is quoted 50 cents above last week's figures. Sterling quotations to-day are as follows: Tin, £146; copper, £62 10s; lead, £19 5s; spelter, £21 10s; pig iron, £51 3s. There is still a tendency on the part of purchasing agents to buy only sufficient supplies for immediate needs; business, therefore, is not very active.

Toronto, Ont., July 7., 1914—Business is still very dull, and seems likely to remain in this condition in the near future. The crop reports, which continue to be favorable, are helping to keep commercial interests from becoming too pessimistic, and are tending to instill a more hopeful spirit into the situation. Although the general outlook is more promising, the volume of business being done cannot be said to be altogether satisfactory. Manufacturers are in many cases running their plants considerably below capacity, and consequently buying less material, this being in proportion to the output.

A spirit of caution is general, and is justified to a large extent on account of the prevailing conditions. Considering the severity of the depression, it is encouraging to note how comparatively few concerns have gone into liquidation. This tends to show that generally speaking our industries are established on a sound basis, and that a slowing down of business cannot materially affect the economic position of the country.

Steel Market.

The steel market continues dull, with little business being done, and that only at low prices. The rumors which have been circulated lately regarding the proposed steel plant at Ojibway, near Windsor, Ont., have received their quietus. President E. H. Gary, of the United Steel Corporation, in a speech delivered recently in New York, states that the finance committee of that corporation would hesitate to approve of any appropriation at the present time for establishing a steel plant in Canada.

The Algoma Steel Corporation recently booked an order for 3,000 tons of rails for an Ohio railroad in competition with United States mills. The Toronto Board of Control have approved of specifications for the proposed Bloor street viaduct, and tenders will probably be called shortly. It is likely that it will be a steel structure, in which case a large amount of material will be required.

Reports from the United States indicate that the prospects for July steel trade are relatively better than is usual for this month, when business usnally falls off. It is anticipated that production will be substantially as large as June. Steel prices are stationary, and a further decline is not expected.

Pig Iron.

There is no change this week in the pig iron situation, and prices remain at

the same low level. The Dominion Steel Corporation has decided that in view of the recent heavy sales to Australian and Canadian railways, they will be unable to accept any additional orders for pig iron for delivery to the United States, beyond the 25,000 tons already contracted for.

Machine Tools.

Dealers in machine tools report trade as being very quiet, with little business offering. Consumers are still holding back until conditions improve, which can hardly be expected until the fall at least.

Metals.

Although the metal markets are quiet, a better tone prevails, and rather more business is offering. Prices keep at about the same level, with the exception of tin, which is stronger, having advanced 3 cents a pound.

Trade Gossip

Locomotive Order.—The Canadian Pacific Railroad has ordered 10 locomotives from the Montreal Locomotive Works.

Jonathan Birch & Co., of London, Ont., has been awarded a contract for cast iron pipe, 4 in. to 12 in. diameter, by the city of St. John, N.B.

The Canadian Westinghouse Co., Hamilton, has been given the contract for the installation of two 3-phase self-starting synchronous condensers at $52,900, for the City of Winnipeg.

The Turbine Equipment Co., Toronto, have sold to the Can. Westinghouse Co., one De Laval 6-inch, two-stage turbine pump with a capacity of 700 gallons per minute against a head of 300 feet.

The Marshall-Mitchell Hardware Co. has been awarded the contract for the heating and ventilation of an addition to the Alexandra school, Medicine Hat, Alta., at a cost of $20,789.82.

Poole & Emery, of Moose Jaw, Sask., have been awarded the general contract for a $75,000 office building for the Saskatchewan Co-operative Elevator Co. Architects, Storey & Van Egmond, 1013 McCallum Hill Bldg.

Pressed Steel Car Plant in England.—Charles T. Schoen, formerly of Pittsburgh, the pressed steel car inventor and manufacturer, announces that he is planning to establish a plant at Leeds, England, for the manufacture of this commodity.

Dominion Iron & Steel Co.—Advice from Sydney, N.S., state that at a meeting of the directors of the Dominion Iron & Steel Co., it was decided that in view of their recent heavy sales of rails to Australia and Canadian railways, the company would be unable to make any additional further shipments of pig iron to the United States. About 25,000 tons has been shipped so far.

Escher, Wyss & Co., Montreal, have been awarded a contract by the town of Joliette, Que., for the supply of one 200-h.p. Francis turbine and two belt-driven centrifugal pumps, each of two million gallons capacity, working against 62 pounds pressure when single and in parallel, and 130 pounds pressure when working in series. Surveyer & Frigon, of Montreal, are the consulting engineers.

To Re-open Plants.—Word has been received from New Glasgow, N.S., that the plant of the Eastern Car Co., which has been closed down for some time, is to be re-opened and that men are being engaged to report for work at once. It is stated that the company has received a substantial order from the Intercolonial Railway for box cars, which will keep the works busy for some time. The Eastern Car Co. is the relatively new formed subsidiary of Nova Scotia Steel & Coal Co.

Hon William R. Ross, Minister of Lands, for British Columbia, has received a letter from the Dominion Creosoting Co., Ltd., of South Vancouver, stating that they have received an order for 160,000 creosoted railway sleepers from the Bengal & Northwestern Railway Co., of India, and expressing thanks to the Forest Branch of the Department of Lands, for its efforts in interesting the Indian Railway Co. in British Columbia lumber.

The Steinle Turret Machine Co., Madison, Wis., are making new arrangements for the sale of their turret lathes, as their former selling connections with Manning, Maxwell and Moore, Inc., have been discontinued. They have appointed Hill, Clarke & Co., 156 Oliver St., Boston, Mass., as their exclusive agents in the New England States and Laughlin-Barney Machy. Co., Union Bank Bldg., Pittsburgh, Pa., have been awarded the exclusive right for the sale of their product in Western Pennsylvania.

Doubling Ford Plant.—The Ford Motor Co. will double its Detroit plant this fall, making it the largest manufacturing concern in the United States, and probably in the world. Seven new buildings and a power house are to be erected, at a cost of about $5,000,000. The buildings will each be 900 feet long by 60 feet wide and six stories high. The power house will be 240 feet long, 150 wide and 85 feet high, and will house the largest gasoline engine in the world, driving motors that will produce 80,000 horse-power. The company plans, with these increased facilities, to double its 1914 output next year. This means that when the factory is running full, about 40,000 men will be employed.

Regina Engineering Society. — The Regina Engineering Society executive for the present year is as follows: — President, H. S. Carpenter, Board of Highway Commissioners, Saskatchewan Government, Regina; first vice-president, L. A. Thornton, city commissioner, Regina; second vice-president, R. O. Wynne-Roberts, consulting engineer, City Hall, Regina; secretary, J. M. Mackay, superintendent of waterworks, Regina; treasurer, R. N. Blackburn, chief boiler inspector, Saskatchewan Government, Regina.

Hall Engineering Works.—A strong bid was made recently for the purchase of the Hall Engineering Works, Montreal, by one of the largest British shipbuilding firms, but the offer through substantial was not sufficient to induce Mr. Thomas Hall, the owner, to part with the property which is the largest privately owned ship repairing plant in the Dominion. The works situated on Jurors street were established some ten years ago by Mr. Hall, who was formerly superintendent engineer for both the Canadian Pacific and Elder Dempster Companies in London, Eng. They have grown to a considerable extent since then, being now valued at a quarter of a million. This businesslike plant handles most of the large marine repair work at the port of Montreal, as well as a good deal of land work.

Niles-Bement-Pond Co. Achievement —The Chilean Parliament last year appropriated $30,000 to be given as prizes to enable them to secure the best designs for a general railroad shop to have capacity to take care of 500 to 600 locomotives, 500 passenger cars and 6,000 freight cars; $20,000 to be for the first prize, and $10,000 for the second. The Niles-Bement-Pond Co. submitted plans of what they considered to be the latest practice as exemplified in American railroading. Forty sheets of drawings were submitted showing the ground plan and elevation of every building; also a plan of the yard with tracks, yard cranes, paving, etc., complete; also plans of the wiring, power distribution, etc.; also plans of a central power station and its equipments. Two complete plans of machine and erecting shops were submitted, one on the transverse pattern and one longitudinal. The specifications were officially received on May 1, and there were competitors from various parts of the world. The awards were made in the first week of June, with the result that the Niles Co. were given the first prize, the second prize going to a combination Belgian and English concern. It is expected that these shops will cost about $3,000,000.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News.

Engineering

Sarnia, Ont.—The Mueller Mfg. Co. will probably build an iron foundry.

London, Ont.—The McClary Mfg. Co. are making an extension to their factory at a cost of $15,000.

Rossland, B.C.—The West Kootenay Power & Light Co. contemplate the construction of a new lighting system.

St. John's, Que.—The Canadian Hart Accumulator Co. will shortly begin the construction of their new factory. Architect, S. Warwick, Montreal.

St. Vital, Man.—Construction will commence shortly on the new engineering building for the University of Manitoba. The cost is estimated at $250,000.

Toronto, Ont.—The Temiskaming & Northern Ontario Railway, will install heating systems at their new stations. A. J. MacGee, secretary-treasurer, Toronto.

Bolton, Ont.—Dick's Foundry was totally destroyed by fire recently. The damage is estimated at $20,000, against which there is only about $5,000 insurance.

Berlin, Ont.—The Regal Motor Car Co. of Detroit, Mich., are building a factory here. It is expected that it will be completed about August 1. Henry Nyberg will be in charge.

Guelph, Ont.—The Light, Heat and Power commission has confirmed the building of the ammonia tanks at the gas works. It is expected that this work will cost about $2,700.

Toronto, Ont.—Commissioner Harris has recommended that the National Equipment Co. be granted permission to erect a 400-gallon gasoline tank under the sidewalk at 1136-1142 College St.

Toronto, Ont.—A new 4-inch. centrifugal pump costing $461 has been purchased for the main sewage disposal works at Morley avenue. This was the lowest tender, and was awarded to a Buffalo firm.

Guelph, Ont.—Two applications have been received from local manufacturing concerns asking that a fixed assessment be granted. After careful consideration the committee decided to recommend that Tolton Bros. be granted a fixed assessment of $4,000 per year for a period of ten years, exclusive of school and local improvement taxes, and that Crowe's Iron Works be given a fixed taxation of $10,000 for the same length of time and under the same conditions.

Toronto, Ont.—The Berg Machinery Mfg. Co. has assigned to J. P. Langley, and the creditors of the concern will meet in Mr. Langley's offices in the McKinnon Building, on Friday, July 10. The company was engaged in the manufacture of brick machinery, engines and boilers and general machinery. Anton Berg is president, John Berg, vice-president, and Severn Berg, superintendent of the works which are situated at the corner of Bathurst and Niagara streets.

EQUIPMENT REQUIRED.

The Victoria (Australia) Railway Commissioners will receive tenders at Melbourne, for the supply of:

3 50-ton overhead electric travelers.

30-ton overhead electric traveler.

3 10-ton overhead electric travelers.

up to August 26, 1914, and up to September 2, 1914, for the supply of:

24 sets air-cooled petrol engine sets for railway inspection cars and,

1 horizonal plain milling machine with vertical milling attachment and accessories.

Mails from San Francisco on August 4, and from Vancouver on August 5, will deliver the above tenders at Melbourne against the respective closing dates.

Full particulars as to specifications, etc., may be secured from the Department of Trade and Commerce, Ottawa.

Victoria, B.C.—A date has now been set, of which notice is given by advertisement, for the meeting of the various bodies which are urging the development of the iron ore resources of Vancouver Island. Representatives of the city council, the board of trade, the real estate exchange, the development association and the manufacturers' association will meet to talk over the best way of inducing operation of the deposits of magnetite around Gordon river, Barkley Sound, and elsewhere in the vicinity of Victoria. The Board of Trade is collecting data on the subject.

New Westminster, B.C.—Negotiations have been practically completed for the disposal of the property of the Morrison Nail & Wire Works on Lulu Island, the company having decided to re-open the plant in New Westminster. Through Industrial Commissioner Darling, a site is being arranged where suitable trackage facilities will be available. It is expected that the plant will be in full operation within thirty days. According to Mr. Darling, it is the intention of the company not to confine business to the manufacture of wire and nails but to enlarge its scope along other lines, including staples and fencing.

New Westminster.—On most farms in the Fraser Valley are to be found small workshops where simple repairs to farm implements and vehicles are undertaken. In these shops there are usually a workbench, to which is fitted a vise, and a number of hand tools. Frequently one finds a forge and anvil, but in the farm of R. A. Anderson, on the Jackman road, Aldergrove, there is a comparatively complete machine shop in which is now being built a small steam engine to be used for farm work. Mr. Anderson's shop is equipped with forge, anvil, drilling machine and band saw, and above the work-benches are cabinets filled with steel, iron and wood worker's tools.

Electrical

Chatham, Ont.—The council will probably extend the electric lighting system.

Kincardine, Ont.—The lighting by-law was defeated by 141 votes on June 29. The proposal involved expenditure on a plan to put in an incandescent lighting system.

Montreal, Que.—The contracts will be let shortly for the electrical work in the new boiler house of the Toilet Laundry Co. A. F. Byers & Co., general contractors.

Hamilton, Ont.—An important event in the history of the city took place on July 1, when Sir Adam Beck turned on the hydro-electric street lights. The Cataract Co. has had this contract for fifteen years. Under the new system the cost of lighting the streets has been increased to $88.000, but it is claimed that the city will be much better lighted.

Blenheim, Ont.—At a representative meeting held here on June 30, steps were taken to have the Hydro-electric Power Commission of Ontario report upon a hydro-radial railway from St. Thomas to Amherstburg, to serve the district lying along the north shore of Lake Erie. A permanent organization was formed, with Mayor Little of Blenheim as President.

St. Catharines, Ont.—Estimates have been prepared for the laying of an ornamental, underground lighting system for the Hydro-Electric Commission as follows: 105 single light standards with 1,000 candle-power lamps, approximate cost $11,304; 61 single light standards with 100 watt lamps, approximate cost $6,093. Chairman Commission, J. S. Campbell.

General Industrial

Ottawa, Ont.—Fire recently destroyed the bakery owned by E. Renaud.

Richmond, Que.—The Boston Last Co. are making extensions to their factory.

London, Ont.—The Forest City Glass Co. will make an extension to their factory.

London, Ont.—The A. A. Langford Co. will build a stationery factory to cost $35,000.

Hamilton, Ont.—L. O. Buist will probably make considerable extensions to his ice cream factory.

Brantford, Ont.—The Canada Glue Co. will build a factory here. P. Kreisman is general manager.

London, Ont.—The London Free Press Printing Co. will make an addition to their plant. J. M. Moore, architect, London.

Langham, Sask.—Fire destroyed Peter Wiebe's flour mill and the National Elevator here, recently. Loss $40,000, insurance about $5,000.

New Westminster, B.C.—The directors of the Pacific Chocolate Factory, which was destroyed by fire recently, state that the loss is estimated at about $35,000. The plant will be rebuilt.

Regina, Sask.—Application has been made to the city council for the city to erect a $15,000 broom factory and sell to the Western Broom Co. on easy terms. N. R. Darrach, Western Trust Bldg., is the architect.

Bathurst, N.B.—The construction of the new pulp mill at this place has been started and workmen are now busy on the foundations. A much larger force of men is soon to be put to work and the buildings will be completed as soon as possible.

Highland, Alta.—The Farmers' Co-operative Elevator Co. has the material on the ground for their new elevator. This makes three elevators for Highland, and present indications are that every one of them will be taxed to their utmost capacity to hold the grain this fall.

Toronto, Ont—A $90,000 cigar factory will be erected by Andrew Wilson & Co., at 14 and 16 Front street west. The permit was issued last Friday by the City Architect's Department. The factory will be four storeys high and will be constructed of steel and brick.

Calgary, Alta.—Twelve hundred miners have been thrown out of work and the town of Hosmer, not far from Fernie, B.C., is about to be abandoned by its population owing to the fact that the coal mines at that point, owned and operated by the C. P. R. have been shut down for good. The work of dismantling the machinery is well under way.

Winnipeg, Man.—Damage to the extent of approximately $2,500 was caused by fire on June 26, at the premises of the Alaska Bedding Co., Sutherland street. The fire started in the japanning room, and was caused by the spilling of some flaming japan from a pail in which it was being carried. The damage is covered by insurance.

Montreal, Que.—It is estimated that 13,000,000 bushels of American grain have been received in the Montreal elevators since the opening of navigation this year. This is much in excess of previous consignments received from the States for any corresponding period, and is considered to be a factor in the present grain congestion at the Montreal elevators.

Rossland, B.C.—J. S. Deschamps, lumberman of Rossland, and former mayor, has announced that he will build a 40,000 capacity mill, employing about sixty men, in the city of Nelson. He has negotiated for a site once used by the Yale-Columbia Lumber Co., which burned out, and also for three million feet of logs at Nelson, through W. A. Anstie, general manager of the company.

Tillsonburg, Ont.—Following the passing of the by-law permitting the sale of the mortgage on the property of the Dominion Linen mills to the new company promoted by Ferguson and Sanson, the promoters promise that the mills will be in operation in a very short time after the passing of the by-law. There is a provision also, giving a fixed assessment for a period of years to the new company.

Medicine Hat, Alta.—The Hedley Shaw Milling Co., a subsidiary of the Maple Leaf Milling Co., has been formed to take over the contracts and business of the Maple Leaf Co. at Medicine Hat. The Hedley Shaw Co. has an authorized capital of $1,000,000 and an authorized bond issue of $250,000. Of the latter $150,000 has been sold to a syndicate composed of the principal interests in the Maple Leaf Co.

Saskatoon, Sask.—At a meeting of leading business men held in the Board of Trade office recently, a proposition was considered which, if it can be carried through, will mean the establishment of a new and desirable industry in Saskatoon. It concerns a firm already established in business here which, if the necessary backing can be secured, is prepared to branch out in a line of manufacturing not at present undertaken.

Regina, Sask.—A brick plant with a capacity of 40,000 bricks per day will be erected here in the near future, if the experiments being carried out by Dr. Andrews are successful. Dr. Andrews claims to have found a cheap method of converting Regina clay into the very best quality of brick, and the samples he has displayed fully justify his statements. R. E. A. Leach is looking after the financing of the company and is receiving excellent support.

New Westminster, B.C.—The Nanaimo Cannery Co., which operated a plant near the Brechin Road up to last season, has now been reorganized and will henceforth be known under the firm title of Broder & Lucier. The new proprietors have had several years' experience in the cannery business on the Fraser River, and speak very hopefully of the prospects of the industry, in this district, which they believe to promise a brighter future than the Mainland.

Winnipeg, Man.—The Watkins Medical Co., will erect a three-storey reinforced concrete warehouse and factory at the Annabella street subway to cost $95,000. Operations commence at once, the Haglin Stahr Co. being the contractors. The building will be 85 feet wide, 95 feet high, and though three-storeys in height at first, is designed to carry five additional ones. It will be completed by December 1. The head office of the firm is in Winona, and the architects are Woodman & Carey, of Winnipeg.

Municipal

Berlin, Ont.—A number of citizens are protesting against the proposal to establish a gas plant in a certain section of the city.

Elmira, Ont.—A by-law will be voted on by the ratepayers on July 14, to authorize the raising of $2,000 for the waterworks system.

Moncton, N.B.—The council are considering the question of installing a municipal power plant.

Trenton, Ont.—Work on sewer extension has commenced under the direction of the engineer. About $25,000 is to be expended on the improved system.

Berlin, Ont.—Ratepayers of Waterloo on July 4, carried the Doering Trunk Co. by-law for the town to grant a loan of $15,000 for a number of years. The vote in favor of the by-law was 373, against 126.

Castor, Alta.—The town council contemplate purchasing (1)—6 in. piping; (2)—12,000 gallon tank; (3)—suitable pumping engine, for the purposes of fire equipment. Mayor Geo. M. Dillon, secretary-treasurer, L. B. Brown.

Calgary, Alta.—Three by-laws were carried by the ratepayers recently by large majorities. They included $360,000 for exhibition buildings, $300,000 for electric light extensions and $90,000 for the street railway. The park improvements by-law was defeated.

Mimico, Ont.—At a meeting held here on July 2, a Board of Trade was formed and officers were elected as follows: president, James Gormaly; first vice-president, E. Coxhead; second vice-president, J. H. Doughty; treasurer, W. W. Burgess, secretary, B. W. Ballard. A council of twelve members was also elected.

Fredericton, N.B.—The fire committee of the city council met recently to consider the question of repairs to the fire alarm system. The battery room, which is now situated in the tower of the city hall, will eventually be removed to the new central station. A storage battery will be installed, instead of the wet cell system now in use.

Guelph, Ont.—On account of the presence of so many factories in the lower end of St. Patrick's Ward, and their demand for light and power, the erection of another high tension transforming station, similar to the one on Huskisson street, has been decided upon. It will cost in the neighborhood of $4,000, and will be proceeded with at once.

Stratford, Ont.—At a special meeting of the Council in committee last Thursday, Chief Kappele was instructed to ask tenders for one steam fire engine, one city service ladder truck, one horse-drawn combination chemical and hose wagon. In connection with the latter, tenders will also be asked for a motor-driven wagon for the same use.

Winnipeg, Man.—Tenders for the construction of 84.72 miles of the aqueduct of the Shoal Lake water project, costing approximately $8,729,000, will be called by the Administration Board of the Greater Winnipeg water district, and they will be opened September 19. The work will be divided into five sections, exclusive of the Indian Bay intake. The aqueduct will extend from the reservoir site beyond Transcona to the Shoal Lake end.

Toronto, Ont.—The controllers last Friday approved of the specifications submitted by Works Commissioner Harris for the Don section of the Bloor street viaduct, and decided to call for tenders immediately. Although the specifications are for steel, the city council has already issued instructions to the Board of Control to call for both steel and concrete, but the contractors tendering in concrete are supplying their own specifications. There are 70 drawings in Mr. Harris' steel specifications.

Renfrew, Ont.—At the regular meeting of the town council on July 1, a by-law was introduced by Councillor Macdonald to establish a fire limit within the town and for regulating the erection of buildings within such limit. It duly received the necessary three readings. A by-law was introduced by Councillor Murphy and passed, providing for taking the votes of the electors on the by-law to install a new electric lighting system. This latter by-law also received its third reading, which is to raise, by way of a loan, the sum of $16,000 to install the proposed new electric lighting system.

Marmora, Ont.—Owing to the frequency of fires, residents realize the necessity of some system of fire protection. Business men and others have been considering the matter for some time, and a proposition is to be submitted to the ratepayers. Last year the fire loss was $35,000, which is a tremendous amount for a town of this size. In most cases these fire losses could have been greatly reduced if there had been a system of fighting the fires. There have also been serious fires this year, the most serious being on May 24, when several thousand dollars' worth of property was consumed.

Regina, Sask.—The Regina city council has adopted the commissioners' report regarding the reduction of the works program for the current year. The total expenditure is reduced from $3,589,518 to $2,237,165. It is not proposed to construct this season the Hamilton street bridge or the new fire hall. Works will be undertaken practically as follows: Extension to power and light distributing system, $380,000; general expenditure on waterworks, $250,500; pavements, approximately $147,000; general hospital, $111,000; sewers, storm and domestic, about $158,000; sewage disposal works and sewer connections, about $72,000; completion of Broad street subway, about $17,000.

Personal

Charles Dow, the general manager of the Mersey Docks and Harbor Board, of Liverpool, Eng., has sailed on the Megantic for the Old Country.

Thomas Long, of Toronto, vice-president of the Collingwood Shipbuilding Co., has been created a Knight of the Order of St. Gregory the Great by the Pope. This is a lay order and the recipients are honored for extreme friendship to the church.

H. K. Clark, who for the past six months has been with the Wilt Twist Drill Co., of Can., Ltd., Walkerville, Ont., having completed his work, in the organization of a sales department, is now with the Agnew Elec. Welder Co., as manager of their Canadian factory at Walkerville.

Lieutenant Owen Lewis, R. N. R., who has been commander of the Royal Mail Steam Packet Chignecto since she has been engaged in the service between Halifax and the West Indies, has been recalled by his company to take command of one of the R. M. S. P. Co.'s trans-Atlantic liners.

Edward W. Cox, director of the Canadian General Electric Co., Ltd., Toronto, died at Folkestone, England, on June 27, following an operation. Mr. Cox was born in Peterborough in 1864 and was principally identified with the Canada Life Assurance Co., succeeding to the presidency after the death of his father, Senator Cox.

E. W. Alderman, an experienced refrigerating engineer, who has been connected with the Vilter Mfg. Co., for a good many years has been appointed manager of the Pittsburgh district, and will have his headquarters at 314 Curry Bldg., Pittsburgh, Pa. He succeeds Mr. H. W. Loecher, who has been transferred and will be located at the main office in Milwaukee.

J. P. Case has been appointed Canadian representative for the Brown Hoisting Machinery Co., succeeding F. A. Peck, who has resigned. Mr. Case has been identified with the Brown Company for many years and is entirely conversant with all Brown hoist products. He will spend all his time in Canada and will be assisted in his work in this territory by Hoyt E. Hayes.

Major R. W. Leonard, owing to the near completion of the Transcontinental Railway and the demands of his private

affairs upon his time, has tendered his resignation as Transcontinental Commissioner, and an Order-in-Council was passed by the cabinet recently accepting it, and leaving the work of the commission to Hon. Frank Cochrane, Minister of Railways. A bill adopted at the recent sessions enables the Minister to exercise the powers, and discharge the duties, of the commission and under his personal supervision the work will be completed.

Tenders

Winnipeg, Man.—Tenders were received by the undersigned up to Monday, July 6 for the erection of a brick and stone school building at Charleswood, Man. E. D. Tuttle, Architect, 709 McArthur Building, Winnipeg.

Medicine Hat, Alta.—Tenders addressed to James L. MacCallum, secretary of the Medicine Hat School Board, and indorsed "Tenders for Heating, Ventilating, Plumbing and Gas Fitting of the Primary School," will be received up to July 13th, 1914.

Winnipeg, Man.—Tenders are being received Tuesday, July 14, 1914, for the supply of Ornamental Lamp and Trolley Poles. Instructions to bidders, specification and form of tender may be obtained at the office of the City Light & Power Department, 54 King street, Winnipeg. M. Peterson, Secretary.

Ottawa, Ont.—Tenders will be received until Tuesday, July 14, 1914, for dredging required at Kincardine, Bruce Mines, Port Hope or Little Detroit, as the case may be. Combined specification and form of tender can be obtained on application to R. C. Desrochers, Secretary, Department of Public Works, Ottawa.

Toronto, Ont.—Tenders will be received for the building of an addition to the Macpherson Avenue hydro sub-station, including excavations, masonry work, brick work, steel work, etc., until Thursday, July 16, 1914. Plans and specifications may be seen and consulted at the Station Construction Office, Duncan Street sub-station.

Toronto, Ont.—Tenders will be received up to Tuesday, August 18th, 1914. For the installation of coal and ash handling apparatus at the main pumping station. Specification and tender form for the foregoing may be obtained upon application at Room 12, Purchasing and Accounting Section of the Department of Works, City Hall.

Grimsby, Ont.—The Queenston and Grimsby Stone Road Committee will receive tenders for the building of a steel bridge with a concrete floor, span about 32 feet, width about 28 feet, over the Forty Mile Creek, in the Village of Grimsby. Plans and specifications may be seen at the office of W. B. Calder, Grimsby. Tenders will be received up to July 11th, 1914.

Edmonton, Alta.—Tenders are now being called by the Edmonton Exhibition Association for several building improvements at the exhibition grounds that will result in a relief to the congestion now experienced in several departments connected with the summer fair. The programme includes an addition to the manufacturers' building, two new cattle barns, one new sheep barn and an up-to-date lavatory.

Prince Rupert, B.C.—Tenders will be recived by E. A. Woods, city clerk, Prince Rupert, up till Monday, July 20, 1914, for the supply of approximately 8,000 linear feet of 6-inch and 2,000 linear feet of 10-inch diameter steel pipe and fittings. Specifications and forms of tender may be obtained at the City Engineer's office, Prince Rupert. W. McGeorge Mason, city engineer.

Ottawa, Ont.—Tenders will be received until Monday, June 27, 1914, for 270,000 lbs. of galvanized iron telegraph wire, deliveredat Montreal, Que.;also 342,000 lbs. of same delivered at Vancouver, B.C. Specification and forms of tender can be obtained on application to the office of the General Superintendent at the Government Telegraph Service of the Department of Public Works, Ottawa, R. C. Desrochers, secretary.

Orillia, Ont.—Tenders will be received by the secretary of the Orillia Water, Light & Power Commission, for the following works, until Monday, July 27, 1914: (A) laying water mains; (B 1) constructing reinforced concrete, coagulating tank and pump house foundation; (B 2) constructing brick pump house; (C 1) furnishing cast iron water pipe and specials; (C 2) furnishing steel water pipe and specials; (D) furnishing gate valves and hydrants; (K) laying of intake pipe in Lake Couchiching. Plans and specifications may be seen at the commission office, Orillia, Ont.

Orillia, Ont.—Tenders will be received by the secretary of the Orillia Water, Light & Power Commission, Orillia, for the following works, until Tuesday, Aug. 4, 1914: (E) Furnishing and erection of motor-driven turbine pumps and equipment; (F) furnishing and erection of "Diesel" oil engine and appurtenances; (G) furnishing and erection of mechanical pressure type filtration plant. Plans and specifications may be seen at the Commission office, Orillia, Ont.

Ottawa, Ont.—Tenders will be received until Monday, July 27, 1914, for 23 knots of single conductor submarine telegraph cable (107 lbs. copper and 150 lbs. guttapercha per knot) with sheathing of 12 No. 8 s.w.g. iron wires, to be delivered at Halifax, N.S., within eight weeks after order if one is given. Also for 14 knots same as above on several reels for distribution to be delivered at Vancouver, B.C., earliest dates of delivery desirable. Specification and forms of tender can be obtained on application to the office of the General Superintendent of the Government Telegraph Service at the Department of Public Works, Ottawa, R. C. Desrochers, Secretary.

Shoal Lake, Man.—Tenders, addressed to the undersigned, will be received up till Thursday, 16th July, 1914, for the following contracts: 1. Furnishing and installing generator, exciter and switchboard; 2. Furnishing transformers and meters; 3. Construction of brick power house building. Plans and specifications may be seen at the offices of the Consulting Engineers at Winnipeg and Calgary, and at the town hall, Shoal Lake. A deposit of $25 will be required on Contract No. 3, which will be returned to bona fide tenderers on return of the papers. F. Dobbs, secretary-treasurer, Shoal Lake, Man. The John Galt Engineering Co., consulting engingeers.

Trade Gossip

Mussens, Ltd., Montreal, have received an order for a "Ruston-Proctor" steam road roller to cost $4,000.

The New York Continental Jewel Co., New York, will install a mechanical filtration plant at Laval des Rapides, Que.

Ottawa, Ont.—A special meeting of the shareholders of the Lake Erie & Northern Railway Co. has been called for August 4 in Montreal to consider the advisability of leasing the line to the Canadian Pacific Railway. It is proposed to cancel a mortgage securing $500,000 of second mortgage bonds and to provide a new mortgage to secure a new issue.

The Dominion Government have placed orders for supplies for the Departmental Dredging Branch during the fiscal year 1914-15 as follows: for Prince Edward Island—chain, W. H. Thorne & Co., St. John, N.B.; hose, Geo. T. Polly, St. John, N.B., and the General Supply Co., of Canada, Ottawa; oils and greases, the British American Oil Co., Ltd., Montreal; paint, paint oils, etc., R .C. Jamieson & Co., Montreal; Manila rope, Consumers' Cordage Co., Montreal; wire rope, Poole & Thompson, Montague, P.E.I.; steam pipe, valves and fit-

tings, the Canadian Fairbanks-Morse Co., St. John, N.B. The supplies were ordered for Ontario and Quebec as follows: chain, Lewis Brothers, Ltd, Montreal; hose, the Canadian Fire Hose Co., Montreal, and the Builders' Supply Co., Ottawa; oils and greases, W. F. Kelly Oil Co., Kingston; paint, paint oils, etc., the Ottawa Paint Works, Ottawa; Manila rope, Consumers' Cordage Co., Montreal; wire rope, Drummond, McCall & Co., Montreal; steam pipe, valves and fittings, Empire Mfg. Co., London, and Samuel Fisher, Registered, Montreal. For Nova Scotia and New Brunswick, orders were given thus: chain, Norman S. Sancton, St. John; hose, Estey & Co., St. John; oils and greases, the British American Oil Co., Montreal; paint, paint oils, etc., R. C. Jamieson & Co., Montreal; Manila rope, Consumers' Cordage Co., Montreal; wire rope, the General Supply Co., of Canada, Ottawa; steam pipe, valves and fittings, the Canadian Fairbanks-Morse, Ltd., Montreal.

Contracts Awarded

Welland, Ont.—The Standard Crushed Stone Co., have been awarded a contract for making 34 miles of good roads at $4,850 per mile.

Westmount, Que.—The council has awarded a contract to Eugene Phillips & Co., Montreal, for the supplies of wire cable amounting to $17,707.

Fort William, Ont.—A contract has been awarded the Varlow Foundries, Ltd., for the heating plant for a new school building. The contract price was $9,700.

Port Burwell, Ont.—The contract has been awarded by the Dominion Government to the C. S. Boone Dredging & Construction Co., of Toronto, for dredging this port.

Montreal, Que.—Contracts have been awarded by the Protestant School Commissioners for heating and ventilation of the new Rosemount school to A. Bethune, at a cost of $25,800; and for electric wiring, to Collyer & Brock, at a cost of $3,555.

New Toronto, Ont.—Contracts for the biggest part of the work in connection with the water works have been fixed by the council. Out of six tenders for the supply of water mains, hydrants and valves, the Canadian Allis-Chalmers, Ltd., of Toronto, was successful, their figure being $11,841.

Winnipeg, Man.—The following contracts have been awarded by the Board of Control for the installation of induction regulators: The Canadian General Electric Co., for two 3-phase regulators at $4,625; The Canadian Westinghouse Co., for 2 single-phase regulators at $2,071. Engineer, J. G. Glassco.

New Toronto, Ont.—The offer of the Cargo Bridge & Iron Co., Bridgeburg, Ont., to supply a 75,000-gallon steel tank with tower for $4,450 was accepted, being the lowest of four tenders. There were three offers for an 18-inch steel intake pipe and that of the Thor Ironworks Co., Toronto, at $2.25 per foot was accepted.

London, Ont.—The London and Port Stanley Railway Commission has awarded contracts as follows: Angle bars and tie plates, Algoma Steel Corporation; spikes, J. J. Gartshore Co., Toronto; track bolts, Steel Company of Canada; guard rails and switch stands, Canadian Ramapo Iron Works; and concrete pipe, Canadian Concrete Products Co., London.

Kelowna, B.C.—Contracts for the new equipment for the power house as follows: 322-h.p. engine, to The Goldie & McCulloch, Galt, at a cost of $3,810; condenser and 400 h.p. heater, to the same company, at $626 and $527 respectively; generator and exciter, 150 k.w., Canadian General Electric Co., at $2,333; switchboard panel, the Canadian Westinghouse Co., at $400.

Ottawa, Ont.—The Government has awarded contracts for the substructures of a number of new bridges it is proposed to build along the Intercolonial Railway. The successful tenderers are as follows:—W. M. Leacy, Prescott, Ont. —Kamouraska Bridge, $2.938; St. Jean Port Joli Bridge, $4,326; crossing over N. T. R., $9,548; Black River Bridge, $4.424. R. S. and J. H. Henderson, North Bay, Ont.—River Bras St. Nicholas, $24,252, and River Du Sud Bridge, $37,903. W. R. Fawcett, Temperance Vale, N.B.—Kouchibouguacis River, $7,-182; Barnaby River, second crossing bridge, $2,425; bridge half mile west Sayabec, $2,773; Black River Bridge, $1,699, and French River Bridge, $6,448. R. B. Stewart, Derby Junction, N.B.— Barnaby River, third crossing bridge, $11 288. McDonald and McIntosh, Antigonish, N.S.—Barney's River, east crossing bridge, $2,397, and Barney's River, west crossing bridge, $2,959.

Building Notes

Medicine Hat.—It is proposed to build a technical school here, to cost $300,000.

Saskatoon, Sask.—MacDonald's Consolidated, of Winnipeg, will build a warehouse here.

Ottawa, Ont. — J. A. Langelier has purchased a site for $28,000, and will probably build a warehouse.

Galt, Ont.—The site is being cleared and erection of the new Armory to cost $75,000 will soon be commenced.

Cochrane, Ont.—A new public school will be built here at a cost of $30,000. Architects, Angus & Angus, North Bay.

Brantford, Ont. — The Brantford Realty Co., will erect a factory to cost $28,000. Architects Barber & Tilley, Brantford.

Toronto, Ont.—The Crofton Storage Battery Co., will build a brick warehouse at 423 Queen street west, to cost $20,000.

Toronto, Ont.—J. A. Thatcher has obtained a permit to erect a 6-storey brick warehouse at No. 9 Laplante avenue, to cost $30,000.

Calgary, Alta.—The Calgary Oil & Stock Exchange will erect a new exchange building at a cost of $75,000. Mr. Jause, of Janse Bros., contractors, is the president.

Toronto, Ont—Frankel Bros. have obtained a permit covering a five-storey warehouse on George street, near Duchess. The building will be five storeys in height exclusive of basement. The estimated cost is $62,000.

Penticton, B.C.—James J. Warren, president of the Kettle Valley Railway, has submitted a proposition to build a warehouse for the Fruit Union for certain considerations. The cost is not to be more than $25,000.

Winnipeg, Man—The Farmers' Supply Co., Ltd., will build a large warehouse here at an estimated cost of $45,-000. The building will have four stories and basement with provision made for adding additional stories when necessary.

Toronto, Ont.—Building permits were issued last Friday by the City Architect's Department for two new temporary incinerators, which will cost all told $26,000. Both structures will be of steel, the one at Eastern avenue and the Don Esplanade costing $9,000, while the other at Strachan avenue is to cost $17,000.

Toronto, Ont.—All the plans and specifications for the new Registry Office to be constructed over the whole block lying between Albert, Louisa, Elizabeth and Chestnut streets have now been received and bulk tenders will be called immediately for the work. It has been decided to construct the foundations of sufficient strength to permit the addition of a third story in the future. The building will practically be one huge fireproof vault.

Wood-Working

Elmira, Ont.—The Elmira Furniture Co. are building an addition to their factory.

Brockville, Ont.—The Briggs Planing Mill Co. mill was recently destroyed by fire at a loss of $18,000.

Aylmer, Que.—T. Ritchie & Co., have started work on the rebuilding of their saw mill. Electrical equipment and woodworking machinery will be required.

Brockville, Ont.—Fire recently destroyed the planing mill of the James Smart Mfg. Co., Ltd. The damage is estimated at $20,000, partly covered by insurance.

Cobalt, Ont.—The Fairview Mfg. Co.'s sash and door factory at 2058 Sixth avenue west, was totally destroyed by fire on June 22. The total loss is estimated at $23,000. The factory and contents were insured for $13,000.

Peterborough, Ont.—Fire broke out at the McDonald Estate Lumber Co. plant last Wednesday totally destroying the shingle mill and entailing a loss of about $3,500 to buildings and machinery which is partially covered by insurance.

Railways—Bridges

Ottawa, Ont.—The Morrisburg and Ottawa Electric Railway Co. will extend the line from Ottawa to Chesterville. L. Von Lydow, engineer.

Toronto, Ont.—The Toronto and York Radial Co., will rebuild the car barn on the lake shore road. The building will be a frame structure with galvanized iron, and will cost $4,000.

Brantford, Ont.—The contract for the bridge across the Grand River in connection with carrying the Lake Erie Railway line from this city to Port Dover, has been let.

Victoria, B.C.—The Johnson street bridge will cost about $700,000. That figure includes the land damages. Of the total the city will contribute about $400,000, and the by-law will be introduced at a city council meeting shortly.

Montreal, Que.—It is announced that the Canadian Northern Railway has decided to erect a temporary station fronting on Lagauchetiere street, that they would begin work almost at once and that the cost would be in the neighborhood of a quarter of a million dollars.

Vancouver, B.C.—Track-laying will be resumed on the Canadian Northern Pacific Railway from Kamloops to a point twenty-eight miles west where the right-of-way crosses the Thompson River, in the course of a few days, according to an announcement made recently by officials of the railway's engineering department. Steel has been on the ground for some time and the balance of the material and equipment necessary for laying this stretch of track is now on the way to Kamloops and immediately upon its arrival work will be started. The rails will be held up at the Thompson River until a bridge has been completed across, then another section of the road will probably be built and the uncompleted portion of the work between Cisco and Kamloops somewhat diminished. The steel for the bridge across the Thompson has already been frabricated and as soon as the rails reach the river, work will be commenced and rushed ahead on the erection of this structure.

New Haven Mellen.—W. S. Mellen, former president of the New Haven and allied railroads, has told the story of the manipulation of the stocks of the roads with an amazing cynicism and indifference—or rather with a sense of biting humor, coupled with an owl-like gravity in the box, absolutely unparalleled under the circumstances. He has shown how completely he was under the thumb of the late Pierpont Morgan, who made him president of several roads by telephone; who manipulated the stocks and controlled the whole situation as powerfully and relentlessly as the Czar of Russia. Stocks were exalted and depressed, peddled around, and sold at last by the pound weight, as Mr. Mellen said, with a whimsical humor. The imperturability of the latter; his inconsciousness of anything unusual as far as his relations with Morgan and the roads are concerned; his astounding frankness, coupled with his ability and mordant humor, conspire to form a picture unique in the outstanding feature that mark it.

New Incorporations

The National Tube Co., Ltd., has been granted a license to carry on business in Ontario. Attorney, Harry Rooke, of Toronto.

The American La France Fire Engine Co., of Canada, Ltd., has been incorporated with $50,000 capital. The head office is in Toronto.

The Detroit Sulphite Pulp & Paper Co., have been granted a license to carry on business in the Province of Ontario. Attorney, Robert Bartlet, of Windsor, Ont.

The Northern Trap Rock Co., has been incorporated at Toronto with a capital of $1,000,000 to quarry stone at Toronto. Incorporators: H. A. Hall, J. J. Flint, and W. B. Henderson, of Toronto, Ont.

The Excelsior Electric Mfg. Co., Ltd, has been incorporated at Toronto, with a capital of $40,000, to deal in electric motors at Toronto. Incorporators: L. T. Rutledge, N. H. Manning, and W. E. Carman, of Toronto.

Gardner & Gaskill, Ltd, has been incorporated at Quebec with a capital of $40,000 to carry on business as contractors at Montreal. Incorporators: G. P. Soady, H. E. S. Adams, and C. M. Cotton, all of Montreal.

The Hall Engineering Works, Ltd, has been incorporated at Ottawa, with a capital of $200,000, to carry on business as engineers at Montreal. Incorporators: T. Hall, F. H. Fox, and R. B. Proctor, all of Montreal, Que.

The Galt Wire & Ornamental Iron Co., Ltd., has been incorporated at Toronto, with a capital of $40,000, to manufacture iron goods at Galt. Incorporators: J. Spalding, of Hamilton, R. J. Spalding, and A. E. Moore, of Galt.

The Hedley Shaw Milling Co., has been incorporated at Toronto, with a capital of $1,000,000 to carry on the business of grain millers at Toronto, Ont. Incorporators: W. D. Toye, A. E. Moysey, and A. Mullin of Toronto.

The Chaleurs Bay Pulp & Paper Co. has been incorporated at Ottawa with a capital of $100,000 to manufacture pulp and paper at Sherbrooke. Incorporators: H. R. Fraser, F. S. Rugg, and H. M. Terrill, all of Sherbrooke, Que.

The Niagara Falls Pickles, Ltd., has been incorporated at Toronto with a capital of $40,000, to manufacture pickles at Niagara Falls, Ont. Incorporators: H. F. Naisbett, J. Forde and T. E. Nicholls, of Niagara Falls, Ont.

The Independent Silk Co. has been incorporated at Ottawa, with a capital of $100,000 to manufacture silk goods at Montreal. Incorporators: T. E. Herlihy, J. J. O'Grady, of Westmount, Que., and A. F. Dillon, of Montreal, Que.

The Canadian David E. Kennedy, Ltd. has been incorporated at Ottawa with a capital of $10,000 to carry on business as contractors at Montreal. Incorporators: F. H. Markey, W. W. Skinner, and W. G. Pugsley, all of Montreal, Que.

The J. H. Hamilton Shoe Co., has been incorporated at Ottawa with a capital of $100,000 to carry on the business of boot and shoe manufacturers at Sherbrooke, Que. Incorporators: J. H. Hamilton, of Levis, J. A. LaRue, and E. Trudel, of Montreal, Que.

Scientific Management Results in Automobile Factory *

By G. D. Babcock **

The principle discussed in the entire paper is that of a task and the accomplishment toward the task in magnitude and rate; being the foundation for the belief that any plan of effort which focuses toward a desired result will cause an accomplishment more perfect than before, and the rapidity of this accomplishment will be measured greatly by the intensity of the plan which directs to the focus.

A DESIRABLE attainment and one which influenced us to direct our attention to the Taylor principle of scientific management was the elimination of the peak load of employment of workmen. The tendency in automobile production has been to follow very closely a schedule established by public sentiment and seasonable demand, with the result that labor to produce was drawn from a normal market, and usually about the time that the market had again filled was thrown back on it.

Community Relation to Industries.

If a community could so select its industries that the average peaks of laborers employed in all of the individual industries gave a uniform load of all labor in the community, it would be well worth the time of the civic organizations to try to secure such industries for their community as would tend to level this peak load. Of course, if individual industries could level their particular load this would automatically care for itself, and although this can be approached in a very marked way, it cannot be as perfect as in the case where industries have been selected by a community for this particular quality.

Some causes of peak load in the employment of workmen beside that of management are uncertainty of demand for product, seasonal demand for product, small capital invested in the business, strong competition with small margin of profit, any of which can be materially improved by plans founded upon analytical study and constructive action.

Our experience has been that, through applied scientific management, efficiencies have been created, sales have been enhanced, due to better deliveries, and lower price and greater confidence of the purchaser have come about by the uniform standard of the quality of the product. This has been further affected by good service, better temper of the sales organization due to promise of delivery being kept, a better impression among those who have come in contact with our works or with the workmen, through seeing the more orderly condition of our plant, and the better feeling of the workmen themselves as reflected in their expressions.

It is no reflection on a management to secure the advice of specialists in methods of operation. Not a day goes by but representative specialists of machine tool manufacturers advise us that we are in the dark ages of shop practice; and this practice perhaps rests upon their product of but a year ago. Structural and tool steel specialists are sure that if we change from their material which we are now using to others of particular chemical analysis our results will be greatly enhanced. We know that it is wise to listen to their advice. The viewpoint is, however, quite different. In the one case we seek for advice that we wish to buy. In the other, the specialist has something which he wishes to sell. They are both good, and have their place in our industrial development.

The writer was in a responsible position with this company some years before this practical task plan of work was started, and the deductions are from data which was compiled by him over the periods mentioned. There is no attempt to suggest how others may do, and no offer of panacea for poor management. I am trying to relate an experience of the application of a much considered and discussed form of management as translated by one manager for his particular business.

Stores Department Overhauled.

The first application of the work was on our stores requisitioning, purchasing, receiving and issuing. Up to this time we had had a relatively inaccurate annual stores inventory. Although we inspected incoming materials, and that very rigorously, the inspection was not performed before their receipt into store. Invoices were passed on receipt; and having no particular pressure on it, inspection consumed a great amount of time and caused delay in moving out of stores. This plan was changed, and inspection of raw materials was made before the purchase order was credited with the receipt of the goods. At first this was a difficult task, since the passing of invoices was delayed, but at the present time it demands little of our attention to maintain it permanently in a first-class working form.

Due to the fact that the plan of progress was rather arbitrary and different individuals worked according to their own best translation of what should be done, the burden at times on the inspectors and receiving clerks was tremendous. Express and freight shipments ran high at times and caused a serious amount of overtime work with its incident confusion and inaccuracy. The control plan, which will be described later, has practically eliminated this difficulty, and the flow of materials now in stores is very smooth and uniform.

The receiving clerk had no knowledge of what to expect in any given package, but would try to record what he found. The assumption was that he would be more accurate and would not be liable to assume, but this theory has been completely exploded by our more recent experiences. He is now supplied with a copy of the purchase order placed with the vendor, and thus knows exactly what to expect from the vendor. When the count is made for the passing of the invoices of small materials, like forgings, castings, etc., that can be bagged, they are counted out not by tens or some even number, but in the size of the outgoing lot.

They are then bagged in these lot sizes, wire is wrapped around the bag and through the cloth, and a lead freight-car seal locks it. A tag with proper data is attached, and the material is sent to the bin location as marked on the stores receiving clerk's copy of the purchase order. This bin location is carried by the stock tag when closed (and we have a stock bin tag for each lot of material) to the store's balance sheet. When a requisition is written by the balance clerk, he adds old location, which is the usual assigned location. This has eliminated much confusion due to moving materials on receipt of new lots to new places in the stockroom. The possibility of bagging this material in standard lot sizes is due to the control plan mentioned.

Purchasing Department Experience.

The purchasing department was forever rushing or holding up orders, and, of course, the parties from whom we purchased had the same experience. In the recent year or so our orders have been placed with such regularity that within a few days that they should receive an order, some of our vendors call and ask if they shall make preparations for an order which is due.

The purchasing department has materially reduced its cost, and seems to

*Part I. of a paper presented at the National Metal Trades Association convention, held on April 22, at Worcester, Mass.

**Production manager, the H. H. Franklin Co., Syracuse, N.Y.

be exceptionally happy under the new order of things. Perishable goods have been put under a double bin system, and others will be as fast as we can physically arrange for it. In this double bin system the receipt of material is not confused with outgoing, or on hand. Issues bring the bin stock tag to a flat zero, as one-half of the bin is emptied. It allows extraordinary check of materials on hand, and it takes the stock man in as a factor in accurate record.

Rejected materials are handled with dispatch. Surplus has been very materially decreased and the equivalent store's investment reduced. The quick handling of the stock in the room, on account of all lot sizes being maintained standard, and the delivery to the shops and through the shops has furnished a considerable amount of our savings.

To sum up the stores situation, the peak has been practically swept off and the employees feel but a uniform burden of effort. We have practically no experience of the "Unexpected Happening." The same features that affected the stores department marked the experience of the purchasing department.

Classification of Stores.

Coincident with the initial planning for the handling of stores, we began the classification of stores and the reconstruction of the clerical methods of handling the accounts so that they would be of prime use to the works as well as to the accounting department.

The accuracy of our stores inventory has increased each year due to this careful work and the particular method employed of checking, until now with a considerably less number of clerks we have a very much greater amount of information. This information is accurate. As evidence of the latter the auditors of our stock company gave us a clearance for the last year of 0.3 per cent. error of stock on hand, and approximately 0.03 per cent. error on the transactions in and out of stores for the year. This clearance was determined by a detailed check of our ledgers and material on hand and of the accounting department records.

Old Order of Things.

The classifying of product, another movement started at the outset, had a marked effect upon our works' effort. Previously our manufacturing orders called for miscellaneous parts or assemblies, and the assembly order contained a specification of the parts which were to be used in that assembly. Parts orders were written independently of the requisition for material. No date was specified for the part to be due in finished stores. The orders were written in quantities of 25, 50, 75 and 100, and in general it did not matter whether the part was small or large, except in the case of automatic and screw machine work or punch-press work, when an order for the full quantity for the season was usually written.

These orders were not apportioned to the material ledgers, and therefore it was a case of the most persuasive foreman getting from stores the material for his parts. He could draw from stores on requisition at any time that he could find some material, and unless he had a shortage could finish his order at any time he saw fit. He had a schedule for parts to guide him. This consisted merely of a schedule of the month's production for the different types of cars, but set back as many months as our progress clerk assumed the works would need and still deliver them safely into the finished stores room in time for the issue to assemble. We had but few small subassemblies. The single group issues for one of our large assemblies might require as high as a quarter of the variety of parts in the finished stores.

After the assembly order was issued it was given to the finished stores keeper, who was supposed to deliver the materials to assembly against that order as rapidly as possible. When first parts of a lot were delivered to the assembly floor the assemblers started to put them together, and from that time on chasers tried to force the parts which were lacking through the shops on the remaining operations, and in and out of the finished stores room to the assembly floor. It was a merry chase.

One result of this was that operation set-ups veried from 1 to 100 pieces, and on the same part might vary in this complete scale. With an average of ten operations on different drawing numbers or parts to each machine, and with the preparation time of the machines uncertain, confusion resulted by interference of orders from the different shortage chasers. Very high costs were thus created. We produced cars, however, for a great many years under these conditions, and still believe that we represented a relatively high order of working efficiency in the automobile industry of the time. Engineering changes were frequent, the demands of the buying public were uncertain, and then it seemed to us to be the only way of solving the problem.

Now we can see how it could have been solved in a very much better way even with the full complication of a variety of models and many changes. When we began the classification of our products the elimination of this confusion and trouble also began. Through the findings by the classification of this product, our whole scheme of control of work has come about. The scheme of classification is briefly this:—

Classification of Products.

The first two parts made which can be fastened together as a part of the finished structure are fastened together and turned into finished stores. This unit and other parts and fastenings are issued from stores, are essembled into a larger group and then turned back into stores. This continues throughout.

In this classification we discover that in the new car, where our lot sizes have been adopted to the standard as used at present, we must make the requisition of our first piece 200 working days ahead of the time that the car can be finished. It is important, therefore, that we not only check by assembling the condition of our product, but that the lot sizes of assemblies be proportioned economically as well as lot sizes of parts. The flow of the different parts into the sub-sections, into sections, divisions, groups, and finished product, are charted, and with detail parts entered with symbols constitute the parts analysis of our product.

On each part we determine the mechanical operations through which it must go. This is also true of the assembles. We study the size and form of the materials to use, also whether patterns, dies or tools must be prepared, and, in fact, all that we can of the product in its last detail from the standpoint of the factory effort upon it. The time element is a very important factor in this analysis, both on account of certainty of delivery and of valuation of material and labor investment. The analysis of the product furnishes the groundwork on which our control rests.

Analysis of Product Discovery.

Upon the first analysis of our product we found the cause of one of the greatest troubles that we had experienced; i.e., our inability to attain a schedule that seemed perfectly possible. Thirty-nine parts in our whole car were the cause of this, and the two longest time parts in this list were two of the cheapest things put into our car. the cylinder flange and the exhaust valve. All of our effort on product analysis alone was well repaid by this one discovery. Standards were made for these parts and the time between the first effort on the first part and the finish of the completed car was greatly reduced. Later discussion of the uniform schedule will show another very important result attained after this study that has to do with the investment of capital.

Moving Materials.

With regard to the method of moving materials on ground floors, concrete pits are sunk in the floors and properly guarded. An electric transportation truck runs into the pit to bring its

platform level with the floor. The truckman lifts the material from the shop floor with a power hand-truck and runs the load upon the electric truck; he then withdraws the hand-truck, runs the electric out of the pit to the new destination, where it either goes into another pit on the ground floor or to an elevator, if for the upper floors.

The load is handled from the elevator much as if the elevator were a pit. The electric truck runs in with its side to the sill. The elevator is operated to raise the truck to the particular floor level on which the load is to be delivered. The load is then removed to the floor with a power hand truck, and the elevator lowers the electric truck to the ground floor and releases it. The elevator man returns at his first opportunity and delivers the load to its proper place.

In connection with the bagged materials spoken of and the adoption of a universal size of a particular part lot, economical results of handling materials, as mentioned previously, were obtained. In addition to this, the labor of the movemen has been very much lightened, and one man can deliver a thousand pounds from stores to any place in the works with greater rapidity and ease than he could carry a pail of water over the same path. The lack of fatigue of the moveman allows a high rate of travel throughout the day. Where, before, movemen would ignore a pile of heavy material until they were forced to carry it, now they take whatever comes as it comes.

NEW REAGENT FOR ETCHING STEEL.

A new reagent for etching mild steel for purposes of microscopic examination was offered by Walter Rosenhain and J. L. Haughton in a paper before the London meeting of the Iron and Steel Institute, May 7 and 8. In attempting to etch a copper alloy which was attached to a plate of mild steel, the authors employed the ferric chloride reagent ordinarily used for etching brass or bronze. They noticed that while the steel was exposed to the reagent the copper alloy was not acted upon, as was natural, but that the reagent exerted a distinct etching action on a portion of the attached steel which had been polished. The appearance of this was so interesting that they decided to investigate further. So far as their results have gone, the authors have found that in order to secure satisfactory and uniform action it is necessary that the composition of the new reagent should conform to the following formula:

Ferric chloride (Fe_2Cl_6), 30 grams.

Hydrochloric acid (conc.), 100 cubic centimeters.

Cupric chloride ($CuCl_2$), 1.0 gram.

Stannic chloride ($SnCl_2$), 0.5 gram.

Water, 1 liter.

These proportions have been arrived at after a considerable number of trials in which the composition was rather widely varied. Its use requires considerable care. Thus far the authors have found that in practically pure carbon steels the new reagent yields a pattern which is the reverse of that obtained with the ordinary etching reagents such as picric acid. On hardened steels, especially those of low and moderate carbon contents, the reagent yields very clear results, particularly in the etching of martensite, although in this case the patterns are not reversed as compared with those obtained with picric acid, sulphur dioxode. etc.

The principal interest and importance of the new reagent, however, lies in the fact that it reveals in a clear and striking manner the distribution of phosphorus, particularly in mild steels, yielding results which compare favorably with those hitherto obtainable by the heat-tinting method devised by Stead. It may be stated at once that the action of the new reagent consists in the deposition on the surface of the steel of thin films of metallic copper.

In a mild steel exhibiting the usual pearlite-ferrite structure it is found that whereas the ordinary etching reagents, such as nitric acid, picric acid, etc., rapidly darken the pearlite by attacking and roughening it, leaving the ferrite practically unaltered, the new reagent reverses this procedure. The pearlite is left untouched, appearing white and bright under normal light, while the ferrite is covered with a film of copper having a slightly rough surface texture, and therefore appearing black under normal light, particularly if the period of etching has been somewhat long.

The resulting effect is, however, striking. When applied to quenched steel, the new reagent yields patterns which are of the same kind as those produced by other means, that is, there is no reversal in this case. It, however, develops the structure of martensite, particularly in low carbon steels quenched from a high temperature, in a remarkably clear manner.

HIGH-SPEED STEEL.

By William Abbott.

For a number of years, attempts had been made to improve upon the self-hardening steel first manufactured by the Mushet Co. and afterwards by most of the principal makers in United States and Europe, with more or less success for some years before the discovery of high speed steel in 1898.

Self hardening steel is a high manganese steel with a percentage of chrome, and is high in carbon. Experiments were made by Taylor and White at the South Bethlehem crucible plant of the Bethlehem Steel Co. They began first by adding ferro-tungston, but with no great success, and it was only by an accident that the proper method of heating tools was obtained. It occurred in this way, and what follows is described by one of those engaged in the work. A test piece was made under the following formula;—

Carbon	.50
Molybdenum	10.00
Chrome	4.50
Manganese	.15
Silican	.20

Tools were shaped and given the blacksmith to heat. He by mischance left them too long in the fire, as he thought, as they were apparently overheated, being burnt at the ends, and only fit for scrap; where they were thrown. They were afterwards picked up by a machinist who wanted a lathe tool, and he ground one for his work. This gave such surprising results that inquiry was made and the secret discovered, proving thereby that the high heat given accidently was exactly what the steel required. After this, the evolution from the old self-hardening to high-heating high speed steel was easy and rapid, and after perfecting their discovery, the Taylor-White Co. took out a U. S. patent for the steel process, and then sold it to the Bethlehem Steel Co., who carried it to the Paris Exposition of that year, where it created quite a sensation. They later sold a number of rights to manufacture. In those early days, it was thought that if the steel were made over .40 in carbon and low in maganese it would be a mistake, but such was not the case,

Since then all the principal steel plants in Europe and United States have taken up the manufacture of this high grade steel, under various designations although all using practically the following same analysis;—

Carbon	.70 to .75
Tungsten	18.00 to 18.50
Chrome	4.50 to 5.50
Manganese	.20 to .24
Silicon	.15 to .20

The sulphur and phosphorous contents are kept very low. Some makers now add about .25 to .50 vanadium while others again put in about 4 per cent of cobalt with good results.

It is not for the writer to make comparisons or show any preference, but during his long experience as a representative of high speed steel, having introduced the first of the new steel into Canada, he is of the opinion that those steels are the best which have as a base, Swedish or Norway iron, other additions being equal.

PRODUCTION METHODS AND DEVICES

A Department for the Interchange and Distribution of Shop and Office Data and Ideas Evolved from Actual Practical Application and Experience

SCREWING AND TAPPING FIXTURE.

By W. G.

THE drawings herewith illustrate an improved screwing or tapping fixture for threading small accurate repetition work. It is of simple construction, most of the machinery being plain turning. A glance at the accompanying drawings will no doubt give a clear idea of its general features.

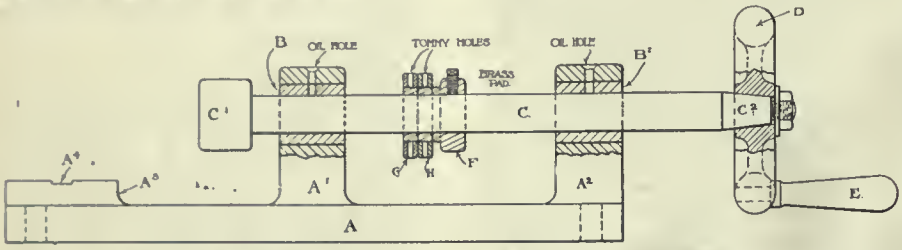

FIG. 1. LONGITUDINAL PART SECTIONAL ARRANGEMENT.

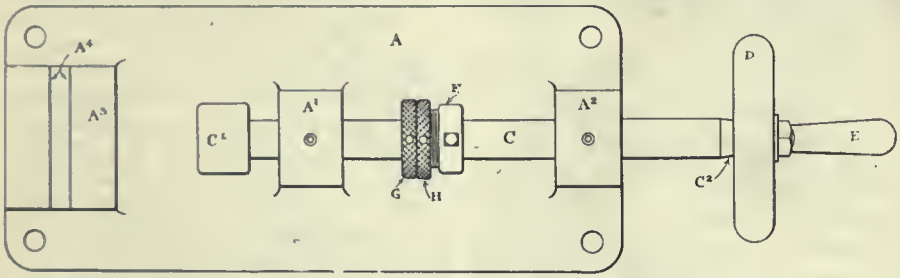

FIG. 2. GENERAL ARRANGEMENT PLAN.

Fig. 1 is a longitudinal part sectional view showing general arrangement of fixture. Fig. 2 is the plan of same, while Figs. 3 and 4 are detail views of the screwing and tapping spindle ends respectively. The fixture body A consists of a rectangular cast iron plate, having formed at one end a pair of uprights or journals A^1 and A^2. It is further provided at its opposite end with a flat projection or facing A^3, through the center of which is formed a tongue groove A^4, this being for the purpose of receiving a corresponding tongue formed on the underside of the tapping or screwing holder, thereby providing means for keeping the said holder quite square with the spindle. It is finally secured to the facing by screws.

The bearing bushes B and B^1 are made from best phosphor bronze, and should be made a good smooth finish in the bore, the outside being a tight fit to the holes in the uprights A^1 and A^2. The spindle C consists of a circular mild steel bar, provided at its extreme end with an enlarged collar or shoulder C^1 for the purpose of receiving the tapping chuck or screwing die, whichever the case may be. The opposite end C^2 is screwed and tapered as shown, for accommodating the handwheel D; this being secured finally to the spindle by means of the nut and washer as shown. Part E is the handle, which is made from mild steel, and should be a tight fit to the hole in the handwheel rim. The adjustable stop consists of a screwed mild steel sleeve F, secured to the spindle C by the set screw as shown. It is further provided with two knurled nuts G and H; these being for the purpose of fine adjustment.

Figs. 3 and 4 are detail views of the screwing and tapping spindle ends respectively. In the former, the recess I is bored out to receive a circular screwing die (flat type), and in the latter the hole J is bored out and screwed to receive an ordinary spring chuck. In each case, however, it is very essential that the holes should be bored out quite true with the periphery of the spindle, thus preventing the possibility of "binding" when screwing or tapping.

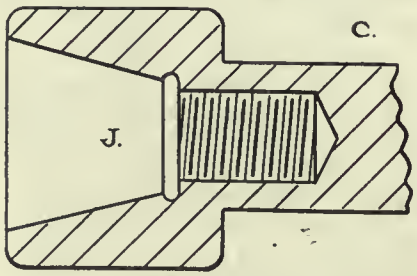

FIG. 4. DETAIL VIEW OF TAPPING SPINDLE ENDS.

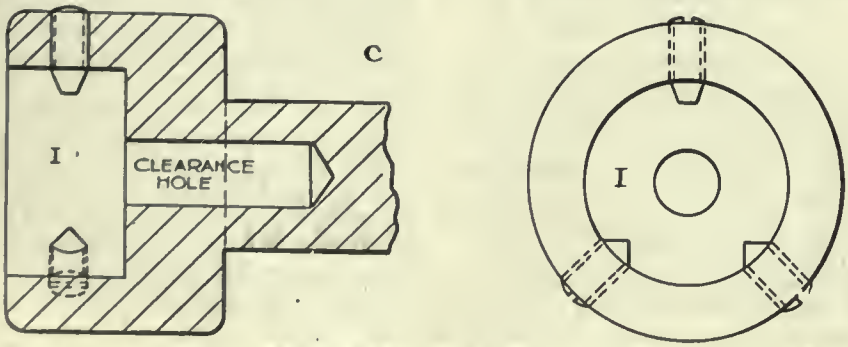

FIG. 3. DETAIL VIEW OF SCREWING ENDS.

ATTRACTIVENESS OF BALL BEARINGS.

By N. G. Near.

ONCE in a while we run across men who proudly point to bearings of their own design that are made to run without oil. Oil is not wanted on the bearings, because it might fly off and ruin the product of manufacture. In most cases, however, that have come under my observation, such bearings are not exactly satisfactory. They heat and squeak.

Ball bearings would certainly do the same work and do it much better. They require a little oil, true enough, but just enough to keep the balls and races from rusting, and are now made so rugged as to be almost as durable, and in many cases more durable, than plain bearings, as Thomas' recent tests, presented before the American Society of Mechani-

cal Engineers, plainly indicate. In textile mills, where cleanliness is a decided necessity in order that the product of manufacture will be perfectly free from dirt and grease, ball bearings are being much used.

Ball bearings are quiet, they do not heat, they are consumers of but little space, and they are the closest approach to frictionlessness that we know of.

BORING MILL PRACTICE.—II.

By Albert A. Dowd.

Figure 4 shows the second setting of the blank A which we have partially machined on the periphery in the first setting. The hard jaws shown in Figure 3 are now removed and the soft jaws U substituted for them. Tools K and M in the main head turret are used to bore these jaws to the size of the finished portion of the blank, and it will be noted that tools are the same as those used in the previous setting. The shoulder V in the jaw is made rather shallow so that a part of the surface previously finished will appear above the top of the jaw. It will be seen that no changes in the set-up of either the main or side heads is necessary for this setting as same tools are used in each instance.

Tool K in the main head is started from the center feeding outward while

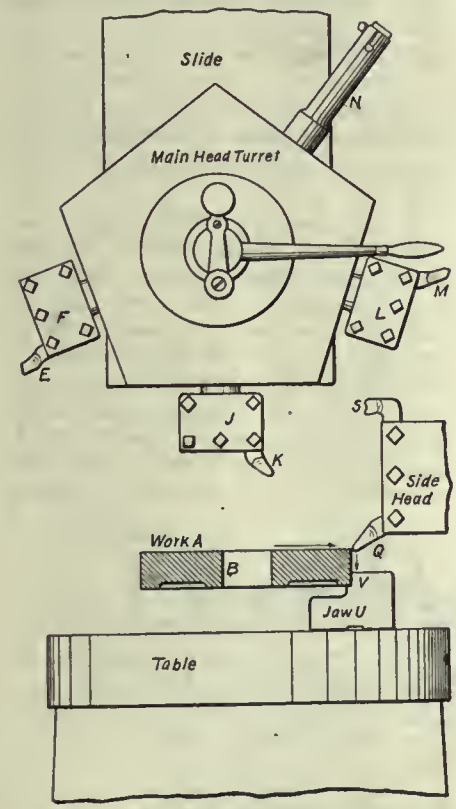

FIG. 4. SECOND SETTING FOR GEAR BLANK.

the side head tool Q feeds inward a short distance on the same surface. The side head is then withdrawn and rough turning is accomplished while the main head tool completes the rough facing. The relieved portion is machined by the

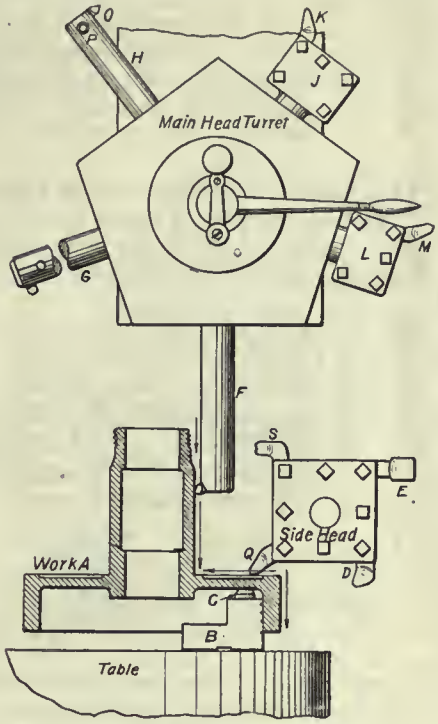

FIG. 5. SET-UP FOR MACHINING FLY-WHEEL PULLEY.

tool S in the side head as in the first setting, while the finish facing is done by the tool M. In completing the outside turning of the blank, considerable care is taken in the first setting. If attention has been paid to the reading of the micrometer dials during the first setting, the same reading will be found of assistance during this operation and less difficulty will be experienced in obtaining the correct diameter. Neither the boring bar N nor the tool E are used in this setting.

Handling a Fly Wheel Pulley With Simple Tooling.

In the machining of the flywheel pulley shown at A in Figure 5, the first step is the reversal of the jaws B and the insertion of raising buttons C so that the work may be gripped from the inside of the rim and supported on the buttons in order to obviate any trouble which might be caused by the fillets in the casting. There are some changes in the tooling also in this setting but five minutes or so is ample time in which to make them. The two holders and tools M and K remain as they were in the main head turret and the two tools Q and S in the side head also remain there. Other stations are occupied by the tools shown.

The first operation consists of rough turning the thread diameter on the upper portion of the hub with the turning bar F, and afterward rough turning the main portion of the hub itself with the same tool. As soon as the roughing diameter of the thread has been started, the tool Q in the side head is started on the facing of the part of the web indicated by the arrow in the illustration. This cut being short is over before there can be any interference with the bar and the tool is drawn back and started on the outside turning of the rim. Speed, of course, must be set for the larger diameter and, as this surface is somewhat shorter than the hub portion, it is obvious that it will be completed before the other. The undercutting tool D is now set at work in underfacing the rim and some care may be necessary at this point to avoid running into the face of the jaws. It is not essential, however, to completely finish this face as the second setting will remove some of the stock.

The main head tool K is next used to face the end of the hub and the tool S in the side head is started on the relieved portion of the web. The finish facing of the end of the hub is done at the same time by the tool M in the main head turret. The boring bar G now begins its work on the recessed hole and, while this process is going on, the tool E in the side head is successively used to finish the thread diameter, the hub itself, the finished surfaces on the web, the outside of the rim and the under face of the rim. Coarse feeds are used for these operations with a very small removal of stock, two cuts being necessary to bring it down to the correct sizes. The rubbing effect or drag of this

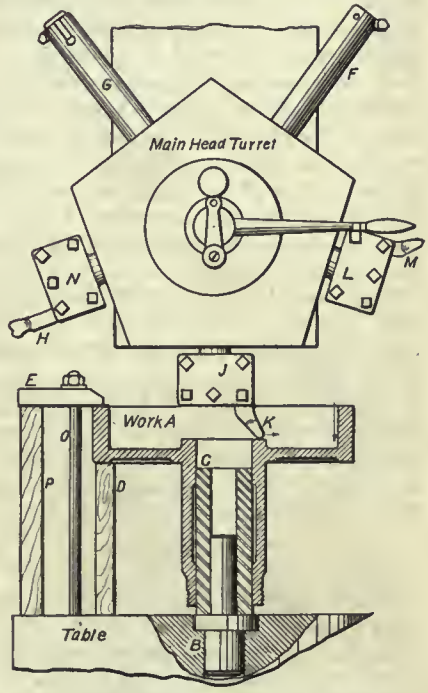

FIG. 6. SECOND SETTING OF PULLEY, SHOWING USE OF LOCATING BUSHING.

wide-faced tool produces an excellent finish. The slip cutter for the reaming bar now finishes the hole leaving noth-

ing more remaining in this setting but the chasing of the thread.

The thread chasing attachment is thrown into gear and the turret indexed until the bar H is in position for the threading operation. This bar is dovetailed across the end to receive the threading tool O which is adjustable. A split in the bar permits the ready clamping of the tool through the screw P which acts as a binder. Several passes are necessary to produce the thread, a special arrangement of the mechanism permitting the rapid power traverse to be used in returning the tool after each cut and picking up the thread without trouble, thus avoiding considerable lost time and the necessity of reversing the machine.

Figure 6 shows the tooling for the second setting of the work A and also the method of setting up by means of a locating bushing on a central plug B. The patternmaker is called on for assistance in this setting and he cuts out some blocking as shown at D and P, three pieces of each kind of equal length. The mark rests on the three pieces D while the clamps E are supported at their outer ends by the blocks P. The long tee-bolts O are used in the table tee-slots for clamping the work firmly in position. It is then indicated in order to make sure that no distortion has taken place during the setting of the clamps.

Another holder N is placed in the main head turret for this setting of the work, this being shown at N with a roughing tool H in position for roughing out the web portion of the casting. The first operation in this setting is that of rough facing the hub and boring the inside of the rim with the tool K used in a previous setting. The second operation consists of facing the web with the tool H, a roughing operation being all that is required. The final finishing of the end of the hub and the inside of the rim is done by the tool M used in the first setting. Correct height from the end of the hub to the face of the rim is easily obtained by setting the tool on the finished rim and then dropping the head the required distance as indicated by the graduations on the hand wheels. It will be noted that the side head is not used at all in this setting of the work.

Escher Wyss & Co., of Montreal, have been awarded a contract by the city of Saskatoon for one four-million-gallon motor driven centrifugal pump to operate against a head of 162 feet, and for one four-million-gallon motor driven centrifugal pump to operate against a head of 40 feet. The motors and switchgear will be made by the Canadian General Electric Co.

Fast Work on Large Centrifugal Pump Castings

By John H. Eastham

The advantages to be gained by the judicious distribution of a bonus among all those directly connected with the production of a piece of work are here well illustrated. The job is one that calls for ingenuity and mechanical ability from a combination of operators.

TO insure early delivery of a manufactured product, a bonus was offered the foundry for each day under, and a penalty imposed for each day over a

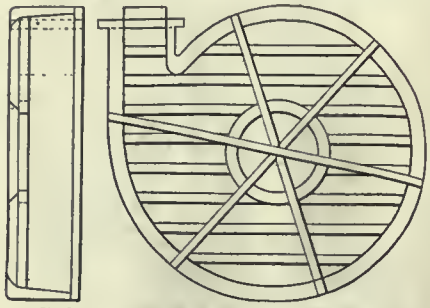

FIG. 1—REVERSIBLE SKELETON PATTERN.

contract time, for the completion of the two sets of centrifugal pump castings of unusually large size. The bonus though not large, was sufficient to stimulate an amount of energy, thought and co-operation that resulted in the finishing of the job in remarkably short order.

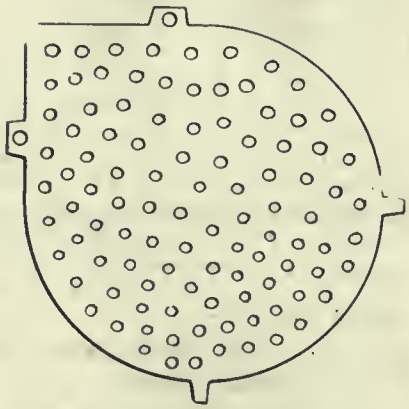

FIG. 2—REVERSIBLE DRIER PLATE.

A pattern of skeleton type shown in Fig. 1 was so fastened together with screws as to permit the cross ribs to be turned over to the opposite side of the flange, thus rights and lefts were easily moulded from the one pattern. The adoption of this plan saved more than a week in the pattern shop. A core frame of similar skeleton design, also reversible, was built, so as to allow moulding and core-making to proceed simultaneously; two shifts of twelve hours each being employed in the foundry on both operations.

As the heavy main core, measuring nine feet in diameter by fifteen inches deep, required at least two nights' drying, the plate shown at Fig. 2 was first cast, both faces being made as smooth as open sand moulding would permit. Right and left-hand core-making would have entailed either the use of each side of the driers or extra plates at additional cost. To bring the time and cost of production down to the minimum, the method of moulding employed was as follows:

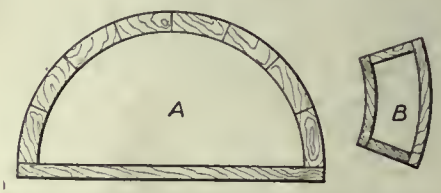

FIG. 3—SKELETON CORE BOXES FOR MAIN CORE AND FLANGE COVER CORE.

A pit twelve inches deeper than the casting's lowest point at strengthening ribs and flanges was dug, and on this a coke bed laid to facilitate venting in the usual way. A bed was next struck off above this at the full depth of pattern. The pattern was next lowered into place and set dead level. The runners were then bedded in, and mould rammed up to the floor level or parting line by one set of moulders.

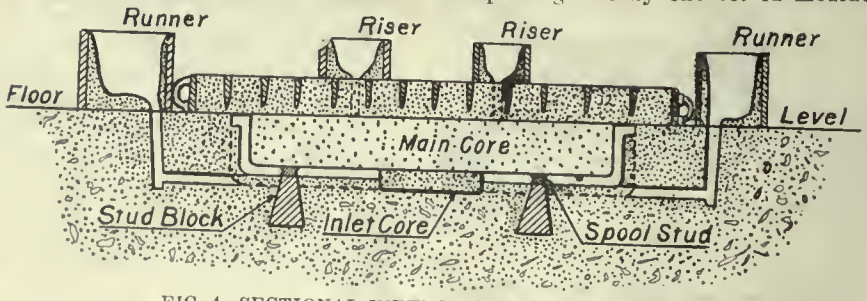

FIG. 4—SECTIONAL VIEW OF COMPLETED MOULD.

During this time, a moulder and helper swept up another bed and on this rammed up the twelve-foot square cope required to cover the mould and core.

The pattern was now cleaned out by means of short strickles cut to fit between the ribs and to give the correct depth. It was drawn out, the mould finished, well nailed at all fillets and corners, blackwashed and fired by the same set of men. In the meantime another gang started to ram up a second mould of same hand before changing pattern over.

When dry, the mould was cleared of ashes, and the intake cores placed in position, a view of this skeleton half core box being shown at A, Fig. 3. Six spool studs 1¼ in. deep were next placed on the blocks in the bed as shown in the sketch of finished mould, Fig. 4. It now remained to set the body core, place the cope, add the weights, prepare pouring basins and pour the piece with a tough semi-steel mixture suitable to withstand the heavy pressure thrown on a pump casing of this kind.

In moulding the second and ensuing pieces, a change of method was necessary owing to the amount of floor space covered by the use of two pits, and the twelve-foot bed required on which to ram up the cope. A core box, 1 in. deep, so as to fit easily under the box bars and of shape, shown at B, Fig. 3, was next made. Thirty-six cores, four of them bored to allow of risers, were required to cover the flange after the main core was lowered into place. The empty cope was then lowered over the mould and cores, and was rammed up in that position, all joints being first stuffed

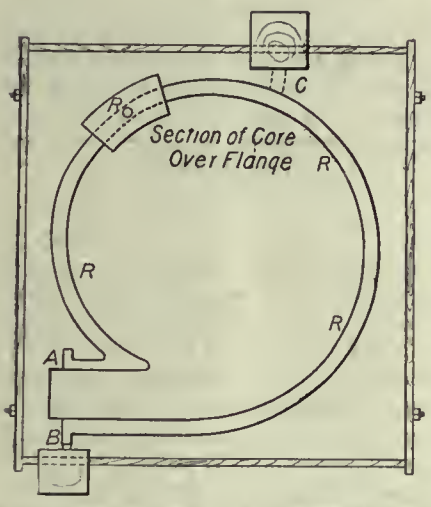

FIG. 5—PLAN VIEW OF CLOSED MOULD.

with waste, to prevent any possibility of sand working through; its removal afterwards being obviously impossible.

As the bed used to ram up the cope was not now required, considerable room was saved, which allowed of the third mould being ready to receive the flask as soon as the second was cast, and the fourth by the time the third was poured.

Fig. 5, is a plan view of the closed mould, showing one section of cover core with riser hole R bored. The position of the runners A, B, and C, and pouring basins are also indicated while in Fig. 6 is shown the style of grating used in the body cores. One and a half inches clearance was left all round between this core iron and casting to facili-

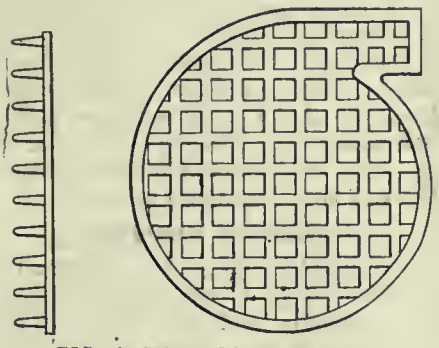

FIG. 6—MAIN CORE GRATING.

tate its removal and prevent risk of breaking the casting during contraction.

Little trouble was experienced in finishing the job in a very satisfactory way well within the specified time and to the credit of all concerned.

MODERN LOCOMOTIVES.

By Henry Bartlett.

TWENTY years ago the express passenger engine was of the eight-wheel type with 18 x 24-in. cylinders, a 58-in. boiler carrying 160 lb. of steam, a grate area of 19 sq. ft., a tractive power of 15,300 lb., and a weight in working order of about 50 tons. Since that time larger eight-wheel passenger engines have been built, then the Atlantic type of locomotive, and now the Pacific type has been reached as the standard express locomotive on many railroads. The standard Pacific type express locomotive of the Boston and Maine Railroad has 22 x 28-in. cylinders, a 68-in. boiler carrying 200 lb. of steam, a grate area of 53.2 sq. ft., a tractive power of 31,600 lb., and a weight in working order of 235,000 lb.

These locomotives have also many improvements, including a superheater, piston vales, Walschaert valve gear, a brick arch, pneumatically operated fire-door, flexible stay bolts, extended use of cast steel, a design of trailing truck permitting the use of a deep wide fire-box.

They show an increase of 83 per cent. in capacity, and at the same time an increase of 80 per cent. in weight over the standard of twenty years ago. This increase in weight in about the same proportion as the power may perhaps suggest a lack of refinement in detail, but upon investigation is will be seen that this apparent disparity does not actually exist, as one of the most characteristic improvements in locomotive design has been the introduction of the trailing truck which makes it possible to obtain ample heating surface and larger grate area, thus enabling the locomotive to deliver its rated tractive power under all service conditions, and to do it with the consumption of less fuel.

Passenger Service Locomotives.

Local conditions have developed larger passenger engines on some other roads, and the introduction of heavier steel cars will require still greater power to handle them. An example is the famous No. 999 on the New York Central Railroad, with which was inaugurated the Empire State express at the time of the Chicago Exposition, and in comparison with this the Pacific type engine which now handles the Twentieth Century Limited between New York and Chicago. In these engines, the increase of 100 per cent. in tractive power and 118 per cent. in weight is a mute testimony to the rapid growth in weight of rolling stock as well as in passenger traffic.

An interesting feature of the old No. 999 locomotive was the water table extending the full length and width inside the fire-box as a substitute brick arch, and there can be no doubt but that the increased heating surface and circulation obtained in this way was an important factor in the phenomenal success of that engine, although to-day we are obtaining similar results in an easier way with the brick arch supported on water tubes.

The development of twenty years on the Rock Island Railroad has been to the use of the mountain type of locomotive, the latter being designed to haul heavy passenger trains over 1 per cent. grade at moderate speeds and yet be capable of attaining speed of from 50 to 60 miles per hour on levels. The increase in tractive power here is 138 per cent. and in weight 156 per cent. One of the best examples of modern locomotive design is a locomotive built by the American Locomotive Co. for the Pennsylvania Railroad for testing out purposes. This locomotive, which is of the Pacific type, has been given a long try-out at the testing plant at Altoona, at speeds ranging up to 85 miles per hour. Notwithstanding the immense power and weight of this engine, it has delivered a horse-power hour on 16.4 lb. of water and 2.66 lb. of coal, establishing a record in this respect; the best performance of twenty years ago was a horse-power hour on about 27 lb. of water and 4 lb. of coal. This remarkable locomotive showed an evaporation of 6,500 gallons of water per hour, and develops a draft in front of the diaphragm of 19.6 in. of water. The maximum coal consumption in these tests was 9,700 lb. (4.8 tons) per hour,

which was accomplished with stoker firing; in this manner about 50 per cent. greater boiler capacity was obtained than would have been possible with hand firing.

Freight Service Locomotives.

Twenty years ago, ten-wheel locomotives were in common use for freight service. The standard freight engines on the Boston and Maine Railroad at that time had 19 x 26-in. cylinders, a 58-in. boiler, carrying 150 lb. of steam, a grate area of 19.5 sq. ft., a tractive power of 20,600 lb., and a weight in working order of 116,000 lb. The present standard freight engine of this road is of the consolidation type, with 24 x 30-in. cylinders, a 68-in. boiler, carrying 180 lb. of steam, a grate area of 53.5 sq. ft., a tractive power of 43,400 lb., and a weight in working order of 210,500 lb. This engine has also the latest features of design, such as superheater, Walschaert valve gear, piston valves, a brick arch, pneumatic fire-door opener, etc., the increase in this class of engines being 90 per cent. in power and 81 per cent. in weight.

The transportation of freight is the most important problem that the majority of railroads have to consider, as it produces the largest part of their gross revenue and consumes the greatest proportion of their operating expenses. In considering the best type of locomotives we are confronted with a great variety of requirements which must be met in conducting this traffic. The consolidation type is giving good service where traffic conditions are suited to its limitations, that is, low or medium speed; as a type, it carries a greater proportion of weight on its driving wheels than any other road engine, and in that respect is the most logical type to select for the above mentioned class of traffic.

As the demand came for more rapid movement of freight trains, more powerful consolidations with larger driving wheels were developed, but they did not fill the requirements as expected because of lack of boiler capacity to furnish steam at the higher speed, and also the fact that the larger driving wheels had restricted the depth of the fire-box to such an extent that a large part of the heating surface was valueless. This has resulted in the development of what is called the Mikado type of engine, which is really a consolidation with a trailing truck which permits the application of a boiler large enough to furnish steam for the maximum requirements, and at the same time give ample room for a fire-box of the requisite area and depth. This type is the latest word as a fast freight locomotive, a large number having been built in the last year or two.

The Mallet type or articulated locomotive has made it possible for many roads to increase greatly the tonnage over a division on which a short heavy grade absolutely limits the train load to a fraction of what could be hauled over the remainder of the division, and where it is too expensive to reduce the grade. Some enormous Mallet locomotives have been built of recent years, one being tested out by the Pennsylvania Railroad, which has evaporated 71,000 lb. of water and consumes 15,000 lb. of fuel per hour; in this engine both sets of cylinders are simple, whereas usually Mallet locomotives are of the compound type. The fuel consumed at the above rate was 86 per cent. of two consolidation locomotives of equal aggregate power.

Superheater Equipment.

The greatest advance in locomotive development in recent years has been the perfection and application of the high temperature superheater. Although introduced extensively only a little over two years ago, it has proved its value so undoubtedly that to-day there are over 7,000 locomotives with superheaters. This device makes it possible to reduce very greatly the amount of fuel consumed, and what is fully as important also, offers a method of obtaining power without exceeding the capacity of the fireman. Among the many attempts that have been made to improve and insure complete combustion, the Gaines fire-box and combusting chamber is an example. In this device, a large volume of heated air is introduced into the fire-box through tuyeres in the vertical wall which materially improves combustion. An important advantage of this type of fire-box is the means it offers of getting ample depth above the grate in designs with shallow throat sheets.

From a paper presented in Boston before a joint meeting of the A.S.M.E., the Boston Society of Civil Engineers, and the American Institute of Electrical Engineers, 1914.

PROPOSED ENGINEERING AUTHORITY

By W. J. Dick.

IN Western Canada there are usually a number of coal seams quite close together, and, should the lower seams be the more desirable with regard to quality and ease of working, there is nothing to prevent the operator from mining them first. In fact, this practice is now being followed in a number of cases in the West. As a result, caving of the measures will render it difficult, and, in many cases, impossible, to recover the coal from the upper seams. Owing to the wide distribution of coal, and the granting of leases to anyone desiring to mine it, the operator who looks to the future and mines the coal in a systematic manner, at an additional cost to himself, has to compete with the operator who takes the easiest available coal. There is, therefore, little encouragement to use other than wasteful methods.

A case came under notice where, owing to a great demand for coal, the directors instructed a mine manager to produce an output greater than the development work justified. The mine manager was forced, against his better judgment, to obtain the coal wherever he could. Some pillars were extracted and others were reduced to such dimensions that they were not able to bear the weight of the superincumbent strata. As a consequence, there was a squeeze, and to-day the mine is badly wrecked and much coal has been lost. In this case, the opinion of an engineering authority would have stood between the mine manager and the directors of the company.

It is suggested that an engineering authority be appointed by the Dominion Government to approve of the methods to be employed at all mines operated under a Dominion Government lease, and that the chief inspector of mines of each province be associated with the engineering authority in so far as matters relating to the operation of mines in that province are concerned. It would also be the duty of such authority to investigate all applications for leasing of coal lands and to determine the conditions under which such leases should be granted.

It is of interest to note, in this connection, that the Dominion Government exercises a stricter supervision over the leasing of water powers than that suggested with regard to coal; yet coal is just as important as water power, and, unlike it, can be exhausted.

Steam Raising Development.—A demonstration of the possibility of steam raising by the combustion of liquid fuel directly in contact with water has been made in Bremen, Germany. An apparatus consisting of a cylindrical boiler, provided with a number of pockets isolated and drained by suitable valves and drain cocks, was used. Each of these pockets contains an oil burner, with a pilot burner, by means of which the main burner can at starting be sufficiently heated to effect complete combustion of the oil. When the main burners are well alight, water from the boiler is permitted to flow into the previously drained pockets, and the circulation of heated water commences, the products of combustion as well as the steam generated being used as a source of power in a steam engine.

TRAINING THE APPRENTICE.

By J. E. Cooley.

ALL the wonderful things seen and done nowadays have become what they are, because mechanical ability with the aid of machinery and tools has made them so. In a word, progress is dependent on the machinist, so when a boy or young man comes into a factory to learn the machinist trade he takes up the most progressive calling and genius-making craft in existence, and industry gains a valuable asset besides. Whether the apprentice takes to this calling and "makes good," and at the end when out of his time can turn a neat job and shows a mechanical bent of mind, will depend mostly on the care and attention given him at the beginning.

Gaining His Confidence.

There are certain rules to be taught him by his instructors, certain methods and routine for him to follow in order to advance, but the chief and most important thing to do at first, and which will be of value to him later, is to gain his absolute confidence and to look out for his safety and welfare at all times. When you receive your introduction to him, and one side of his cheek is not bulged out with tobacco, you have a good chance to keep him from using it. If he uses profane words within your hearing, you can easily teach him that good workmanship is dependent on clean words and clean habits, as well as skill.

Attending to His Welfare.

While his confidence is not gained all at once, but must be acquired, his welfare can be taken in hand the moment of starting. Since the slogan of the present mechanical era is "Safety First," the apprentice is good material to work on. The first thing to do in this line will be to take a glance at his shop clothing and see if he has his "harness" on right. Not that he may have his overalls on, with the back end towards the front, but to see that they are buttoned on the sides; the straps tucked in under the buckles; the jumper on the inside of the overalls and buttoned up; his sleeves, if rolled up, properly done so; and his shoe-strings tucked in the top of his shoes. It is unsafe for a beginner to wear an apron. While it makes him appear like a toolmaker, of course, his safety is of more consequence than his appearance. Running machinery has a peculiar habit of reaching out and catching hold of aprons, especially when these are worn by young apprentices.

The first two or three months may be considered the danger period of a youth's time serving, and after this, if he has not performed any daring feats and been put on the disabled list, he can then be trusted to take care of himself, and the time formerly given in watching out for his safety can be used looking to the quality of his workmanship instead.

Instilling Attention to His Work.

It is found that at the beginning of each young worker's mechanical career there are certain characteristics that crop out in the way of prowess or speed, that only a vigilant eye can expect to hold in check. If he is working on a milling machine, the operation of running the carriage back each time will pall on him, and to break the monotony he will grab hold of the hand-wheel and run the carriage back and forth several times with lightning speed, which exercise is good for him, but bad for the worm and gear under the carriage. If the work he is doing requires a long feed he will need strenuous watching. If there is anything around him to attract his attention his imagination will be sure to get to working elsewhere than at his machine. A four-wheel truck standing idle near him would be just the thing for him to start something. For soon you will hear a rumbling noise from far down the distant end of the room, and coming towards you at full speed you will see that somehow he has started the truck in motion, jumped on it, and is using the truck-handle for a steering-wheel. This is all similar to the way but a few short years ago he rode in a little wagon of his own, on whose sides were painted in glaring colors the word "Flyer."

Remember an apprentice never thinks of the consequences when he starts to do something like the above, so that when he is pulled out from under the bench, or part of his clothing is extricated from between two gears, in either of which location his exhibition will surely have landed him, it will be the "psychological moment" to instruct him not alone in the rudiments of "safety," but to let well enough alone.

Discourage Exhibitions of Strength.

You will notice that after an apprentice takes hold of a shipper-handle a few times to start a machine he soon acquires the habit of slamming it forward with force enough to almost break it, the noise from this often causing those working near him to run for their safety. It will not be necessary to put up a forged steel shipper-handle purposely for him, for he can be led to see that this kind of "push" will be of more benefit if applied to the work in hand.

Care should be given apprentices to see that they do not go to extremes in using their strength in tightening down or pulling against anything, as they are liable to a strain or rupture. An apprentice is sometimes disappointed when denied the privilege of wrenching his side in pulling down on a vise-handle. Sometimes he uses a hammer or babbit to tighten up the vise. This secures the work alright but forms a nice radial curve on the vise-handle for someone to straighten out afterwards. The apprentice should be told not to leave a vise with work fastened in it, especially, if it is a tapping job into which are attached a tap and wrench, for these are liable to get knocked over onto the floor and break the tap, and your own heart, nearly, if you happen to be a witness of a catastrophe of this kind.

One of the "stunts" he often pulls off is to grab hold of an unright belt while it is running, to try and hold it back for a second or two. Sometimes he succeeds in doing this, and also in causing the overhead driving belt to slip from the pulley. Such practices as this should be early discovered and also discouraged. In counseling him against it, he can be told that the engine has enough to do in driving the machinery, let alone having the double task of pulling against the strength of an apprentice.

Change of Work Beneficial.

Changing his work frequently will be of benefit to him and will keep him more interested in it, and less in his muscular development or the clock on the wall. In his work he should be early taught that well-doing is preferable to quantity and quickness in its output. Equally important also it is to let him see you are interested in the outcome of his apprenticeship. This is done by teaching him kinks and rules in regard to thoroughness in good workmanship, to expend less energy than needed and to eliminate as much as possible lost motion. These things when taught him will make each new task he handles an attractive proposition.

As his confidence is gained, his loyalty to his work and employer will increase. The confidence to be had from the apprentice is going to be equal to the amount put in him. If occasionally he is

given an intricate piece of work to do, it will flatter him and help strengthen the confidence in himself. Whatever work he may occasionally spoil, he need not be dealt with too harshly even though that has been the common practice in times gone by, because he is going to learn, and "come back" by his mistakes and spoilt work; and he will do so quicker by coaching and encouragement, than by scolding and abusive language.

The successful training of the apprentice is dependent on the amount of care, interest and attention given him. As his heart becomes engrossed in his work a new world gradually opens up to him; he sees new possibilities from a mechanical standpoint; it awakens in him the ability to see into all sorts and kinds of mechanisms, and the profession itself develops his character and makes a man of him. He wants only to be treated fairly and nobly. He looks first, last, and always for a square deal, and these, coupled with confidence and a respect for him, place in your hands the making of a master-mechanic, a future manufacturer, and who knows, perhaps, a great genius.

SHOP TALK TO MACHINISTS.*

By Chas. Stelzle.

WHEN I was in the machine shop I could always tell, without looking at the signature, who made the particular drawing from which I was working. There was something peculiar about the lines and the curves which were characteristic of the draughtsman who did the job. A "Reid" drawing was very different from a "Schmidt" drawing, even though the general subject was the same. It was the same way with a "chipping" job—the marks of the chisel revealed the identity of the machinist who was responsible for it. So it was with file-marks and polishing jobs—the name of the mechanic stood out as plainly as though it were written there in acid.

Every fellow puts something of his own personality into his daily work. He does it in spite of himself, and the way that he does his work reveals his true character. You can always judge of a man by the job that he turns out. Talk about somebody keeping a record somewhere off in heaven of the deeds done on earth! Every fellow is writing his own record with hammer and chisel, with file and pen.

Well-defined Principles to Guide.

One draughtsman I have in mind was given a good deal of liberty in the way that he worked out the details of his drawing. He was original in some very important particulars. You know there's a lot of difference between machines made in this country and those made in some European countries. There's a difference in weight and in shape and in general appearance even in machines that turn out the same product. It's a question of taste and judgment as to detail.

This is true of every successful machine that was ever designed or constructed. It is the same with the plans for your life. You are given considerable liberty as to the details of your occupation; but you can't build up a successful life without obeying the laws of honor and integrity. Your lives are different one from the other—no two of you look alike or act alike in even some of the most important things; but every man whose life is going to count for much must obey the laws of the Almighty.

I had a chum when I was in the machine shop; he was a patternmarker apprentice. I used to eat my lunch with him, and I was always interested in the jobs that he was turning out, because I knew that soon I'd handle the same job, but in a different form. He was making the wooden pattern; I would handle the cast product. There was one thing about his job that always fascinated me—he worked from a "patternmaker's rule."

Now, you know that a patternmaker's rule is different from a machinist's rule; if the casting is to be made of iron, the special rule that he uses is an eighth or three-sixteenths of an inch longer per foot than the machinist's rule, and if the casting is to be made of brass, the rule is about a quarter of an inch longer per foot than the standard scale. This is so because when the pattern is placed in the sand by the molder, and the hot metal is poured in, it shrinks when it cools off just about in proportion to the difference between the patternmaker's rule and the machinist's standard rule.

A Vision All Important.

Beethoven tells us that his beautiful symphony is but an echo of the music he heard in his dream. It lost its divinest charm when he transferred it to the manuscript. It may be easier to build castles in the air than to construct huts upon the ground, but the man who never has a vision—an ideal—can't even build a hut that's worth while. The dreamer has his place in the world's work, for every machine and every great enterprise was dreamed out before it was worked out. A wise philosopher once wrote: "Hitch your wagon to a star." Now that's mighty good advice, so long as you manage to keep the wheels on the ground; but the thought that the philosopher had in mind was that we were to have high ideals—large patterns—because in this practical, everyday world these high ideals are sure to suffer when they are subjected to the commonplace duties of life.

Influence of Our Surroundings

There was a big, fat machinist in my department. He must have overweighed three hundred pounds. Now, you'd think that this big German—his name was Miller—would move around most ponderously; but not much. He ran a little speed lathe that spun around at lightning speed, and to keep pace with that machine Miller had to hustle.

There was another fellow down in the basement who ran a big six-foot lathe. He was a fine, athletic-looking chap. His name was Thompson. You'd expect this man to be a sprinter in his movements; but he wasn't. The reason of it was that his great, slow-revolving lathe had set his pace for life. Sometimes it seemed that his lathe scarcely moved; and so Thompson didn't have to move very fast while he was working. Neither did he move very fast when he wasn't working.

Did you ever notice when a man began to use a hammer at one end of the shop and set up a steady, rhythmic tap-tap-tap, and then some other fellow began to use a hammer within the sound of the first one, that the second chap kept exact time with the other? You see, we are influenced on every side. By the men that we work with and by the very machines of which we are supposed to be masters—actually, the latter frequently master us. There's a lot in the statement that some men are chained to the machine they run.

Big Ideals Necessary.

Now, to overcome these influences when they are bad we need to have big ideals. There are some working men whose motto in life is simply: "Meat, malt, and mattress"—eat, drink, and sleep. Mighty poor ideal; don't you think so? You apprentices and young mechanics, in particular, don't ever permit yourselves to degenerate into commonplace working men. I mean men who become careless of their manners and their dress, and who think of no higher things in life than to drift into the saloon at the end of the day's work, and then go home, half drowsy, and make themselves a nuisance to their wives and children, who may be struggling to maintain some degree of culture and refinement.

We hear a lot these days about "anti-poverty societies," but, take it from me, no society can do for a man what he will not try to do for himself. The successful man does not look "out" for opportunities; he looks "in," for that's where most of the chances come from.

*From "The Outlook."

Arithmetic for the Machinist and Workshop Operative

By J. H. Rodgers

With the further development of this course in arithmetic. it will be found by those who have followed the introductory lessone and profited by them that the various practical applications resulting from the succeeding lessons will be easily observed and their time and labor-saving features so appreciated as to be adopted at every available opportunity.

TAPER WORK.

OFTEN work comes to the milling machine to be shaped on the ends so that the corners or edges will retain or form a specified angle; for instance, pointed drills, square centers, etc. In charts 28 and 29, are shown four cuts of pointed centers, which, when used for centering or rounting, give 60 degrees.

In the triangular point, chart 28, it can he clearly shown by a diagram that the distance d—c = one-half the distance d—a, or d—c = ½ inch.

To find length o—d, use formula:—

Side adjacent = hypotenuse × cosine = 2 × cosine of 30 deg. = 2 × .86603 =1.73206 in.

To find angle (c o d) of inclination necessary for milling the flat, use formula

$$\text{Tangent} = \frac{\text{side opposite}}{\text{side adjacent}} = \frac{.5}{1.732} = .28868.$$

Looking in chart 15 for corresponding angle, we find it lies between 16 deg. and 17 deg.

To find the fraction of the degree, use formula at foot of chart 15.

$$a_1^\circ = a^\circ + \left\{\frac{d_1}{d} \times 60\right\}^{min}$$

$$a^\circ + \left\{\frac{.00193}{.01898} \times 60\right\}$$

$= a^\circ + b^1 = 16^\circ\ 6' =$ angle (c o d).

In the sqnare point, chart 28, the length d—c can be found from formula, chart 12, where

$$\text{side} = \frac{\text{diagonal}}{1.414} = \frac{2}{1.414} = 1.414.$$

Then length d—c = 1.414÷2=.707 in.

Again, by formula,

Side adjacent = hypotenuse × cosine =1×.70711=.707 inches.

To find angle (c o d) of inclination use formula

$$\text{Tangent} = \frac{\text{side opposite}}{\text{side adjacent}} = \frac{.707}{1.732} = .40819$$

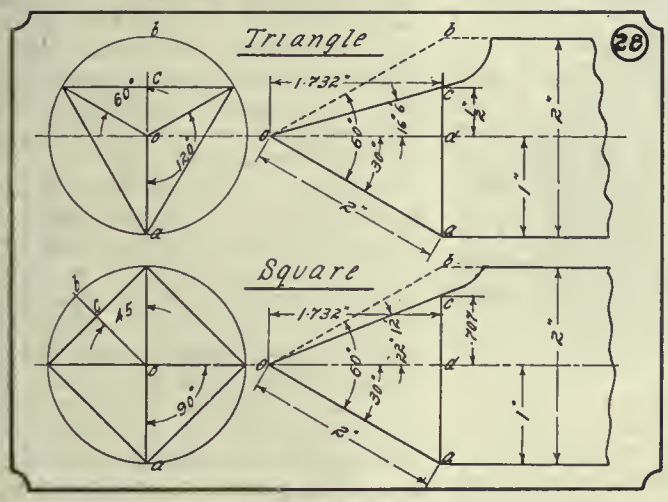
From chart 15 we find corresponding angle to be 22° 12′=angle (c o d).

In the pentagon point, chart 29, the length d—c = the cosine of the angle 36° = .80902 inches; then angle (c o d) is found by formula,

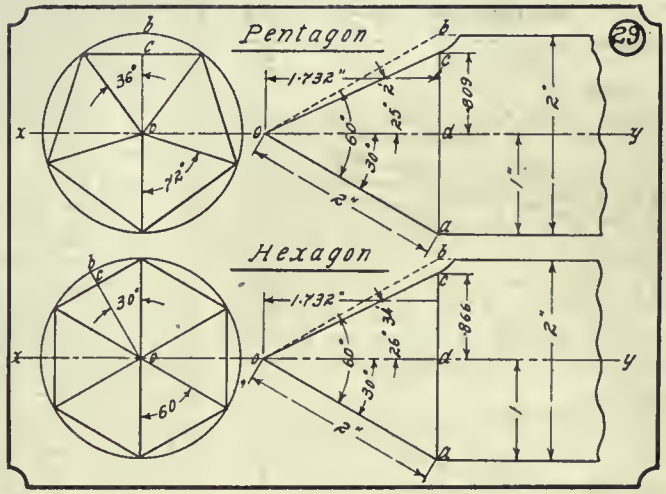
$$\text{Tangent} = \frac{\text{side opposite}}{\text{side adjacent}} = \frac{.80902}{1.732} = .46710.$$

From chart 15, corresponding angle =25° 2′=angle (c o d).

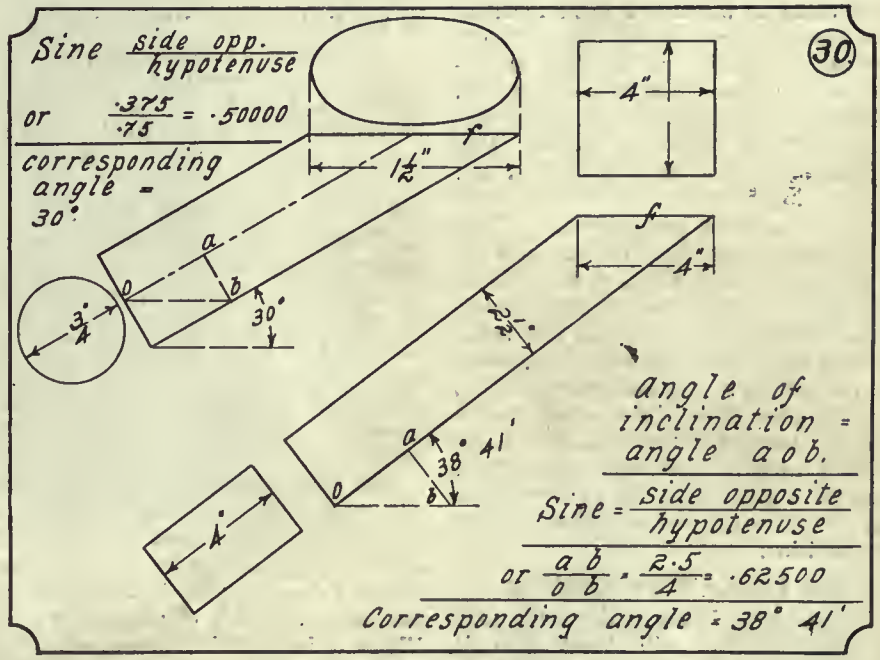
In the hexagon point, the length d—c



ARITHMETIC CHART 28.



ARITHMETIC CHART 29.



ARITHMETIC CHART 30.

= cosine of 30° = .86603 inches, then angle c o d is found by formula,

$$\text{Tangent} = \frac{\text{side opposite}}{\text{side adjacent}} = \frac{.86603}{1.732} =$$

.50000, and corresponding angle from chart 15 = 26° 34′ = angle (c o d).

In chart 30 are shown sketches of a couple of interesting milling problems. A piece of ¾-in. round stock is required to be milled so that the face (f) will form an ellipse whose major axis measures 1½ in.

From the nature of the question it will be seen that the length o—b (one-half the major axis) will measure ¾ inch. Then, to find angle (a o b), use formula,

$$\text{sine} = \frac{\text{side opposite}}{\text{hypotenuse}} = \frac{a—b}{o—b} = \frac{.375}{.75}$$

= .50000.

From chart 15, corresponding angle = 30°.

Again an oblong block of steel 2½ in. x 4 in. requires milling so that the face (f) will be a square measuring 4 in. on a side.

The length o—b will equal the length of side or 4 in., and the length a—b will be the short side of oblong, or 2½ in. Then angle (a o b) will be found from formula,

$$\text{sine} = \frac{\text{side opposite}}{\text{hypotenuse}} = \frac{a—b}{o—b} = \frac{2.5}{4}$$

= .62500, and corresponding angle = 38° 41′ = angle a o b.

IRON IN BRASS.

By M. Dings.

That iron is a dangerous impurity in brass and copper alloys is now a well established fact. Many attempts have been made to produce a good inexpensive bronze by combining iron with copper and its alloys, but all such experiments have given unsatisfactory results. Metallurgical authorities inform us that carbon is the interfering element that prevents the true alloying of iron and copper. All commercial iron or steel contains more or less carbon. Thus, when iron or steel finds its way into the crucible with brass chips, it does not alloy but produces a dangerous mechanical mixture. The iron forms into small nodules and these nodules seem to absorb all the carbon in the surrounding metal, forming themselves into steel harder than the hardest chilled tool steel. These nodules vary in size from a small pin head to a pea, according to how much the metal has ben stirred while in molten condition.

Tool Trouble When Machining.

In machining brass castings, the edge of any steel tool will break when it strikes one of these nodules. This is one of the reasons why the presence of iron in brass castings is dangerous. Thousands of dollars' worth of tools have been ruined, much valuable time has been lost and a great deal of annoyance has been caused by these troublesome nodules. They are especially dangerous to tools in automatic machines. Often the operator does not notice that a tool has been damaged until many good castings have been spoiled by dulled tools or broken dies. In rolling thin brass sheets, the surface of chilled rolls are sometimes dented by the steel nodules in the brass plates. In polished work, wherever the nodules are close to the surfac, rusty spots will appear upon the brass.

Separation Difficulty

It has been fully demonstrated that with the utmost precaution, it is impossible to keep brass chips free from iron and steel. In shops where both brass and steel are machined, the brass chips always contain iron. No matter how carefully the lathes and machine tools are cleaned between operations on different metals, iron dust and small chips left in the crevices of the machines will contaminate the brass chips. Even in places where brass is worked exclusively, more or less iron and steel find their way into the brass chips. When such chips, supposedly free from iron, are treated with a magnetic separator, there is usually found an assortment of nails, screws, rivets, nuts, washers, small drills, broken taps, pieces of fractured tools, wrenches, pocket knives, etc. If any one of such articles happens to be melted in a crucible of brass, bad castings are to be expected.

Numerous fluxes for removing iron from brass have been sold to the trade, but experience has shown that they are of but little value. Where they appear to accomplish the desired purpose, careful analysis shows that the iron does not slag and rise to the top so that it can be skimmed off, as supposed, but when there is less than 2.75 per cent. of iron, it is really driven into the brass, producing a casting of a dark color, and very much harder than it ought to be. If there be more than 2.75 per cent. of iron in the mixture, steel nodules will appear in spite of any soda-ash, sea sand, or other flux of secret compound. Thus the best informed men rely upon magnetic separators as the most effective appliances for removing iron from brass chips.

Just how much iron can be alloyed with copper is not positively known. It is supposed to be about 2.75 per cent., but this alloy cannot be made by direct fusion unless the iron is free from carbon or the carbon is eliminated by a flux. When it is desirable to introduce iron into a bronze, the best practice is to introduce it in the form of a zinc-iron or an iron-manganese alloy. Any excess of iron above the percentage above mentioned produces steel nodules.

Magnetic Separation.

Evidently it is not safe to melt brass and copper chips without first treating them with a reliable magnetic separator. As brass founders and metal refiners come to understand more clearly the necessity of melting only such chips as are absolutely free from iron, they realize that a poor magnetic separator is as unsatisfactory as none at all. Therefore metal men are cautioned to purchase only such magnet machines as have been thoroughly proven. Separators having magnets energized by electric coils are considered much more efficient than the old style machines using permanent steel horse-shoe magnets. The electro-magnets are much more intense and do not weaken with age.

Sometimes too much is expected of a magnetic separator. A good separation of any kind depends largely upon having the mixed material to be separated in proper condition. If the brass chips are greasy, or wet, the finer of them will adhere to the large iron chips and be removed by the magnets. Again, the chips may contain long spirals, or be in such curled form as to cause bad mechanical entanglement, by reason of which some of the brass is lifted with the iron and carried into the iron products. In handling metal worth $200, more or less, per ton, it pays to use common sense and give this separation problem some attention. The iron product is usually only a small part of the original bulk. If it be found to contain too much bronze, it can be quickly re-treated under a different adjustment of the separator so as to recover the brass.

A good separator should have a good feeding hopper so that the metal is brought to the separating point in an even steady flow, but a device designed to feed fine chips should not be expected to work well when the chips contain such things, as rejected castings, kindling wood, wads of paper, wrapping twine and other coarse articles. It is often a good practice to screen the chips through a ½ in. mesh screen before shoveling it into the feeding hopper of a separator.—From a bulletin issued by the Dings Electro-Magnetic Separator Co., Milwaukee, Wis.

The Gurney Scale Co., Hamilton, Ont., have been awarded a contract by the Dominion Government for a track scale 108 feet long. When erected this will be the longest scale in use in Canada, and one of the few scales in the world over 50 feet long.

PROGRESS IN NEW EQUIPMENT

A Record of New and Improved Machinery and Accessories for the Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

WARNER SILENT TUMBLING BARREL.

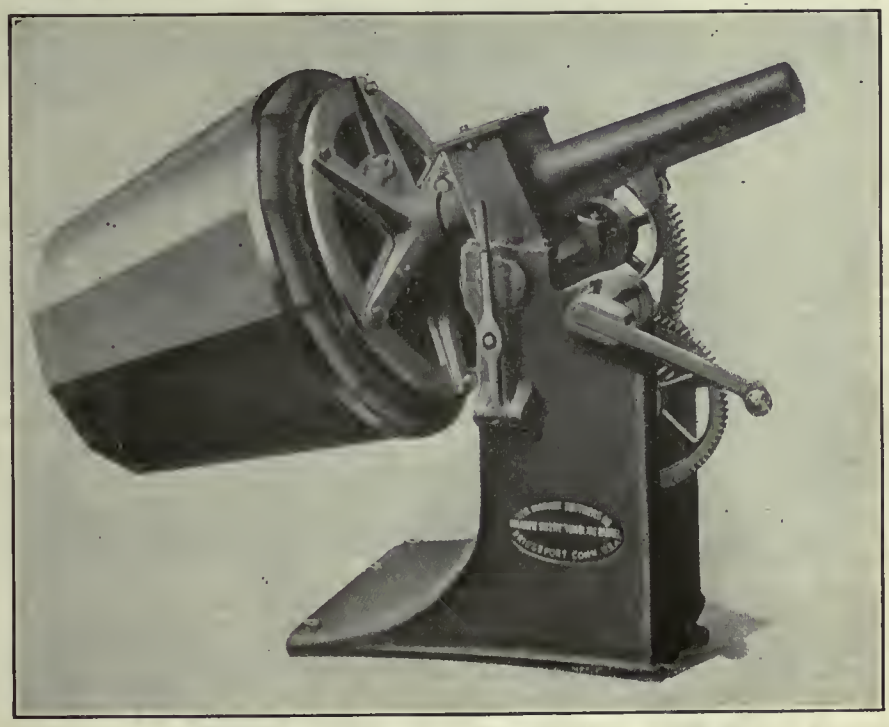
THIS Silent Tumbling Barrel is a product of the Warner Bros. Co., Bridgeport, Conn. The illustrations and description herewith refer to the general constructional and operative features. The drive is by means of a case-hardened steel worm and cast iron gear with cut teeth running in oil, a circumstance which contributes to silent operation and absence of wear of the gears. The driving pulley is equipped with an internal expanding friction clutch, operated by a lever on the same side of the machine as the tilting crank. This eliminates the necessity of going around the machine to start and stop it, and also the danger of shifting belts by hand.

Dust-tight housings enclose the driving pulley and worm and gear mechanisms. This eliminates the wear from dust and grit and adds much to the life of the machine, so much so that machines built three years ago have, we understand, been running continually without overhaul and show no signs of wear.

The revolving the worm and gear in oil in the main housing automatically oils all the bearings in the driving mechanism, thus reducing the care required in keeping the machine properly oiled.

The barrel may be tilted to turn at any position between those shown in cuts, thereby obtaining any degree of tumble for the work. The tilting mechanism has been so designed that the pawl has been eliminated. By a slightly outward motion of the crank, the barrel is unlocked and the machine is cranked in the same manner as other machines but should the operator accidently let go the handle while raising or lowering the barrel, the handle automatically locks the barrel in the position in which it was located when the handle slipped. This makes accidents by whirling handles impossible and at the same time avoids spilling the work on the floor. The barrel load is carried by a ball thrust bearing.

SILENT TUMBLING BARREL. DRIVING SIDE.



SILENT TUMBLING BARREL AT LOWEST TILT. OPERATING SIDE.

Coupled with modern construction and design, interchangeability of parts has been arranged throughout.

For grinding and polishing small stampings, forgings, or castings, the cast iron or brass barrel has replaced the old style steel barrels. The cast barrel is polygonal in shape and gives the articles a more violent tumbling and producing a quicker and better finish than did the smooth, round, sheet-steel barrel.

SWING GATE AND CHECK VALVE APPLICATIONS.

An increasing and promising use for the steam turbine is its application as a secondary or low pressure unit in connection with non-condensing or condensing engines, or, combining with a regenerator, in connection with engines using steam intermittently. At first, the most promising application of the low pressure turbine was to use steam from inefficient non-condensing engines which were found in steel mills and mine-hoists, but its field of employment is now extended to efficient power engines in railway and lighting plants as it has been thoroughly established that the most efficient steam plant to-day consists of a compound unit consisting of a reciprocating engine, acting between boiler pressure and approximately atmospheric pressure, and a low pressure turbine which discharges into a condenser.

It was not until the low pressure turbine had been commercially developed that engineers fully realized the significance of the fact that the available energy per pound of steam, between 150 pounds boiler pressure and 28 inches vacuum was cut practically in halves by the line of atmospheric pressure. Reciprocating engines are incapable of utilizing efficiently the energy below the atmospheric line, because to attain the proper degree of expansion requires an enormous cylinder, the friction within which would consume a large portion of the available energy. The turbine, however, can utilize the energy between 26 and 28 inches of vacuum as effectively as

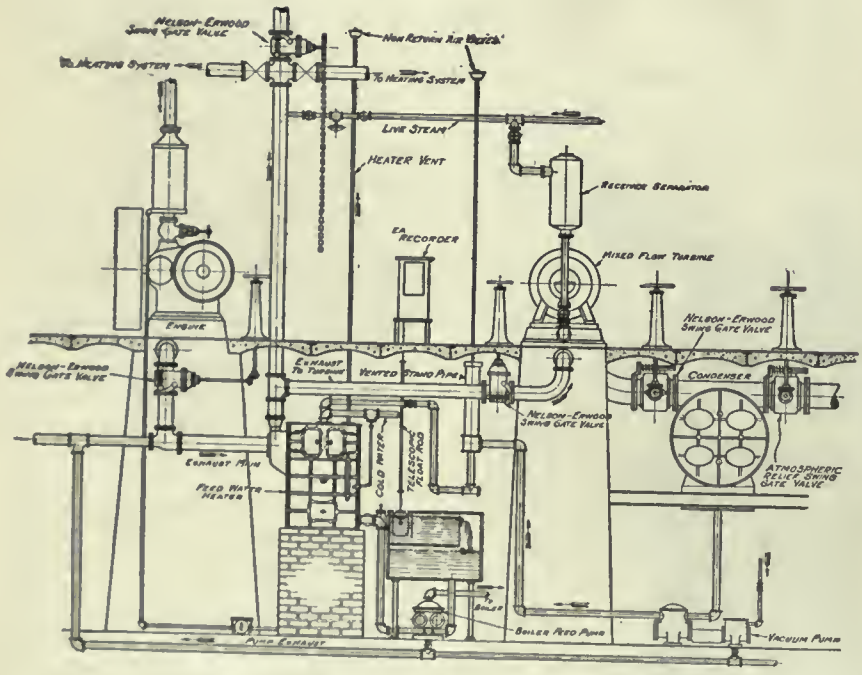
it can utilize the energy between atmospheric pressure and five pounds below. The mixed turbine plant, therefore, gives excellent steam economy over wide ranges of load, it gives considerable elasticity of operation due to the fact that either engine or turbine may be operated separately. Any leakage in the engine due to leaky valves, and improper valve setting is taken care of by utilizing that steam in the turbine; and where exhaust steam is used for heating, the mixed turbine plant allows the required amount of heat to be diverted for heating parposes before the steam enters the turbine. The principal diffieulty which must be solved in the practieal design of mixed-flow turbines, is the method of regulation, so as to allow the use of all the exhaust steam available; after which any deficieney in the low pressure steam supply can be made up by high pressure steam. In order to obtain the proper efficiency of the turbine under the usual operating eonditions, two methods are used.

The first consists of having a turbine so constructed that the high pressure steam is admitted automatically through an auxiliary high-pressure seetion of the turbine. In this case the high pressure steam goes through the high pressure portion of the turbine and after the steam has been expanded to praetically atmospheric pressure, it enters the low pressure part of the turbine in which it expands down to the pressure in the condenser. When low pressure steam is admitted to the turbine it enters the low pressure seetion of the turbine only. When running as a low pressure turbine the high pressure blades will be revolving idly. The seeond method consists in utilizing high and low pressure steam on the same turbine wheels, the steam acting on the same buckets in both eases. The low pressure steam is admitted through one set of nozzles and the high-pressure steam through another set. The nozzles are so designed as to properly expand the steam from either source. Whichever system of steam distribution be used, it is very important that the piping be of proper design, and that both the engine and turbine units be protected by means of the proper safety deviees, so that no damage be done, if the condenser flood, if the wrong valves are manipulated at the wrong time, or if the valves are not operated in their proper order when starting and stopping.

In order to allow the engine and turbine unit to operate safely under all conditions, the Nelson-Erwood Swing Gate and Cheek Valve has been designed and constructed. This acts as a safety valve on any pipe line where it is necessary that the flow through the pipe shall be in one direetion and where disastrous effeets would follow if the steam or condensate were allowed to flow into the engine or turbine in a direction contrary to that for whieh it was designed.

The general arrangement of piping for a mixed turbine and engine plant is shown in the accompanying illustration. When all the steam is used by the operating units, the steam flows from the boiler into the engine, then through the turbine and into the condenser.

If there be not enough exhaust steam coming from the engine to operate the turbine unit, live steam may be admitted to it as shown. If too much exhaust steam be flowing to the turbine, a portion of it may be diverted to flow into the feed water heater. Again a proper amount of exhaust steam may be used from the engine exhaust to supply the heating system when conditions require. Such a combination of piping as shown makes for flexibility of operation under all conditions of serviee.



SWING GATE AND CHECK VALVE APPLICATION.

The general arrangement of piping for a mixed turbine and engine plant is shown in the accompanying illustration. When all the steam is used by the operating units, the steam flows from the boiler into the engine, then through the turbine and into the condenser.

If there be not enough exhaust steam coming from the engine to operate the turbine unit, live steam may be admitted to it as shown. If too much exhaust steam be flowing to the turbine, a portion of it may be diverted to flow into the feed water heater. Again a proper amount of exhaust steam may be used from the engine exhaust to supply the heating system when conditions require. Such a combination of piping as shown makes for flexibility of operation under all conditions of serviee.

The combined swing gate and cheek valves, when placed in their proper positions on the pipe, operate normally as an ordinary stop valve, but in addition they protect the power plant should conditions change without the knowledge of the operator. For instance, if the engine be started, without opening the valve on the exhaust, the swing gate check valve will open automatically at a predetermined back-pressure on the engine and stay open until it is mechanically closed by means of the hand-wheel attached to the valve stem as in ordinary gate valve. When the exhaust steam from the engine is used for the heating system, this swing gate and cheek valve is used on the atmospheric exhaust pipe as a back-pressure valve. With high pressure, any excess of pressure in the turbine, above the back pressure in the engine, is prevented from affecting the latter by the swing gate valve closing automatically. When the pressure on the turbine side decreases, the valve will allow the steam to flow to the turbine in the usual manner. As applied to the condenser piping, the swing-gate valve will prevent flooding of the turbine due to loss of vaeuum and also acts as an atmospheric relief valve.

All of the protective and operating features of the swing gate valve are based upon the fact that it is constructed as a gate and check valve in one, and is capable of performing the functions of either. The checking action of the swing gate is controlled outside of the valve casing, according to the pressure desired, while the further action of the gate is controlled by the hand-wheel, which raises the gate above the valve opening exactly like an ordinary gate valve, thus giving a full unrestricted opening. The face of the gate and the seat ring are flat, both being made of bronze. The valve is always positive in its action, as the seat is constantly cleaned by the raising and lowering of the gate, which wipes or shears off any foreign matter which would otherwise interfere with perfect closing.

The Nelson Valve Co., Philadelphia, Pa., are the designers and builders of this swing gate and check valve.

PLANER WITH ELECTRIC FEED AND AND POWER TRAVERSE.

THE accompanying illustration shows a 72-inch Pond reversing motor planer equipped with electric feed and power traverse for all heads. The design of this planer represents very advanced ideas in planer construction throughout and appears to be the last word in simplicity. Reversing motor drive has eliminated all belts, pulleys, clutches, etc., and now electric feed dispenses with the feed box.

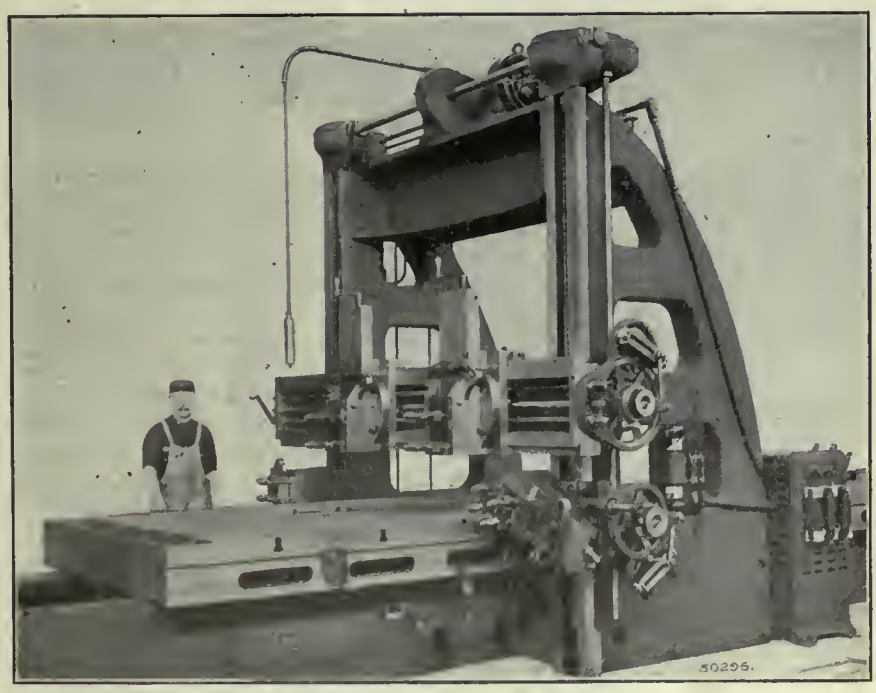
The motor is directly connected to the first driving gear shaft on the back side of the planer, giving the operator free access to the entire control at the front of the machine. There is provided a wide range of cutting and return speeds which may be varied independently of each other while the machine is running by means of the two handwheels on the front of the controller case. The handwheels are equipped with dials graduated for the various speeds. A shaft runs through the bed with levers on either side for control of the table. These levers are same as on the "A" driven planer; hence the operator has no new movements or operations to learn.

A patented pendant switch, carried by a swiveling bracket mounted on the arch, may be moved to any convenient position. By means of this switch the operator can start, stop or reverse the table if the work require him to be in such a position that he cannot readily reach either of the levers on the front and back sides of the bed. At the instant of reversal, the motor through connections in the controller, is disconnected from the line and becomes a powerful dynamic brake, stopping the table at once without drawing any current from the line. To prevent the table from running off the bed and also the breakage of tools or planer, a patented circuit breaker is provided to stop the motor at once by dynamic breaking.

The newest and most novel feature of this planer is the electric feed and rapid power traverse which is provided for all heads. Both the feed and traverse are operated by a separate motor mounted on the arch. This motor is also used for elevating and lowering the cross-rail. The mechanism for the different operations is interlocked in such a way as to prevent accidental engagement of two functions simultaneously. The amount and direction of the feeds for the cross-rail heads can be changed at each end of the rail. The changes of feed for the side heads are made in a similar manner, the feeds for each head being entirely independent of each other and of the cross-rail heads.

The hand adjustment of the side heads is by ratchet crank wrench which is mounted on and moves with the head. All heads have graduated swivels and micrometers on the feed screws. The table is of heavy and very deep box section, without openings through the bottom wall. This gives a very rigid construction and also prevents chips or cutting fluid from reaching the gears or tracks in the bed.

The Niles-Bement-Pond Co., New York, are putting the above machine on the market.



PLANER WITH ELECTRIC FEED AND POWER TRAVERSE.

LABOR ORGANIZATIONS IN CANADA, 1913.

The third annual report on Labor Organization in Canada, covering the year 1913, has been issued by the Department of Labor. At the close of 1913 the numerical strength of organized labor in Canada stood approximately at 176,000, an increase of nearly 16,000 over the figures at the close of 1912. The estimated membership for each of the three years during which reports on organized labor in Canada have been issued has been as follows:

1911	133,132
1912	160,120
1913	175,799

These figures show an increase in membership of over forty thousand during the two years 1912 and 1913, and suggest a quite remarkable development during so brief a period. The figures indicate that the growth of union membership has been fairly distributed as between international bodies and those not international in character. The bulk of Canadian trades union membership is attached to international organizations. Of the total numerical strength of organized labor for 1913, the membership owing allegiance to international organizations reached the large proportions of 149,577, leaving for all other organized bodies a membership of 26,222.

There were in Canada at the close of 1913, just over 2,000 local trade union branches of all classes, 1,792 having international affiliation 199 of a non-international character and 34 independent local bodies. These figures show an increase of 154 in international local union branches, a decrease of 26 in non-international and an increase of six in independent bodies. International organizations having in Canada at the end of 1913 one or more local branches numbered 101, an increase of two during the year. There are thirteen non-international organizing bodies in the Dominion, an increase of three as compared with 1912.

World's Trade Union Membership.

The total trades union membership of the world for 1912 stood at 12,094,490, a slight increase over the number reported for 1911, which was 11,435,498. The union membership during 1912 increased more rapidly in Great Britain than in Germany, the first named country having an increase of over 800,000 and the latter slightly over 256,000, giving Great Britain nearly a half million more of a trades union membership than Germany. The United States stands third, but especially having regard to its much larger population, considerably below Great Britain and Germany.

PRACTICAL EDUCATION FOR MECHANICS.

WHILE it is true that technical schools in Canada have not reached the state of perfection attained by those in some foreign countries, few mechanics make the best use of the advantages at hand. The school education at best can but teach one to understand that which he reads and observes. The man who expects a university, by some mysterious means, to transform him into an engineer, and the youth who depends upon the technical school to add to him the essentials of a master mechanic have both still to meet their keenest disappointments.

The best and most useful practical education is that which is gained by one's personal experience or which is learned from those nearest to practical work. This education is to-day the cheapest, rarest and most paid for. The price is application and self-sacrifice.

Nearly all reputable builders of machinery publish accurate instructions concerning the operation and sphere of usefulness of their machines which are gladly furnished the interested operative without cost. A great number also publish, at considerable expense, a well-edited and illustrated treatise dealing not only with the methods employed in connection with their particular product, but give a comprehensive exposition of the subject in general. These are also sent free upon application. Many manufacturers, among whom may be mentioned the larger makers of gears and gear machinery, publish tests which are sold for the mere cost of publication and mailing.

How often we see a mechanic spending a number of his hard saved dollars for a book which is so technicalized that he cannot understand it and which contains illustrations copied by the author from the manufacturers' publications which he probably obtained for nothing. The hustling mechanic now has his chance and he who makes use of his opportunities will always be the superior of the spoon-fed mechanic of the school.

ADAPTABILITY OF PRODUCTS.

CANADA has no doubt, profited much by the mistakes of United States manufacturers. Their errors of judgment, in many cases, occurred so long ago that, by the time the lessons are applicable to us, we shall have forgotten about them and their discouraging effects. Our trade in exported manufactures, though comparatively large, is in its infancy, and it is at this time that we can best take to heart the lessons so expensively learned by our neighbor.

In manufacturing for export trade, the product must conform not only to natural and legal requirements of the country in which it is to be sold but must also satisfy the precedents, personal opinions and sensibilities of the buyers. In other words the article must be made to satisfy the peculiar local necessities which created the demand for that class of goods and need not meet the demands encountered in the country of its manufacture.

For many years American steel bridge builders were unable to do business in many European countries because of the lack of artistic effect in their structures. Likewise, many opportunities have been lost by failure to add the desired amount and color of paint. The bulk of the Argentine trade in wearing apparel at present goes to Germany and England. In this connection the two largest American manufacturers of collars refused to number their products according to metric standards in use in that country. In another case a certain Western canneryman captured a large part of the English market by making his cases of much heavier lumber than usual so that the consignees could use them for other purposes when empty.

An interesting case in the implement business may be cited. Australians have long used stripper harvesters to deal with the grain crops while the South Americans have become used to the binder. The grain in both cases is eminently suited to the combined operation of reaping and threshing, yet, similar reaper-threshers cannot be sold in these two countries. The farmer of the Antipodes must have a machine with stripper teeth and the American requires one equipped with binder teeth and knife.

INDUSTRIAL NOTABILITIES--No. 43

NOEL GEORGE LAMBERT MARSHALL, the subject of this sketch, was born in London, England, on December 30, 1852, the son of Kenric R. and Charlotte A. Marshall. Following his arrival in Canada in 1856, he was educated in the public schools of Toronto, subsequently, in 1867, entering the employ of L. Coffee & Co., and remaining with them until 1870.

In this latter year he became associated with the C. J. Smith Coal Co., purchasing an interest therein in 1879. Nine years later, in 1888, he, along with Sir William Mackenzie, bought the business outright, changing its name, in 1881, to that of the Standard Fuel Co., which it still retains.

Mr. Marshall is president, the Standard Fuel Co. of Toronto, Ltd.; president, Faramel Co., Ltd., Toronto; president, Magann Air Brake Co.; president, Dominion Automobile Co.; director, Canadian Steel Tool Co.; director, Canadian Lake and Ocean Navigation Co.; vice-president, Imperial Guarantee and Accident Co.; vice-president, Title and Trust Co., and director, Sterling Bank.

He was also a member of the Board of Education in 1890-1891; has been a member Board of Trade since 1889; was for some years a member of the Council; and for the past ten years has represented the Board of Trade at the Canadian National Exhibition, of which he is vice-president.

NOEL GEORGE LAMBERT MARSHALL.

He is president of the Open Air Horse Parade Assn.; honorary president, Toronto Boys' Dominion; vice-president, National Chorus; vice-president, Provincial Council of Canadian Boy Scouts; member, Ontario Parole Commission; treasurer Laymen's Missionary Movement of the Church of England; governor, Western Hospital; vice-president, Hospital for Incurables; member of Board, Children's Aid Society, Orphan Boys' Home, Working Boys' Home, British Welcome League, Imperial Daughters of the Empire, Women's Welcome Hoatel, Imperial Home Reunion, Georgina House, Bishop Strachan School.

Mr. Marshall married Harriette Isabel Hogg, daughter of John Hogg, M.P., York Mills, in 1879, there being two sons of the union.

His clubs are the National (president, three years); Granite, Albany, R.C.Y.C., Ontario Jockey, Toronto Hunt, Caledon Mountain Trout(Chairman, House Committee); Burlington Country, Buffalo and Buffalo Country, Canadian Society of New York, Royal Colonial Institute (London), while the societies of which he is a member consist of the A. F. and A. M. (Zetland Lodge), S.O.S., and St. George's, the latter of which he is a life member.

In politics, Mr. Marshall is a Conservative and in religion an Anglican, he having been a warden of St. Matthew's Church, Toronto, for over 20 years.

His town residence is 623 Sherbourne Street,Toronto, and his summer residence, Dunbarton Farm.—Photo, courtesy, The International Press.

The General Market Conditions and Tendencies

This section sets forth the views and observations of men qualified to judge the outlook and with whom we are in close touch through provincial correspondents.

Montreal, Que., July 13, 1914.—Dullness is still the outstanding feature in machinery circles and there does not appear at present to be much prospect of an improvement for some weeks to come. The report which appeared in the daily press last week to the effect that the Canadian Northern Railway had placed an order with the Canadian Car & Foundry Co., for about $750,000 worth of cars, created some excitement, but there was keen disappointment when it was learned that this order was for passenger cars only. While this will provide work for the car company for some time to come, it does not have the same effect on the metal situation, as an order for freight cars would have.

There is still a considerable amount of building being carried on locally, but supply men state that the contractors must be using their old equipment as the orders for new stuff are few and far between. There have been some small orders for mixers, and there is also some business being done in road-making machinery, but generally quietness pervades.

Some interest was aroused by the announcement that the contract for building the new Union Station in Toronto had been awarded to a Montreal firm, the Lyall Construction Co. The new structure will cost in the neighborhood of $4,000,000. It is stated that the harbor commissioners of Montreal will erect another two-million bushel elevator on the harbor front, as an addition to the present No. 1 elevator near the White Star wharf.

Metals.

There is little, if any, improvement, in the situation as regards metals. Sales are still of a hand-to-mouth character and no large orders have been placed for some weeks. One authority states that the big car companies who usually take enormous quantities of pig iron, had this year not taken 10 per cent. of last year's amount. Most of the big industrial plants are working with greatly reduced forces and it is likely that this state of affairs will continue for some time yet. An improvement is looked for in the early fall, and it is not likely that any change will be experienced before that time. Metal markets are rather quiet, though the opinion now seems to be that prices will not go any lower. Sterling quotations to-day are: Tin, spot, £146.5; futures, £147.15; copper, spot £61.10; futures, £62; lead, £19.7.6; spelter, £21.10.

Toronto, Ont., July 14, 1914.—No change is noticeable in business conditions this week, but the feeling appears to be gaining ground that the outlook is improving, and that a return to better conditions may be expected in the fall. Outside influences, which are affecting the market unfavorably, have been to some extent discounted, while the crop reports continue favorable, although rain is needed in some districts. This depression, largely the result of overconfidence in the possibilities of the country, and too rapid development, is gradually passing, and more stable business conditions will follow as the result.

The wealth of the country, in its natural resources, is becoming more apparent each year. Trade depression does not affect this vital feature, but only checks development for a more or less brief period. The temporary decrease in the amount of capital coming into the country from abroad for investment, likewise only retarded development, and does not affect the possibilities of further expansion, providing confidence in the future of the country is maintained.

A great deal of satisfaction has been expressed locally, now that the contract has been let for the construction of the new Union Station. The contract, involving the expenditure of over four million dollars, has been awarded to the Peter Lyall & Sons Construction Co., of Montreal. It is expected that the work will be completed in about three years. Not only will it result in a station worthy of the city, but it will also help meantime to relieve the labor situation, which, it is anticipated, will be a difficult problem to solve this coming winter, on account of the general depression.

Steel Market.

There has been no material change in the steel market during the week, and no marked activity is expected this month. Prices have not changed, and it is probable that an improvement may be deferred for some time. The building trade as it affects structural steel is quiet, and building permits continue to show a decrease.

The steel trade in the United States is showing indications of an improvement, while it is reported that manufacturers are confident that the remainder of the year will show a much larger volume of business than the first half. It was anticipated that the majority of the mills would shut down for two weeks, as is usual in July. The fact that operations have been resumed after only one week's idleness is significant.

Pig Iron.

The situation in the pig iron market shows no noticeable improvement, and prices have not changed. Consumers are continuing to buy only such amounts of iron as are necessary to cover their immediate requirements. Manufacturers are not accumulating stocks.

Machine Tools.

The machine tool market is quiet. The occasional sales being booked by dealers are not sufficient in number or in size to alter the state of dullness, which has been prevalent so long.

Metal Markets.

The metal markets are still quiet, although a little more business is passing than was the case last week. Buying is still of the hand-to-mouth order, and consumers are keeping stocks as low as possible. Prices generally rule the same, with the exception of tin, which is weaker.

St. John, N.B., July 13. — Five hundred feet of wharfage has already been completed by the Maritime Dredging & Construction Co. at West St. John, and every effort is being made to have the new berths ready for the early winter with the re-opening of the busy steamboat season. One million five hundred feet of Georgia pine reached the city a few days ago, and two million more feet are on order for delivery early next month. The Construction Co. now has three of the largest reclamation plants available at work with a big crew of men. Two large concrete distribution towers for the better handling of the concrete are to be erected this week. These towers will be eighty-five feet high.

A Board of Trade committee consisting of the chairman, P. W. Thomson, A. H. Wetmore, and J. Hunter White, with the secretary, R. E. Armstrong, last week visited the works under construction at Courtenay Bay, and were pleased with the progress being made, on the breakwater, dredging, and other operations. Three hundred and fifty men are employed. The committee announced that wharf building at Courtenay Bay will be started on or about May 1, 1915.

For some time there has been under consideration a project of closing the gap between Partridge Island and Negro Town Point at the entrance to St. John harbor, and now the engineers of the Department of Public Works, have recommended that the work be done. Tenders are soon to be called by the Department for the extension of the breakwater, following the call for tenders for the construction of steel sheds on the wharves building by the Maritime Co.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News.

Engineering

Prince Albert, Sask.—The La Colle Falls power development may be taken over by Kittel & Co., London, England.

Tilbury, Ont.—The Town Council will probably purchase water-works equipment shortly. W. H. Hutton, town clerk.

West Lorne, Ont.—The West Lorne Motors Co. contemplates the purchase of equipment for the manufacture of autos and motor fire engines. H. A. Carmichael, manager.

Galt, Ont.—A by-law will be voted on by the ratepayers on July 30 to authorize an issue of debentures for the purpose of providing a loan of $12,000 to the Galt Machine Screw Co.

St. Thomas, Ont.—The city council at a meeting held on July 8, adopted a resolution authorizing the expenditure of $20,000 for repairs and improvements to the present gas works plant.

Sherbrooke, Que.—Sherbrooke Construction Co. has been awarded the contract for the construction of a machine shop for the Sherbrooke Machinery Co. H. G. James, Whiting Block, is the architect.

Kerrobert, Sask.—A contract has been let to K. Pederson for the construction of the Kerrobert Steel & Ironworks, Ltd. The main building will be 60 x 200 feet and two stories high. The company is capitalized at $100,000, and the principal product will be structural steel.

St Thomas, Ont.—Work will be commenced at once on the erection of the big purifying plants in the fields of the Southern Ontario Gas Company at Glenwood, according to G. H. Houston, a member of the engineering staff of Henry L. Doherty, president of the Doherty syndicate, which owns the Southern Ontario and kindred companies in Ontario.

Calgary, Alta.—The Buckeye Engine & Foundry Co., of Joliet, Ill., have purchased from the Alberta Financial Brokers several blocks of land in their new industrial site east of the city. This concern are large manufacturers of gas and steam engines, cement mixers, large steel tanks, building and construction steel, derricks, well and oil drilling machinery, and other such lines.

Sault Ste. Marie, Ont.—It is announced that a factory for the manufacture of their products will be erected here by the Seelye Combination Axe & Tool Co., Ltd. Plans for the building are in course of preparation and it is probable that actual construction will be under way before many weeks have passed. The proposed building will be 60 x 70 feet and two storeys high.

Toronto, Ont.—Preparatory work has been started in connection with the construction of the new $1,700,000 auxiliary plant to the filtration plant at the Island. Under the supervision of Mr. Butler, William Cowlin & Sons have started the erection of blacksmith shops, carpenter shops, storage rooms, offices, stables and other necessary buildings in the vicinity of and just north of the present filtration plant.

VICTORIAN RAILWAY, AUSTRALIA, WORKSHOP TENDERS.

In addition to the tender forms and specifications already forwarded, Commissioner D. H. Ross has added some further details as to equipment required for the Victorian Government Railway Department. Particulars of these requirements are indicated in the following brief summary, together with the dates on which the tenders close at Melbourne:

25755—October 7, 1914—4 motor driven air compressors.

26110—October 7, 1914—80 sets assorted motor equipment

Specifications and tender forms are now available, for the specification of Canadian machinery manufacturers, at the Department of Trade and Commerce, Ottawa, from whom particulars relative to the departure of mails for Australia can also be obtained.

Electrical

London, Ont.—The Hydro-Electric Commission is contemplating the purchase of electrical equipment, including new transformers and generators for new power station.

Belleville, Ont.—The council has approved of a by-law relating to a contract with the Trenton Electric and Water Co. for lighting the streets. Over 500 tungsten lamps will be required.

Toronto, Ont. — At the Etobicoke Township Council meeting held on July 6, a petition was presented by E. S. Scoll and signed by a large number of residents living in the Long Branch district, asking that a Hydro-Electric house-lighting system be installed in the district west of New Toronto and east of Browne's line.

Municipal

Chatham, Ont.—The Chatham Gas Co. has refused the offer of $410,000 made by the city for their plant.

Stettler, Alta.—Extensions are contemplated to the waterworks system. J. Jamieson engineer.

Listowel, Ont.—The town council contemplates installing a new water-works pump, additional mains and equipment.

Montreal, Que.—The Board of Control will call tenders shortly for a 24-million gallon pump. L. W. Seneeal, secretary.

Windsor, Ont.—The city has purchased two motor trucks for the fire department from the Menard Commercial Car Co. of Windsor.

Guelph, Ont.—After October 1 the office of publicity commissioner will disappear. Robert McDonald, the commissioner, was appointed four years ago.

London, Ont.—Local improvements to the value of $267,242 are under construction or are soon to be undertaken by this city. An extensive storm sewer system costing $250,000 is also being installed.

Stratford, Ont.—The water commission will likely ask the city council to submit a by-law to the ratepayers in January next for "standpipe accommodation." It has been suggested that a 500,000 gallons capacity standpipe be erected. Mr. C. McIlhargy is chairman of the commission.

St. John, N.B.—The council are in the market for a quantity of galvanized iron pipe, sizes 2 in. to 8 in. diameter, inclusive. R. W. Wigmore water commissioner.

Sherbrooke, Que.—A by-law authorizing the City Council to borrow $200,000 for permanent improvements to the streets was passed by the council last Thursday. The by-law will be submitted to the ratepayers on July 27.

Stratford, Ont.—At its third meeting to consider the matter, the City Council on July 6, gave the third reading to the much-read incinerator by-law. This means that the incinerator plant will be situated on St. Patrick street, and that steps will be taken to expropriate the Burrit property for that purpose.

Newmarket, Ont.—A small vote was polled on July 6, on the two money by-laws submitted by the council, and out of a voters' list of about 1,000, only 370 voted. The by-law to raise $15,000 to extend the water system was passed with the small majority of four, while the other by-law of $5,000 to construct concrete sidewalks was defeated by 15 votes.

Calgary, Alta—The city commissioners agreed a few days ago to submit the new Louis bridge by-law, which substitutes a concrete structure for the iron one recently authorized by the citizens, and the Fourth street subway by-law at an early date. They also agreed that the by-law for the purchase of Hillhurst Park, which was defeated in April should be re-submitted to the ratepayers with these two. Nothing was decided as to parks or publicity.

Stratford, Ont.—The council has entered into an agreement with a Brantford promoter to give this city a street motor bus service. The service will be begun in about fifteen days by a joint stock company which has been awaiting the decision of the City Council before becoming incorporated. The company has been granted the exclusive right to run motor busses on the streets of Stratford on and after July 25, 1914. It agrees to operate three motor busses of between thirty and forty horse-power with a passenger capacity of 14 each.

General Industrial

Windsor, Ont.—J. T. Wing & Co. will build a new factory to cost $36,000. T. C. Pennington architect, Windsor.

Montreal, Que.—Jas. M. Aird, St. Urbain Street, will make extensions to his bakery. Gordon & Aird architects, Montreal.

Port Stanley, Ont.—The Producers Fish Co. has awarded the general contract for the construction of a $7,000 fertilizer plant to L. H. McIntyre. General manager, F. R. Robbins.

Port Dover, Ont.—Fire destroyed the plant of the Port Dover Brick & Tile Co. here last Saturday. The loss is $20,000, with no insurance, and twenty men are thrown out of employment. Mr. C. W. Barwell is the president.

Stratford, Ont.—The names of the promoters of the Stratford motor bus service are Fred Westbrooke, Brantford; W. Schultz, of Schultz Bros. Co., Ltd., Brantford; Dr. Hart, Brantford, and Norman R. Thompson, commercial traveler, Brantford.

Windsor, Ont.—Horlick's Malted Milk Co., of Racine, Wis., has purchased a tract of twenty acres on Tecumseh road, this city, and will erect a large plant for the Canadian trade. It is stated upwards of five hundred hands will be employed. The price paid for the property was about $1,500 an acre.

Montreal, Que.—Hanan & Sons, the large boot and shoe manufacturing firm of New York, are to build a factory here before the end of the year, according to the statement of C. de Forest Smith, agent, on his return from a trip through the Dominion to investigate trade conditions.

Winnipeg, Man. — "If the raw material suitable for the manufacture of fire-clay goods can be found in sufficient quantities near Winnipeg, there is every possibility that my firm will establish a manufacturing branch here in the near future," said W. R. Pickup, of W. R. Pickup & Co., Norwich, England, earthenware manufacturers.

Hamilton, Ont. — It is reported here that the Eagle Knitting Mills and the Eagle Spinning Mills Co., both of which are owned and operated by Col. J. R. Moodie and his sons, will be part of a big merger of similar interests, including the Penman mills at Paris. It is said the Moodie mills here will be accepted at a valuation of $1,500,000, and that they will continue under the present direction for a considerable term.

Estevan, Sask.—At a regular meeting of the Board of Trade recently, the deal between Mr. Bernstein, of Winnipeg, and the Board of Trade was practically closed. The board will transfer to him the half section south-west of town known as the Steele homestead, which will be the site for a large pottery plant. Mr. Bernstein has agreed to erect a $100,000 plant there, and is at the present time engaged in securing the necessary capital for his company.

Contracts Awarded

Port Hope, Ont.—The contract for harbor improvements has been awarded by the Dominion Government to Tompkins & Cunningham, of Ottawa.

New Toronto, Ont.—The village council has awarded a contract to M. J. Curley, Toronto, for laying an 18-in. intake pipe in connection with the new waterworks system. The contract amounts to $7,050.

Toronto, Ont—Peter Lyall & Sons Construction Co., of Montreal, has been awarded the contract for the building of the new Union Station. The amount involved is between $4,000,000 and $5,000,000, and the work will take nearly three years to complete.

Edmonton, Alta.—The contract has been awarded to the American La France Engineering Co., Elmira, N.Y., for the supply of one 4-cylinder combination chemical and hose motor car ($7,370); two 6-cylinder combination pumping and hose motor cars ($23,200), and one 6-cylinder motor service hook and ladder truck ($8,270).

Ottawa, Ont.—The contract for the final link in the Trent Canal system was let on July 9 to the Randolph-Macdonald Co., of Toronto, at $901,141. This is section three of the Severn River division, and the letting of the contract means that in little more than a year the Trent Canal will be completed from Lake Ontario to the Georgian Bay.

Estevan, Sask.—The following contracts have been awarded for supplies required and for the construction of water mains, etc:—Contract (a) for the laying of approximately 10,500 feet of water mains and 16,000 feet of sewer pipe, to W. S. Coffin, of Estevan, at a total cost of $39,126; (d) for the furnishing of cast iron water pipe and specials, to the United States Cast Iron and Foundry Co., of Chicago, at $39.30 for 6 and 10-inch pipe per ton, and $72.50 per ton for specials, totaling $8,870; (e) for furnishing of hydrants and gate valves, to Jenkins Bros., of Montreal—hydrants $41.05 each, 10-inch valves $29.30 each, 6-inch valves $10.95 each, and valve boxes complete $7.30 each.

Calgary, Alta.—Contracts have been awarded as follows:—Cast iron pipe, to the Canada Iron Corporation, Fort William, Ont.; 6-inch steel pipe, to the Western Fonndry and Metal Co., for Page Hersey pipe at 57 cents per foot, and to the General Supplies Co., Ltd., for Stewart and Lloyd pipe at 55 cents per foot, each firm to supply 22,100 feet; 8-inch steel pipe, to the same two firms for the same makes, each to supply 2,275 feet at 76 and 77 cents respectively; 10-

inch steel pipe, 8,300 feet, to the Western Foundry and Metal Co. for Page Hersey pipe at $1 per foot; 12-inch steel pipe, 3,500 feet, to Gorman, Clancy & Grindley, for National pipe with Matheson joints and National coating at $1.22 per foot; 16-inch steel pipe, 3,500 feet, to Smiley & Co., for National pipe with Matheson joints and National coating at $2.14 per foot; and 20-inch steel pipe, 1,820 feet, to the General Supplies Co. for Stewart and Lloyd pipe, at $2.80 per foot.

Winnipeg, Man.—The following contracts have been awarded for manufacture, delivery and installation of approximately 5,500 feet of 3-core, paper insulated, 1,300 volt cable, to the Canadian British Insulated Co., Montreal, amounting to $7,000; for manufacture and delivery of 40,000 pounds of waterproof insulated copper wire, to the Standard Underground Cable Co., Hamilton, at $6,700; for electrically operated switching apparatus and accessories, to the Canadian Westinghouse Co., Hamilton, at $5,600; for supply of arc lighting equipment and automatic series cut-outs and accessories, to the Canadian General Electric Co., at $3,300 for each equipment for one year's supply of equipments; and for induction feed regulators, single phase, to the Canadian Westinghouse Co., at $2,071, and three phase, to the Canadian General Electric Co., at $4,600.

Tenders

Toronto, Ont.—Tenders for lead-covered cable will be received until Thursday, July 30th, 1914. Address the chairman, Toronto Electric Commissioners, 226 Yonge Street.

Toronto, Ont.—The Toronto Terminals Railway Co., is calling tenders for a temporary trestle. Particulars may be obtained from the office of the company, 114 Dowling avenue. Tenders to be in by August 15, 1914. J. R. W. Ambrose, chief engineer.

Hanover, Ont.—Tenders for waterworks extensions addressed to the town clerk will be received up to Tuesday, July 21st, 1914, for (a) supply and erection of 100,000 gallon steel water tower; (b) cast iron piping and valves; (c) laying piping, valves and fittings. Copies of specifications of requirements can be obtained from the town clerk, John Mills.

Toronto, Ont.—Tenders for motor-driven fire apparatus, fire hose and rubber covered tarpaulins will be received up to Tuesday, August 11, 1914. Specifications and forms of tender, together with the conditions governing tenders, may be obtained upon application at the office of the Fire Department, No. 152 Adelaide street west, Toronto.

Montreal, Que.—Tenders for the supply and delivery of one 7-passenger touring car and one auto ambulance, addressed to the Board of Commissioners will be received until Friday, July 17, 1914. The specifications, forms of tenders and all information required, may be obtained at the office of the superintendent of purchases and sales, City Hall. L. N. Senecal, secretary.

Toronto, Ont.—The Board of Education will receive tenders up to Wednesday, July 22nd, 1914, for equipment for the new Central Technical School, consisting of plumbing, wiring, gas-fitting, etc., also refrigeration and filtration plant. Plans and specifications may be seen at the offices of the engineers, the Canadian Domestic Engineering Co., 47-51 King Street West. W. C. Wilkinson secretary-treasurer.

INQUIRIES FOR WIRE FENCING.

The Department of Trade and Commerce, Ottawa, intimate that during the past week inquiries have been received for wire fencing suitable for agricultural purposes. It is understood that the manufactures of one Canadian firm are already commanding a good sale in the West of England, and there exists evidence that sales can be considerably augmented as the wire fencing becomes better known.

Ottawa, Ont.—Tenders for the construction of a public building, Durham, Ontario, will be received until Monday, July 20, 1914. Plans, specification and forms of contract can be seen and forms of tender obtained at the offices of Forster & Clark, architects, Owen Sound, Ont.; Thos. Hastings, Clerk of Works, Postal Station "F," Yonge St., Toronto, Ont.; the Post Master, Durham, Ont., and R. C. Desrochers, secretary Department of Public Works, Ottawa.

Ottawa, Ont. — Tenders will be received until Tuesday, August 11th, 1914, for the construction of section 2 of the Jetty at Steveston, at Mouth of the Fraser River, B.C. Plans and form of contract can be seen and specification and forms of tender obtained at this department and at the offices of the district engineers, at New Westminister, B.C.; Victoria, B.C., and on application to the postmaster at Steveston, B.C. Blue prints can be obtained at the Department of Public Works by depositing an accepted bank cheque for the sum of $50.00, made payable to the order of the Honorable the Minister of Public Works, which will be returned if the intending bidder submit a regular bid. R. C. Desrochers, secretary, Department of Public Works, Ottawa.

Ottawa, Ont. — Tenders will be received up to Monday, July 27, 1914, for the laying and jointing of about 13,000 lineal feet of 20-inches interior diameter lap-welded steel pipe for a new water main for the Town of Banff, Alta. Specifications may be had from the Commissioner of Dominion Parks, Ottawa, Ontario, the chief superintendent of Dominion Parks, Edmonton, Alberta; the superintendent Rocky Mountain Parks, Banff, Alberta. Lyndwode Pereira, secretary Department of the Interior, Ottawa, Ont.

Ottawa, Ont.—Tenders will be received until Monday, August 10, 1914, for the construction of steel gates, towers and operating machinery for the regulating dam, Big Chaudiere Falls, French River, Ont. Plans and form of contract can be seen and specification and forms of tender obtained at this Department and at the offices of the District Engineers, Confederation Life Building, Toronto, and Shaughnessy Building, Montreal. Blue prints can be obtained at the Department of Public Works by depositing an accepted bank cheque for the sum of $20, made payable to the order of the Honorable the Minister of Public Works, which will be returned if the intending bidder submit a regular bid. R. C. Desrochers secretary, Department of Public Works, Ottawa.

Ottawa, Ont.—Tenders will be received until Monday, August 10, 1914, for the construction of repairs to eastern pier at Newcastle, Durham County, Ont. Plans and forms of contract can be seen and specification and forms of tender obtained at this Department and at the office of the District Engineer, Confederation Life Building, Toronto, Ont., and on application to the Postmasters at Kingston, Ont., and Newcastle, Ont. Blue prints can be obtained at the Department of Public Works by depositing an accepted bank cheque for the sum of $20, made payable to the order of the Honorable the Minister of Public Works, which will be returned if the intending bidder submit a regular bid. R. C. Desrochers, secretary, Department of Public Works, Ottawa.

The Pas, Man.—Tenders will be received up to August 11, 1914, for the supply and delivery of the following machinery and materials:—(a) For the supply and delivery of two sewage lift pumps; (b) for the supply and delivery of house meters; (c) for the construc-

tion of sewage lift chamber and oil tank chamber. Plans and specifications may be seen at the offices of the consulting engineers, Saskatoon, Sask., or the resident engineer, The Pas, Man. A complete set of plans and specifications will be forwarded on deposit of $25 and a set covering all contracts on a deposit of $50, which deposit will be returned on receipt of a bona-fide tender and return of specifications. Specifications on house meters to be obtained from the Saskatoon office only without charge. Murphy & Underwood consulting engineers, Saskatoon. H. H. Elliott secretary-treasurer, The Pas, Man.

New Incorporations

The Ford City Metal Products Co., has ben incorporated at Toronto with a capital of $100,000, to deal in metal products at Ford City, Ont. Incorporators: J. H. French, W. F. Tant, and H. P. Cope, of Detroit, Mich.

The Coomac Oil Felds, Ltd., has been incorporated at Toronto with a capital of $3,000,000, to carry on business as mine owners. Incorporators: G. H. Sedgwick, J. Aitchison, and H. Morwick, all of Toronto, Ont.

The Canadian Storage Battery Co., has been incorporated at Toronto with a capital of $40,000 to carry on a storage battery business at Toronto. Incorporators:—R. A. Reid, H. R. Moses, and D. J. Coffey, all of Toronto, Ont.

The White Reserve Mining Co., Ltd., has been incorporated at Toronto with a capital of $200,000 to carry on business as mine owners. Incorporators: J. T. White, H. Ferguson, and G. R. Sproat, all of Toronto, Ont.

The Imperial Waste & Metal Co. has been incorporated at Ottawa with a capital of $50,000 to carry on business as general merchants at Montreal. Incorporators: A. R. Hall, L. Fitch, and P. A. Badeaux, all of Montreal, Que.

The National Contracting Co., Ltd, has been incorporated at Toronto with a capital of $40,000, to carry on the business of general contractors at Toronto. Incorporators: W. J. Haynes, F. Reeve, and W. M. Hall, all of Toronto.

The Port Colborne Dock & Coal Co., Ltd., has been incorporated at Toronto with a capital of $50,000, to carry on business as coal dealers, ship owners, etc. Incorporators: J. A. Kent, L. G. Jarvis, and F. Walkingshaw, all of Toronto, Ont.

The Krotum Co., Ltd., has been incorporated at Toronto with a capital of $25,000 to deal in electro-plating and polishers' supplies at Toronto. Incorporators: A. Kortum, of Toronto; H. D. Metcalfe, and C. M. Metcalfe, of London, Ont.

The Du Pont Safety Powder Co., of Canada, has been incorporated at Ottawa with a capital of $2,000,000 to manufacture explosives and ammunition at Montreal. Incorporators: D. P. Gilmor, F. G. Bush, and G. R. Drennan, of Montreal, Que.

Building Notes

Montreal, Que.—Reid, McGregor & Reid, Drummond Building, have secured the general contract for the erection on Beaumont Street of a $32,000 four-storey factory of brick construction, for Martin-Senour Paint Co. W. B. McLean, 204 St. James Street, is the architect.

Toronto, Ont.—The Samuel Trees Saddlery Hardware Co., 42 East Wellington street, have bought the property at 59 Frederick street at an estimated cost of about $22,750, from John Hamilton. The present old building will be demolished and a modern warehouse will be erected. The lot has a frontage of 64 feet and a depth of 130 feet.

Toronto, Ont.—Bohan Bros., of 43 Adelaide street west, wholesale woolen manufacturers, have purchased three blocks of property on the south side of Adelaide street, between York and Simcoe streets, on which they will erect a first-class warehouse. The total frontage of the three parcels is 145 feet, and the depth of each 91 feet. The price is understood to be a little over $100,000.

Toronto, Ont.—The new police administration building will cost over a million dollars, probably a million and a half. Early next week Controllers O'Neill and McCarthy will submit a report to the Board of Control recommending the size, method of arrangement of the interior and general construction. The building will be ten stories high and of concrete and steel construction, absolutely fireproof throughout.

Toronto, Ont.—The contract for the new 11-storey Excelsior Life Building to be erected on the north-west corner of Adelaide and Toronto streets has been let to the Peter Lyall Construction Co., and the work of demolishing the old Cornell block has begun. The Excelsior Life's new home will cost $300,000 or more, and will be ready in about twelve months. The first two storeys will be of granite and the remaining storeys white glazed terra cotta.—E. J. Lennox, architect.

Railways-Bridges

Moose Jaw, Sask.—Mayor Pascoe has received from the G.T.P. a cheque for $30,000, being the amount asked by the city for the land required in the exhibition grounds for a railway station. Thus the much-vexed question as to where the G.T.P. passenger station and freight terminals would be located in Moose Jaw is now finally settled.

Brantford, Ont.—By August 1 the Brantford Street Railway and the Grand Valley Railway will belong to the city. The contract is signed between the city and the Grand Valley bondholders, and all that is keeping the actual transfer from going through is the fact that the work of checking up the title deeds to the property and the right-of-way is not yet completed.

Toronto, Ont.—The East York Township Ratepayers' Association held a meeting on July 4 at the Don Schoolhouse to consider the plans, drawn by the township engineer, Frank Barber, for a high level bridge across the West Don, at Eglinton avenue and Leslie street. The bridge is to be 42 feet wide, with 6 ft. extension sidewalk on each side. It will be 70 feet above the water of the river, and will provide for two tracks sufficient to carry a trolley line. The cost will be about $150,000.

Victoria, B.C.—Mr. D'Arcy Tate, vice-president of the Pacific Great Eastern Railway, with headquarters at Victoria, has been advised that an order has just been placed for fifty flat cars, in preparation of starting track-laying south of Fort George late this summer. Additional equipment for the north shore portion of the line is expected to reach Vancouver next week. One gasoline motor car, of a larger and more powerful type than those already in service, and three passenger coaches were ordered a short time ago. The contractors expect that grading will have been sufficiently advanced on the sections south of Fort George to commence laying steel in September.

Refrigeration

Moose Jaw, Sask.—Moose Jaw Abattoir Co. has secured a site for the erection of a $60,000 abattoir, 200 x 70, to be completed by July 1, 1916.

Butedale, B.C.—John Wallace has just completed a new fish freezer and cold storage plant. The sharp freezer capacity is 100,000 pounds and storage capacity 1,000,000 pounds. Refrigerating is produced by means of a 100-ton Linde refrigerating machine operated by water power.

Interesting Data Relative to a Gear Testing Machine*

By Wilfrid Lewis**

The machine here described is believed to contain the elements needed for an exhaustive examination of the subject of gearing in all its phases, and the writer expresses the hope that it may appeal to someone with the means to build it and the time to experiment along the lines indicated by Professor Marx.

THE gear testing machine, shown in the accompanying drawing, is the result of the writer's efforts to realize in concrete form an ideal machine for the purpose of continuing the experiments reported to the society by Prof. Guido H. Marx at the annual meeting in 1912.

The possibility of testing heavier gears at higher speeds with comparatively little power occurred at once to Ralph E. Flanders and to the writer, as pointed out in their discussions of the paper, but the problem remained to design a suitable machine which might also be used to supplement the experiments made by the committee on standards for involute gears to determine the friction losses and the running qualities of various types of gearing. After making a number of preliminary sketches, the writer was about to put them in the hands of a draftsman, when he had the good fortune to meet Prof. E. P. Lesley, one of Professor Marx's associates, who accepted the task of preparing the working drawing. The machine as it now appears is due in large measure to his careful attention and skill in the perfection of every detail, and the writer is pleased to acknowledge many helpful suggestions which have broadened the scope of the undertaking and made the design a practical possibility.

The machine proposed is based essentially upon the principle of the machine used in testing by the committee on involute gears, which is to put the teeth under a working load without consuming an excessive amount of power. The design, however, has been modified to facilitate changes in the working load and in the test gears employed. At the suggestion of Professor Lesley, it has also become possible, not only to change the amount of the working load while running, but also to change its direction, thus producing the effect of reversing loads upon the teeth while running continuously in the same direction.

Machine Details.

The apparatus has a hollow shaft made in two parts, A_1 and A_2, united by a clamp, A_3, which is also made in two parts to facilitate assembling. At one end of this hollow shaft is a flange to receive the steel gear ring G, which serves as a permanent part of the apparatus, and is strong enough to resist the stresses due to testing. Besides the hollow shaft A, there are two solid shafts C and S, on which are mounted the gears or pinions to be tested. The latter passes through the hollow shaft A and has a flange, at one end of which is mounted the test gear T.

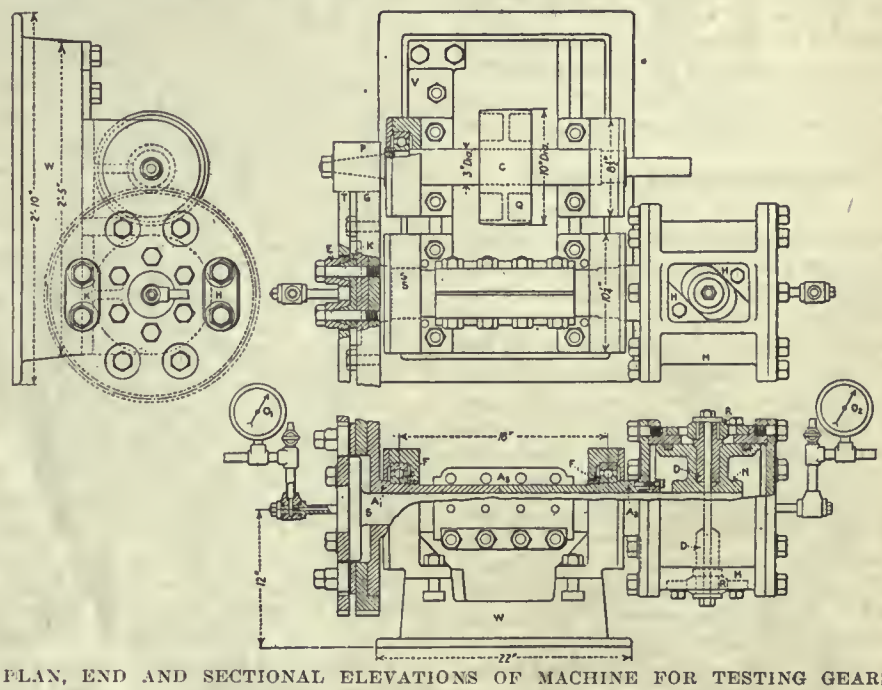
The shaft C, parallel with shafts A and S, carries the wide-faced pinion P, which is in mesh with both the permanent gear ring G and the test gear T.

Shafts A and S are connected at their opposite ends by a novel device through which any desired amount of load in either direction can be applied to the teeth, whether at rest or while running in either direction. To accomplish this purpose, the hollow shaft A is flanged to receive the pneumatic cylinder M, in which is the piston N, firmly secured to the shaft S. Pins D D are driven into the piston N through the openings in the cylinder M, and, upon the projecting ends of these pins, rollers R R are mounted upon roller bearings. A bolt passing through the pins, piston and shaft secures the whole in place. These rollers R R engage helical segments H H let into the walls of the cylinder M.

Air pressure can be applied to the piston N on either side to give a slight amount of end motion to the shaft S and so, through the action of the rollers upon the helical segments, a slight angular motion is produced between shafts A and S, resulting in a pressure between the teeth of the gears upon these shafts and the teeth of the pinion on shaft C. Pressure gauges O_1 O_2 connecting with each side of the piston area are calibrated to record the resulting pressure on the gear teeth, taking account of the piston areas, the pitch of the helical cams H, and the diameter of the gear wheels.

Since but little power is required to drive the apparatus, the pinion P is simply clamped to the shaft C by a nut on its tapered end. The shaft itself is made heavy for the sake of stiffness, and a pulley, O, between bearings, is attached for driving from a countershaft, or if preferred a motor drive may be used in connection with the extended end.

When the gear wheel T is to be tested, the intention is to use it in connection with a steel pinion; and when the pinion P is to be tetsed, the intention is to make it of cast iron and cut down the width of the teeth engaging with T by nicking down on either side to a smaller width of face. When a tooth breaks in the wheel T, or in the pinion P, it is im-



PLAN, END AND SECTIONAL ELEVATIONS OF MACHINE FOR TESTING GEARS.

*From a paper reecntly presented before the spring meeting of the American Society of Mechanical Engineers.

**President, the Tabor Mfg. Co., Philadelphia, Pa.

portant, in order to avoid the complete destruction of the apparatus by the jamming of the remaining teeth on their ends, to maintain the wheels G and T in proper relation to each other, and for this reason the stops K K, with their adjustable eccentrics E E, are employed. The block K is clamped to the wheel G through the intervening eccentric bushings E E. The intention is to keep one of the clamping bolts tight while the other is loosened and the eccentric adjusted to a predetermined amount of clearance on either side, after which both eccentrics are to be clamped.

—These stops do not come into action unless a tooth is broken or deformed. Then they cause both gears, G and T, to run together. By means of these stops it is also possible to study the effect of a predetermined irregularity in forming or spacing the teeth. For instance, an abnormally wide space or tooth can be simulated, when broken out or purposely cut away, by the position of the stops and the pounding effect in running will be evident as the result of a certain measured irregularity. The shafts A and C are mounted in ball bearings to reduce friction and as a matter of expediency the scale of the apparatus has been determined by the bearings F F on the shaft A. These are of the largest commercial size, and to make them available the shaft A was cut in two and united by the clamp A. The bearings for the hollow shaft are firmly bolted and doweled to a bed plate, W, while those for the pinion shaft are adjustable to the diameter of the pinion used, a distance piece, V, of proper width being used in every case to prevent movement under load.

Possibilities of the Apparatus.

It will be seen that the apparatus is capable of determining to a nice degree of accuracy a number of unsettled problems of great practical importance at a very small expenditure for wear and tear and power. Jigs will be made for drilling the gears G and T after cutting the teeth, so that the relative positions of the two wheels may be accurately fixed. Friction is practically eliminated in the ball and roller bearings, and what remains must become inappreciable under the well-known influence of vibration when running, except that due to air resistance and the friction in the teeth. With some accurate means for measuring the power consumed, both of these variables can be determined better than ever before.

The apparatus in skilful hands should, therefore, solve the mooted question of the effect of speed on strength, and questions of durability, wear and noise can be studied at a small outlay in power and materials. It is possible that some slight modifications may finally be embodied to facilitate construction.

SIGNED TRACINGS.

TRACINGS, and especially the uncolored cloth tracings which are used for reproduction by photographic process, can, says **The Engineer**, very readily be altered by erasure, as well as by addition, and in either case so as to leave no indication of the alteration which is apparent upon the photographic copies. Indeed, if ordinary care be taken in making the alterations they will more often than not be indistinguishable upon such copies from the original work, unless steps are taken to identify them by means of heavier lines or hatching, and, what is perhaps of greater importance, dating them.

It should be unnecessary to point out that no alteration should be made in a tracing which has been signed or initialled for approval or identification, unless the alteration is dated an so indicated as to be evident that it is not covered by the signature, or, in a case where there are many alterations, a note of revision subsequent to signature is placed where it is not likely to be overlooked.

A Drawing Office Tendency.

Many draughtsmen appear, however, to have a regard for neatness which causes them to overlook the grave impropriety of making such alterations without the necessary indications. They probably do it without thinking. The possibility of such unintentional alterations should, however, make anyone consider well before signing or initialling tracings which are likely to pass out of his immediate control. If, under such circumstances a tracing must be signed, it is desirable to have an immediate blue print taken off it for filing as a record and not for use. Such a print is inexpensive and practically unalterable, and affords—if duly endorsed and dated—good evidence of what has been signed. It will only serve, however, to detect, by a possibly laborious comparison, and not prevent alteration to the tracing, therefore, it is preferable, when drawings are submitted for approval, that they should be submitted in the form of prints in duplicate, one of which is to be retained. By this procedure the risk of signing a tracing is avoided.

To approve and sign a tracing, and let everyone concerned have prints showing the signature of approval is a course which has many convenient features, but there is always the risk of having undated and apparently trivial alterations and additions made to the signed tracing and the supply of prints continued. Where a number of copies or duplicates of the signed drawing is required, a possible procedure avoiding this risk is to sign the tracing in soft black pencil which prints perfectly by most processes, and after the necessary prints have been taken to remove the signature from the tracing. This leaves the tracing free for amendment and future use.

Transparent Cloth Prints.

A further risk arises from the facility with which a print on transparent cloth can now be obtained. These are sufficiently solid to be used as negatives for further reproduction, and as they can be altered by erasure, although not quite so easily as a hand-made tracing, they afford the readiest means of making a new drawing, involving a limited amount of alteration from an old one. They frequently reproduce faithfully the signatures, etc., upon the original, and the first step in making a new drawing in this manner by erasure or undated addition, should invariably be the erasure of any signatures, initials or indications of authorship which may be reproduced from the old tracing. A little consideration will show that this is the only correct thing to do, although the draughtsman may feel some reluctance to erase a respected name. If the previous history or authorship of the drawing demands acknowledgment, an equivalent note should be put in place of the erased signature or indication of authorship.

These may appear somewhat elementary matters, but a little inquiry will show that in the growth of mechanical processes of reproduction and an increasing disregard on the part of younger men for matters which they consider mere legal formalities, instances frequently occur in which they are overlooked. The consequences may not be serious, but it is better to avoid the risk of having an error introduced by a blundering draughtsman, under the impression possibly that he is merely correcting a clerical error, into a signed tracing from which prints containing the error indistinguishable from the original matter may be afterwards distributed.

Edmonds, B.C.—Upon the recommendation of Municipal Engineer McPherson, water pipe contracts to the amount of $23,882 were let to Robertson & Godson, Vancouver. The contract calls for 30,000 feet of 4-inch pipe for ordinary use, and 17,000 feet of duplicate delivery mains on Sperling Avenue. The engineer also recommended that Robertson & Godson's tender for various amounts of 4 and 6-inch be accepted, as well as supplies of 12, 14, 16 and 18-inch. The tender of the British Mannesman Tube Co. for the 10-inch pipe was accepted. A new 10-inch main will be run from North Burnaby to Edmonds once the shipment arrives.

PRODUCTION METHODS AND DEVICES

A Department for the Interchange and Distribution of Shop and Office Data and Ideas Evolved from Actual Practical Application and Experience

BORING MILL PRACTICE.—III.

By Albert A. Dowd.

THE present concludes the series of three articles on **Boring Mill Practice.** In our July 30 issue the first of another short series on **Turret Lathe and Vertical Mill Practice** will appear. The author of these articles is a recognized expert in production methods and devices, and his exposition of modern machine tool operation with a view to efficient and economical output will be found highly instructive by superintendents, foremen and operatives in both large and small machinery manufacturing plants.

Holding and Machining an Irregular Piece.

The work shown at A in Figure 7 is indicated in a plan view at B in Figure 1, and it is clearly apparent that the work must be located from the cored eccentric hole. The conical locating plug E is therefore brought into play to approximate the core. It is brought down into the work before the jaws are set up at all, after which they are set with sufficient power to hold the work firmly and an additional clamp C is used in one of the table tee-slots, being held down by the bolt D, a shim being placed under the tail of the clamp to exercise a slight drawing down tendency. The

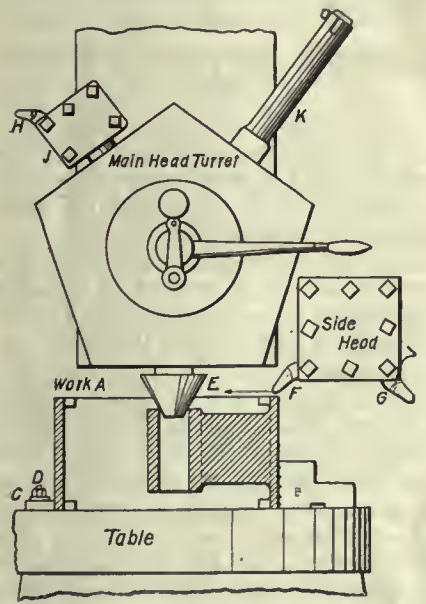


FIG. 7. USE OF CONICAL LOCATING PLUG FOR CORED HOLES.

tools used in this setting are those used in a previous one, no new tools being necessary, but the removal of several being found expedient in order to avoid interferences with the main head and side head.

The side head is first started in facing the rim working toward the center, the tool H in the holder J being used simultaneously in rough facing the hub. Tool G in the side head is next used for finish facing and the turret indexed to the boring bar position K. The table is speeded up and boring and reaming done with this bar by the aid of a set of slip cutters and floating reaming cutter of the proper sizes. The finishing operation for the other side of the piece was done on a vertical milling machine.

Machining a Thin Cast Iron Ring Without Distortion.

Figure 8 shows at A a thin cast iron shell which is to be machined to size without distortion. The method of holding a piece of work of this nature is perhaps more important than the actual machining operations as distortion in the rough casting will be apparent in the finished work. An excellent way of holding work of this kind when a number of pieces are to be machined, is by means of a set of so-called "hook-bolt jaws," i.e. a set of jaws provided with hook-bolts which pass entirely through and which can be drawn up against the surface so as to form an effective metal to metal clamp. Jaws of this kind are somewhat expensive unless the production warrants their use, in which case they will be found invaluable.

For single piece work, however, we must consider a method of handling which does not require a great expenditure. The method shown will give very good results if proper care is used in setting. The work is gripped from the inside in a set of regular jaws B, these being brought up against the casting very lightly so that no distortion will take place due to the pressure of the jaws. The piece is supported on three parallels of cold rolled steel as shown at C in the illustration. A set of standard screw dogs D are fastened in the table tee-slots at points in line with the jaws themselves, but outside instead of inside. After the work has been lightly gripped internally, the angular pointed screws E are set up tightly on the outer surface of the casting thus forming a metal to metal contact which does not distort the work and which serves two other purposes, viz.: holds the work firmly and also tends to prevent vibration which might otherwise cause considerable trouble. While this method is not quite as good as the hook-bolt jaws, it will be found of great service for any work of this character. A heavy boring bar G is used for both roughing and finishing the interior surface, slip cutters being used as in the

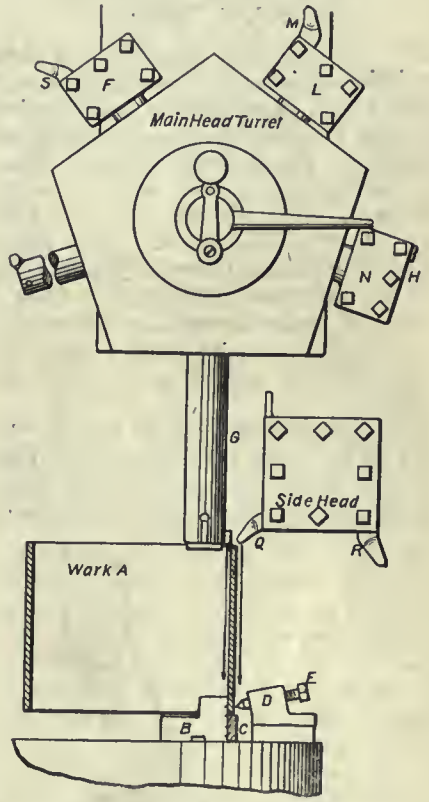

FIG. 8. METHOD OF HOLDING A THIN SHELL WITHOUT DISTORTION.

former instances. The main head turret is obviously set off-center a sufficient amount to obtain the correct sizes. The tool Q in the side head is used for rough facing the end of the shell and for rough turning the outside diameter.

An important point in the machining of this piece is that the turning and boring tools should be working directly opposite each other during the cutting as in this manner sizes will be held much closer and less vibration will take place. Special attention must also be paid to the feeds and speeds for, if feed is too heavy, chatter will probably develop on account of the torsion on the thin shell and the subsequent springing back into position. Speaking generally, a feed of about 1-32 in. per rev. with a speed of 40 feet per min. for roughing with a normal amount of stock to remove will be found about all that can with safety be used. The tool R in the side head is used for finish facing and turning. Feeds may be doubled for this operation without danger, and speeds slightly in-

creased. The final operation is that of cutting of the shell to the proper length with the parting tool in the side head. The casting was made long enough to allow for the waste caused by cutting off.

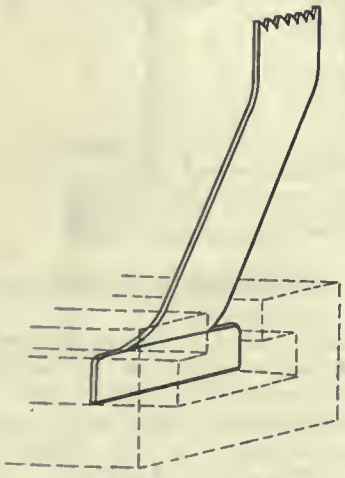
The principles involved in this method of handling thin work will be found to apply equally well to other work of a similar nature.

A TEE-SLOT CLEANER.

By J. E. Cooley.

FOR cleaning out chips from T-slots on lathe carriages, drill-press tables, and planer beds, a cleaner is used, having one end the same shape as the T-slot, as shown in the inclosed sketch. When pushed through the slot, chips are easily removed. This cleaner does not take out the oil or the very fine chips, therefore it is always necessary in order to get the slot thoroughly clean to force a piece of waste through it afterwards. The waste is usually pushed along the slot with the end of a file or screwdriver.

If a number of teeth be filed on the end of the cleaner, as shown here, they will be found very useful as a means when placed down against the waste to



A TEE SLOT CLEANER.

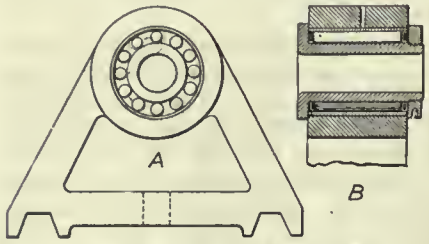
force it through the slot, and thus save the extra handling of something else in the operation. The teeth need not be sharp, as they serve just as well with the ends blunt.

A ROLLER BEARING STEADY REST.

By D. A. Hampson.

ONE of the lathes in the shop worked on cold rolled steel most of the time, and many of the parts turned up required the use of a steady rest. Even when carefully faced off and kept well lubricated, the jaws of the steady rest left a mark on the steel which was objectionable and, when a crease was roughed up on the work, the part had to be thrown away.

To overcome this trouble, a steady rest was made in a single piece—no hinged top section—in the form of an A with the legs resting on the vees and a hub at the vertex, as shown. This hub was bored out in line with the center of the lathe to take the sleeve B of a Hyatt



ROLLER BEARING STEADY REST.

roller bearing. It was proposed to make bushings of several sizes—5-16 in., 7-16 in., 9-16 in. and ¾ in, these being in frequent use, and have them all turned to a common outside diameter that would be a working fit in the cage of rollers. Through these bushings, the cold rolled steel rods would pass and, as the bushings turned with the work, the finished surface would be unbroken. A flange on one end of each bushing and a nut on the other kept out dirt and took care of end play.

The result was more than satisfactory. Not only was the finish preserved but the tools could be brought closer to the work and the latter, having a longer bearing in this steady rest than in the hinged style with jaws, was less springy Absence of the hinged top contributed to the general good, and the time saved in having no bolts to tighten and practically no oiling to do represented a considerable item. It has been said that a single piece design is the acme of mechanical construction, to which might be added, with anti-friction bearings, a statement borne out in the present and numerous other instances.

REPAIR TO LOCOMOTIVE FRAME.

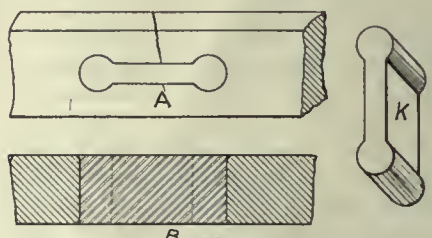
By Richard Bell.

A CRACK was developing in a locomotive frame, and when first observed extended half-way through. The following repair was made, which not only prevented the crack going further, but kept the engine on the road for a considerable time.

The direction taken by the break as well as the method of repairing is shown in the illustration. A hole was cut through the frame, as shown, two 1½-in. holes being first drilled 3¼ in. apart. This allowed for the drilling of three 1-inch holes between them. The metal left between the holes was now cut out, leaving it as shown at A. A key K was next made of sufficient length to go through the frame, which at this point was 5 in. thick. It was necessary in making this key to allow some draw so as to close up the crack and hold it tight.

The distance between the enlargements of the key was made ⅛ in. less than between the corresponding holes in the frame. The ends were made 1½ in. diameter and the connecting part 1 in. thick, these parts being made so as not to have a tight fit sideways. The edges were tapered off slightly so that the key would drive about ½ in. with a hand hammer. A piece of 4-inch shafting suspended from the roof was used as a ram to drive it home.

This form of key or fastening is usually referred to as a **Dutchman**, and is used for many kinds of repair work. Its most extensive use is probably in connection with the repair of circular saws, where by the use of a little draft and by riveting over the edges on both sides the crack and repair can be made almost invisible. A quick and effective way to fasten split wood parts is to bore a couple of holes and cut out be-



REPAIR TO LOCOMOTIVE FRAME.

tween in the same way; then to pour in melted babbit or other soft metal to form the **Dutchman**.—Editor.

HAMILTON INDUSTRIAL EXHIBITION.

An industrial exhibition was held during the past two weeks in Hamilton, Ont., at the Armories, under the auspices of the Y.M.C.A. It differed in many respects from that held last year.

There were only three exhibits this year of interest to readers of Canadian Machinery, these embracing the Pratt & Whitney, Dundas, Ont.; the John Morrow Screw & Nut Co., Ingersoll, Ont.; and the Canadian Hart Wheels, Hamilton, Ont. The Pratt & Whitney exhibit was in charge of G. A. Raynor. Here was to be seen an extensive line of cutters, reamers, twist drills, taps and dies, all of which contributed to a very effective display. Mr. Duncan looked after the interests of the John Morrow Screw Nut Co., their exhibit consisting of twist drills, machine screws, etc., in all sizes. F. S. Morison was in charge of the Canadian Hart Wheel exhibit, which embraced various shapes and sizes of grinding wheels and other emery and corundum products.

MOULDING MACHINE FOUNDRY PRACTICE.

By Arthur Smith.

FOR a great number of years it was the practice of a moulder to ram up his job, set the cores, carry iron to the mould in back-breaking bull ladles, shake out the casting, and in some shops cut up the sand before knowing that his day's work was finished. In the modern moulding machine foundry, however, an entirely different practice prevails, and the work is so divided or apportioned that several groups or "gangs" of men each receive the moulds for their share of the operation before the castings are finally delivered to the cleaning-room. This practice has been instituted owing to the tremendously greater output of castings demanded, and the fact that moulding machines can be operated much more economically when the shop is divided into sections.

The System in Practice.

The usual system is to divide the help in the foundry into ramming, finishing and coring gangs. The patterns are properly pinned to the jarring machine boards and brought to the several machines by the pattern handling crew. The ramming gang on the jarring machine proceed to ram the moulds, and, as soon as the patterns are drawn, the flasks are swung out and delivered to the second gang, whose duty is is to finish the jobs preparatory to sending them into the drying ovens. After the moulds are dried, they are delivered to the third floor, where the cores are set and jobs closed and made ready for the iron. Another crew, often night gang, now shakes out the castings and loads them on a car for delivery to the scratch room.

This practice, sometimes with slight variations, is followed in a great many foundries throughout the United States and Canada, and would not warrant mentioning were it not for the fact that the success enjoyed by some shops as compared to others is due to the manner in which the practice is carried out. The make-up of the different gangs requires careful study. The foundry manager must determine how much tonnage each machine should produce to turn out the work at a particular figure, invariably placed lower than he really hopes to reach. Then the jobs must be so arranged that each machine receives a sufficient number of the heavier pieces to bring its total output up to the tonnage required. This is a phase of the work that requires unceasing vigilance. The leader on the machine is usually ravenous for the heavier patterns, and if the selecting were left to his discretion it would be feast to-day and famine to-morrow.

Healthy Rivalry Among Operators.

When two or more machine gangs are working side by side, each aware of the tonnage expected of them to keep down the cost, the keenest kind of rivalry exists. The foreman must exercise rare judgment in giving out the jobs so that one floor may not receive too many "chunks" at the expense of his neighbor, and the facility with which crank disks, main bearing caps, etc., go through the shop forms an amusing contrast with the energy expended to complete an order of gear cases or other work of a similar nature. The leaders of the ramming gangs are naturally picked men, and the interest they manifest in getting out their tonnage seems infectious, and is transmitted to every member.

When the moulds come from the ovens they are taken in hand by several coring gangs under the same conditions as the ramming. Each particular crew has a certain tonnage to put up in order to turn out the work at the figure set by the foreman. They are trained men on coring, and the speed they attain from constant practice is marvellous. The jobs are laid out on the floors as they are taken from the cars, the cores are set, and the facility with which the moulds are prepared for the metal is remarkable. The same good-natured rivalry that exists on the ramming floors is present here, and the same natural desire to select the heaviest pieces is noticeable. It must not be inferred that day in and day out the tonnage sought for is accomplished, but the spirit of constant striving is there, and while on some days the nature of the work makes it impossible to get the tonnage desired, the average is kept up.

Typical Foundry Example.

In a typical jarring machine foundry the work is made in beveled flasks, cast in one piece without bars in copes. The flasks are standardized according to the product, and, of course, the object is to have the smallest number of sizes of flasks possible, so that each machine may have its own particular size of flasks, which it runs day after day, and there be no occasion for delay in rigging up or going into the yard for boxes.

It will be seen from the foregoing that the old method of each moulder personally superintending his own job from start to finish is obsolete so far as the modern foundry is concerned. The moulders of the old school have accepted the altered conditions, and may be seen wherever jarring machines operate, ramming, finishing or coring as the case may be.

EFFICIENCY IN THE ENGINEERING BUSINESS.—II.

By "Onlooker."

SCARCELY of less importance than efficiency in the drawing and designing departments of an engineering organization comes method in the other executive offices. The constitution of such executive will naturally vary between wide limits, according to the size of the concern. From the small repair shop, in which the manager often has vested in his own person the offices of draughtsman, estimator, sales manager, timekeeper and foreman, to the large engineering shop, which has its several departments to care for, these various matters, is a long step, and yet the same principles must underlie the work in every case in order to obtain the best results. In the larger concerns it should be the general manager's duty to exercise a supervision over the various executive departments as well as over the foremen and the shops. His business should be to organize and to study methods of increasing the efficiency of operation of his plant. Under him the various departmental heads should be made responsible for the detail work in connection with their various functions.

Cost-keeping and Estimating.

One of the most significant features of the modern engineering business is the growing attention which is being given to cost-keeping and estimating. Modern competition has rendered this essential. In the past, estimates were frequently prepared in a more or less rough-and-ready manner, without the previous compilation of reliable data of costs. To-day, however, the margin between profit and loss on any job has so narrowed, and quotations have been so finely cut down in order to secure work, that such a practice is no longer feasible. Accurate records must be kept that will show the cost of production, and to-day many

elaborate systems are in use to this end. Some of these have involved the expenditure of much time and money in their perfection, and are more or less costly to maintain, but the results more than justify the outlay of time, thought and money.

A number of the methods in use are, perhaps, needlessly elaborate. A system which is found to give results quite sufficiently accurate, which possesses the virtue of simplicity and which is cheap in operation, is as follows:—

The clerk or the timekeeper is detailed off every day to make a round of the shops and to record in a time book the hours which each man has put in on each separate job; to total each man's time on each job at the end of the week, and multiply it by the man's wages rate. The total wages paid to each employee at the end of the week is then apportioned and charged to the various jobs on which he has been employed. In the case of mechanists a fixed sum is added per hour for the use of the machine.

In Scotland it was common practice to reckon 10 cents per hour as a standard figure for all machines, and although some of the larger ones would cost much more than this figure, when all charges came to be summed up, others would cost less, so the amount named was found to give a very fair average. In Canada, however, a considerably greater figure would have to be employed, and, as this will vary somewhat in different localities, it is advisable for every shop to estimate its own machine charges.

In this estimation should be included depreciation of machinery and interest on capital invested, cost of power and a share of rental based on floor space occupied. In some cases the last charge is omitted, being taken account of in the form of a percentage added to actual production cost to cover all overhead expenses.

The exact percentage to add for overhead expenses is somewhat difficult to arrive at. Ground rental or interest on capital invested in ground, interest on capital invested in buildings and the depreciation of the buildings, office and executive expenses, insurance, advertising and selling costs, interest and depreciation on all equipment other than machine tools and a sum for replacing small tools and for miscellaneous expenses should all be considered in estimating overhead charges, and the relation of the total of these expenditures to the gross value of the output of the shop will govern the percentage to be added to the cost of raw material and labor in order to arrive at actual cost of production. General supplies, such as lubricants, red lead, waste and similar materials, are also often taken into account in the overhead charges for the sake of simplicity, and the same thing applies to lighting, water rates and works heating. Power, as already stated, is generally included in the running charges of the machinery.

Cost System Details.

The details of a cost system require careful working out, and can be perfected only after years of experience and trial. No one method can be applied to all cases, and what would be entirely satisfactory in one engineering shop might be totally unsuited to another. The system adopted must be modified to suit individual needs, and in the scope of this article it is impossible to do more than merely emphasize the necessity of an efficient system, and to broadly outline the direction in which such a system may be taught.

So much attention must be given to the producing end of the engineering industry that the buying and selling ends of the business are apt to take a second place and to be neglected to some extent. Yet selling effort is as important to the engineer as to the manufacturer of dry goods or patent medicines. The concern which seeks to widen and to increase its market can, by increasing its production, decrease the cost of production. Repetition work is the keynote of economic manufacture, and the bigger the operation of any engineering concern the greater in most cases is the opportunity of increasing the amount of repetition work. It is, therefore, obvious that well-directed selling effort is of prime importance. Not only will it obtain business of itself, but by cheapening production costs it will enable the firm to quote lower figures, and hence get greater trade. **The importance of advertising in suitable mediums cannot be exaggerated, and such advertisement should be followed up with a vigorous selling campaign. Publicity means bigger business, bigger turnover, cheaper production and larger profits.**

Following the Markets.

In purchasing judiciously, a considerable amount of money can frequently be saved. This department requires judgment and a careful following of market conditions. Just how much material to buy when the market is down is a problem that requires careful consideration. The market may fall still lower or the interest on the investment of heavy purchases for future use may more than outweigh the saving effected by purchasing on a falling market. One British firm known to the writer has made a long study of the business of buying, and its purchasing department has become expert in predicting the probable fluctuations of the market. It has on file the records, in graphical form, of the market changes on copper, pig iron, tin, zinc, aluminum and bar steel for a number of years, and these records prove of great value in predicting the probable fluctuations in the price of these materials from day to day.

A study of the markets is also of value in many instances in the estimating department, especially in shops handling heavy structural steel, where the cost is largely influenced by the price of the raw material. A rise in the price of steel of five or ten per cent. between the time of making an estimate and of ordering the material may, in the case of work of the nature indicated, make all the difference between profit and loss. We have to be content with small profits in these days if we want to get the jobs, and it does not do to trust to luck. Yet if markets are down at the time of submitting a tender for a job the contract for which may not be awarded for some time, it is advisable to reckon the raw material costs in the estimates at something above current prices in case of a rise, while if the market is strong it may sometimes mean the securing of the contract if the estimator makes some reduction in anticipation of the probable drop.

The importance of having full and reliable cost data in the estimating department has already been referred to. Without such data anything like accuracy is impossible. The data should, moreover, be in readily accessible and concise form. The slide rule in the department is essential, as it finds its greatest efficiency in the carrying out of quantities, and every man employed as an estimator should be a rapid and accurate worker on this useful instrument.

Question—A steel boiler flue 12 ft. long and 4 inches in diameter is worked under a pressure of 160 pounds per sq. in. How thick should the metal be?

Answer—The formula is $p = \frac{9{,}600{,}000t^2}{l\,d}$

or $t^2 = \frac{p \times l \times d}{9{,}600{,}000}$ or $t = \sqrt{\frac{p\,l\,d}{9{,}600{,}000}}$.

With a factor of safety of 6, the formula becomes $\sqrt{\frac{p\,l\,d}{1{,}600{,}000}}$, where p = pressure in pounds per sq. in. l = length of flue in inches. d = diameter in inches. 1,600,000—a constant which depends on the material, class of workmanship, etc. Substituting values, we have

$$t = \sqrt{\frac{160 \times 12 \times 12 \times 4}{1{,}600{,}000}} = \sqrt{.0575}$$

= .24, or about ¼ inch.

Series of Practical Questions and Answers for Mechanics

Every care is being taken to include only pertinent practical questions, and give same direct, reliable answers. Catch questions will be avoided. Attention is drawn to the alternating course in arithmetic, a concurrent study of which is recommended with that of the Question and Answer Series.

RELATING TO BEAMS.

BEAMS are of two principal kinds:—(1), Those supported at both ends and (2), those firmly fixed at one end with the other end unsupported. In determining strength of all beams the same formula, $\frac{M}{S} = \frac{I}{C}$ may be used in which:

M = Total bending moment in inch pounds which depends upon the type of beam and the manner of loading.

S=Greatest fibre stress caused by the loading of the beam, measured in pounds per sq. in.

I=Moment of inertia which depends upon the shape of the section and the direction about which it is taken. For instance, it is much greater about an axis at right angles to the face of a flat board than about an axis parallel to it. The formulae for all shapes likely to be met with can be found in any steel or engineer's hand book, while the values of I for all standard shapes and sizes are given already worked out.

C=The distance from the axis to the outside of the beam section in inches regardless of its shape. The axis is a line through the center of gravity or balance point of the section at right angles to the direction of the load.

• • •

Question.—A steel bar 2 ins. square is supported at two points three feet apart. If the strength of the material be 81,000 lbs. per sq. in., what load applied at its central point would be sufficient to break it?

Answer—Formula, $\frac{M}{S} = \frac{I}{C}$ or $M = \frac{I \times S}{C}$

For this type of beam centrally loaded $M = \frac{Pl}{4}$, where P = total load at center, and l = length in inches. We desire to find P, therefore formula becomes $\frac{Pl}{4} = \frac{I \times S}{C}$ or $P = \frac{I \times S \times 4}{C \times l}$

I for square section $= \frac{a^4}{12}$, therefore I for section 2 in. square would be $\frac{2^4}{12} = \frac{16}{12}$

S = 81,000; C = 1 in., and l = 36 in., then

$$P = \frac{16}{12} \times \frac{81{,}000 \times 4}{1 \times 36} = 12{,}000 \text{ lbs. or } 6 \text{ tons.}$$

• • •

Question.—A 4 in. × 10 in. plank of Georgia pine is supported at points 6 ft. apart. What concentrated load could it sustain at the center. (1)—When placed on edge. (2)—When placed on flat?

Answer.—Strength of Georgia pine is given at 8,000 lbs. per sq. in. for compression and 12,000 lbs, per sq. in. for tension. Use the lower value.

Formula, $M = \frac{I \times S}{C}$

For beam loaded in center, $M = \frac{Pl}{4}$ or $P = \frac{1 \times S \times 4}{C \times l}$

I for (1) $= \frac{bd^3}{12}$, where (b) = breadth and (d) = depth, or

$$I = \frac{4 \times 10^3}{12} = \frac{4 \times 10 \times 10 \times 10}{12} = 333.3$$

$$S = 8{,}000;\ c = \frac{10}{2} = 5;$$

$l = 6 \times 12 = 72$ in. then

$$P = \frac{333.3 \times 8{,}000 \times 4}{5 \times 72} = 29{,}629.6 \text{ lbs.}$$

I for (2) $= \frac{bd^3}{12} = \frac{10 \times 4^3}{12} = \frac{10 \times 4 \times 4 \times 4}{12} = 53.3$

$$P = \frac{53.3 \times 8{,}000 \times 4}{5 \times 72} = 4{,}740.7 \text{ lbs.}$$

• • •

Question.—A standard keeps cast iron test bar 1 in. × 1 in. × 12 in. long breaks under an average load of 3,000 pounds apllied at the center, what is the greatest stress in the material?

From formula of previous question, $\frac{I \times S \times 4}{c \times l} = P$ or $S = \frac{P \times C \times l}{I \times 4}$

In which S = stress required in pounds per sq. in.; C = distance from axis to outside edge of section; l = length in inches, and I = moment of inertia.

In above case, D = 3,000 lbs., C = 0.5 in., l = 12 in., I for square section $= \frac{a^4}{12} = \frac{1^4}{12} = .0833.$

$$S = \frac{3{,}000 \times .5 \times 12}{.0833 \times 4} = 54{,}216 \text{ lbs. per sq. in.}$$

This is much greater than the breaking strength of the iron which is 24,000 lbs. per sq. in., and is accounted for by the fact that the stress decreases from 54,216 lbs. at the outside to zero at the center of the bar.

• • •

Question.—How high could a brick wall 17 inches thick be safely built on two 12-inch I beams supported at points 10 feet apart?

Answer.—To find total distributed load, use formula $\frac{M}{S} = \frac{I}{C}$.

M for uniformly distributed load $= \frac{PC}{8}$, and formula becomes $P = \frac{I}{C} \times \frac{8S}{l}$

I = 245.9 (from hand book) and for two beams = 245.9 × 2 = 491.8; S = 60,000.

Applying safety factor of .4, this becomes $\frac{60{,}000}{4} = 15{,}000$ lbs. per sq. in.

C = 6 in.; l = 10×12 = 120 inches.

$$P = \frac{491.8}{6} \times \frac{8 \times 15000}{120} = 81{,}965 \text{ lbs.}$$

One foot of 17-inch brick wall, 10 ft. long, gives $\frac{17}{12} \times 10 \times 1 = 14.166$ cu. ft., and this at 120 lbs. per cu. ft. gives 14.166×120 = 1,699.92 lbs. per foot of wall.

Permissible height of wall then is $\frac{81{,}965}{1{,}699.92} = 48.2$ feet.

• • •

Question. — Considering an engine crank pin as being supported at one end and having the load applied at the middle point of the overhang, what would be the diameter of a pin seven inches long if required to take a thrust of 72,000 lbs.?

Answer—Use formula $\frac{M}{S} = \frac{I}{C}$

M for cantilever=Pl, where l=length and P the concentrated load. Length in

this case is $\frac{7}{2}$ = 3.5 in.; M = 72000 × 3.5 = 252,000 lbs.; S = 64,000 lbs. Applying safety factor of 8, this becomes $\frac{64,000}{8} = 8,000$ lbs.

I = Moment of inertia which for a round section is .049d⁴ where d = diameter, $c = \frac{d}{2}$. It is required to find (d).

Formula becomes $\frac{252,000}{8,000} \times \frac{.049d^4}{\frac{d_2}{2}}$

$= \frac{252,000}{8,000} \times .098d^3$ or $d^3 = \frac{252,000}{8,000 \times .098}$

or $d^3 = 321.4$, or d = 6.85, or, say, 6¾ in.

• • •

Question.—Considering the load as being applied at a point ½ inch from the root of a 3-pitch gear tooth and the base of the tooth to be ⅝ in. thick, how wide should the face of the gear be in order that the tooth may withstand a pressure of 16,000 lbs.?

Answer—Using the beam formula $\frac{M}{S} = \frac{I}{C}$

M for cantilever $= \frac{Pl}{8}$; $I = \frac{bd^3}{12}$ for a section 1 in. long $= \frac{1 \times \frac{5}{8}^3}{12} = \frac{1 \times .625^3}{12}$

= .0203.

S = 20,000, which, for a safety factor of 10, becomes 2,000 lbs. per sq. in.; $c = \frac{.625}{2} = .312$.

$P = \frac{I \times 8 \times S}{1 \times C} = \frac{.0203 \times 8 \times 2000}{.5 \times .312} = 2,082$ lbs.

If each inch of tooth length sustain 2,082 lbs., the length necessary to sustain 16,000 lbs. will be $\frac{16,000}{2,082} = 7.68$ in., say, 8 in.

• • •

Question.—What load would a steel tube, 4 in. outside diameter and 3 in. inside diameter, support at the centre of a span of 4 ft.? What difference would it make if this same amount of metal were given the form of a rectangular beam of the same depth?

Answer.—Formula $\frac{M}{S} = \frac{I}{C}$

$M = \frac{Pl}{4}$ and formula becomes

$P = \frac{I \times S \times 4}{C \times 1}$

$I = .049 (d^4 - d_1^4)$ where d = outside diameter and d_1 = inside diameter $I = .049 (4^4 - 3^4) = 8.575$.

S = 60,000; C = 2 in.; l = 4 × 12 = 48 in.

$P = \frac{8.575 \times 60,000 \times 4}{2 \times 48} = 21,437.5$ lbs.

Cross sectional area = 5.497 sq. in.

Thickness of beam having same sectional area and height would be $\frac{5.497}{4}$ = 1.374 in.

For a cross section 1.374 × 4, $I = \frac{1.374 \times 4^3}{12}$ = 7.328.

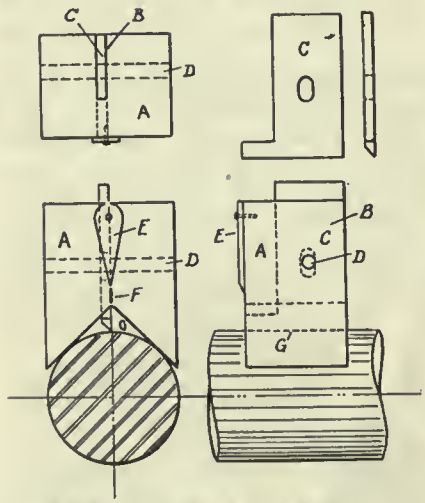
$P = \frac{7.328 \times 60000 \times 4}{2 \times 48} = 18,320$ lbs.,

or the latter is 15 per cent. weaker.

A SUGGESTED CENTRE FINDER

By James E. Cooley.

A VERY useful device for finding the centre for splines, broaches or holes in shafts or any cylindrical piece when set up in a machine vise, etc., is here described .In the accompanying cut, A, is a small V-block, 1 in. wide, ¾ in. thick, and 1½ in. long, having a slot 1/16 in.



CENTER FINDER FOR KEYWAYS.

wide cut through it, as at B, into which is fitted a sheet steel blade, C, 1/16 in. thick and 1¾ in. long. The blade is held in the block through an elongated hole with a pin D, on which it can slide up and down. On the front side of the block A is hung a small pointer, E, which swings on a pin, as shown. A short indicator line, is made on the block, as at F.

The method of using this to find the centre of the work is to place the block on the shaft so that the pointer E is directly central with the line F, and then with a long sharp-pointed instrument, as a scratch-awl, scribe a line along the edge of the blade, as at G.

EXPERIMENTS WITH CASE HARDENING.

A PAPER by Professor R. Baumann, read before the meeting of the German Naval Architects, referred to the fact that the superficial addition of carbon to parts of machinery subject to wear produced conditions similar to those of the encasing of a soft tough core of metal in a sleeve of harder but brittle metal. The object in view was the combination of these qualities in a finished working part, but it was a matter for investigation in how far the one quality suffered at the expense of the other. If the hard exterior cracked under tension, the inner material had not only to do all the work, but extra local strains were set up in it at the crack.

Test Features.

Tensile tests had been made on metals with and without case-hardening and at different temperatures. The tests had been extended to materials heated and quenched at temperatures of 200° C., 400° C., and 650° C respectively, and to others that had been slowly annealed. The materials treated were ordinary steel, nickel steel for case-hardening, and chrome nickel steel also for case-hardening. The tensile test samples were 15 mm. in diameter and were case-hardened to a not very uniform average depth of 1 mm. to 1½ mm. Notched bar and other tests were applied.

Under the bending test, pieces of sufficient length and of not very deep cementation, developed numerous cracks. Where the material was not tough, the sample broke directly a crack appeared. In the tensile tests made at ordinary temperatures, the cracking of the cemented outer layer caused the sample to break. Contrary to previous expectation, the same thing happened in tests at high temperatures also.

In most of the case-hardened samples, the fractures were at right angles to the axis, but in samples in which quenching had taken place at 40° C. they were generally diagonal. One of the latter reached a test load several times as great as those withstood by any of the other samples, and to what favorable circumstances this was due was a matter for speculation.

Several of the samples, polished and etched, showed the carbon gradually increasing in quantity towards the edges without any sharp line of demarcation. The special steel samples showed a much finer grain than the iron samples, the transition from the case-hardened layer

to the unhardened core being here still more gradual and regular. The Brinell ball pressure test, which in some cases had a tendency to break through the hard crust, gave good results with the special steels also. Under the tensile tests, the uncase-hardened samples that were annealed had an elongation of 31.8 per cent., and when hardened and quenched, they stretched from 5.4 to 5 per cent. only, this being due to the circumstance that the surface cracked and the resistance of the whole then collapsed. The hardened samples thus showed less tensile strength than the unhardened samples. In the diagrams of stress and elongation shown to the meeting, the lines for the case-hardened samples curved upwards to the point of fracture without the appearance of rapid yield. Diagrams for case-hardened and uncasehardened materials showed permanent set at points for the former at something like half the loads at which it appeared in the annealed, but otherwise untreated, material.

Permanent Set Point.

To keep the permanent set point as high as possible, the quenching must be done at sufficiently high temperature. Case-hardened nickel steel quenched at 400 deg. C. broke at 8,000 kilos per square centimetre, and up to 4,000 kilos per square centimetre showed little permanent set. When annealed it broke at 4,000 kilos per square centimetre, the permanent set being, up to this point, only slight. Quenched at 200 deg. C. it showed considerably more permanent set, and broke at 3,500 kilos per square centimetre. Uncase-hardened nickel steel broke at 3,500 kilos per square centimetre when annealed. When quenched at 200 deg. C. it broke at about 8,000 kilos per square centimetre, with little more than half the permanent set of the case-hardened sample quenched at 400 deg. C., which broke at about the same load. Comparative tests with case-hardened and uncase-hardened chrome nickel steel showed peculiarities similar to those of the nickel steel. The former broke at loads between 3,000 kilos and 4,000 kilos and the latter at loads between 3,000 kilos, and a little above 5,000 kilos per square centimetre.

Reduction of Ductility.

A series of diagrams giving the units of work required in the notched bar test at various temperatures illustrated the considerable reduction of ductility due to case-hardening. At temperatures of about 500 deg. C., the upper limit in the diagrams, a considerable improvement was, in the case of the steel samples, observable.

Noteworthy was the brittleness at low temperatures. Case-hardened nickel steel samples quenched at 200 deg. C. again showed greater elongation than the mild steel samples. Brittleness at low temperatures was not here manifested; in general, the samples broke after a much greater expenditure of work. Samples quenched at high temperatures —up to 650 deg. C.—in several cases behaved remarkably well. The results for chrome nickel case-hardened steel samples were much like those given by nickel steel. The fractures showed the coarsest grain to belong to the mild steel samples. Their appearance seemed to show that the treatment accorded to them had not been the most suitable. Spare samples subsequently heated up to 880 deg. C., cooled again in water and quenched at 200 deg. C., gave better results. Bending tests gave results which also enabled a judgment to be formed as to the toughness of the material treated. In general, the various tests carried out were thought to show:

(1)—The superiority of the special steels for the purpose in view.

(2)—The importance of the treatment of the material.

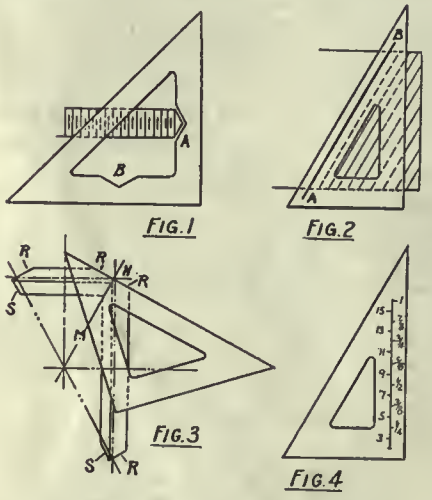
(3)—That the toughness of the core material came into play only to a limited extent.

In conclusion, the author recommended that tests be made in particular cases to ascertain whether case-hardening or the choice of a special steel material would be more suitable for parts subject to considerable wear.

TRANSPARENT TRIANGLE KINKS

By J. E. Cooley.

WHEN inking in the bottom of a hole or the end of a screw on a drawing it is necessary to draw one line first, and



TRANSPARENT TRIANGLE KINKS.

then wait till the ink dries before drawing the other, as the triangle has to rest on one of the lines. If the angle of the point, 30°, is made on the triangle, as at A and B, Fig. 1, for both horizontal and vertical holes and screws, the two lines can then be inked in without any trouble.

A simple method for penciling-in even-spaced section lines is shown in the sketch at Fig. 2. Instead of drawing-in lines one back of the other, these are drawn one ahead of the other. This is accomplished by making an inked guide line on the triangle, as A to B. This line is placed over the corner or starting point on the drawing, and the first line is drawn along the front edge of the triangle. The triangle is then moved forward till the guide-line is even with the first line, and the second line is then drawn. As seen in the sketch, the first line made is C, then D, and so on. The lines can be inked in or traced over in the usual way.

When laying out bevel gears on a drawing it is quite difficult to draw the bevel line R on the back face. This line is at right angles to lines that intersect the pitch circle, not the line S, or the front face. It is on this line that the top and bottom of the tooth is determined. If an inked guide-line, M to N, be made on the triangle at right angles to the straight-edge and placed on these intersecting lines, the line R is easily drawn.

Another suggestion is shown in Fig. 4 An inked line is marked off into several divisions, as 3/16, ¼, etc., and used for setting dividers, compasses, etc.

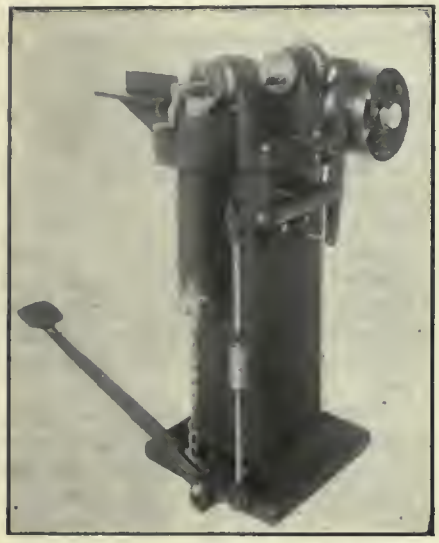
Workmen's Goggles.—An effort to secure the proper goggle for workmen subject to the intense glare of incandescent metals has been undertaken by the F. W. King Optical Co., Cleveland, Ohio. It has been found that the smoked and blue glasses commonly used defeat their very purpose of minimizing eye strain. Two kinds of light rays are regarded as particularly injurious to the eyes, the chemical or ultra violet rays, which have a deteriorating action on the tissues, and the heat or red rays which by their intense energy are probably the chief cause of eye fatigue. Smoked or blue glasses offer no resistance to the former, it is claimed, and are therefore of no benefit except to exclude much of the glare; while red, orange and similar glasses transmit the very harmful heat rays. In order to make the ideal goggle, it is held to be necessary first to cut off the invisible violet rays and then reduce the visible spectrum so as to absorb heat or energy rays to a point that produces no eye strain whatever. Of all the colors, a yellow-green seems best to accomplish this. It not only reduces the light to the limits desired, but it also distorts images less than any other. Moreover, the variation of brightness of incandescent metals with temperature appears relatively the same through this kind of glass as through uncolored glass.

PROGRESS IN NEW EQUIPMENT

A Record of New and Improved Machinery and Accessories for the Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

COPPER COIL FORMING MACHINES

THE machine shown in illustration was designed to coil copper field coils for automatic lighting systems, taking the copper in strips and coiling it together with a strip of insulation on a rectangular arbor. The copper strip is not only cut to length, but has a right-angle bend at one end, which is used for dogging purposes. A powerful spring keeps the work against the arbor and is controlled by a foot treadle. The machine trips automatically on the completion of three revolutions of the spindle. Coils are stripped off the arbor by the turning of the crank handle shown in center of spindle. The next strip is put in place and the machine will start immediately on removing foot from the treadle. Other metals can be used in place of copper, and the number of coils and shape can be changed to suit other work.



COPPER COIL FORMING MACHINE.

The machine is manufactured by the Garvin Machine Co., of New York City, and weighs 66 lbs. crated.

ROTARY CENTER INDICATOR.

THE Rotary Center Indicator is an instrument designed to quickly and accurately indicate the center or axis of any rotating spindle or shaft. It is a small and compact instrument, strongly built and not likely to be injured by careless handling. It is a positive and accurate tool and will be found useful by those engaged in laying out and boring holes in jigs, tools and machine parts. When used in connection with the Casler offset boring head it enables the operator to accurtely locate holes without removing the boring head from the spindle of the machine.

It consists of a body or shank A which may be gripped in the chuck of the boring head or a drawing in collet in the spindle. A pointer B is held against the face plate C by a coil spring concealed in the body of the tool. The contact surfaces between the pointer and face plate are hardened, ground and lapped to a true flat surface. The pointer is free to float or slide in any direction over the surface of the face plate, and the head D is ground to a diameter of ¼ in.

When used in the chuck of a boring head, the chuck is brought concentric with the head. It is not necessary that the body A of the indicator run true as it is designed for just such conditions. The pointer B is brought next to a finished surface F near the center of the hole to be bored, being moved to one side of the face plate C, so that when the spindle is rotated the pointer will "wobble" or describe a circle.

The spindle is allowed to rotate, and as the table E carrying the work W is raised the head D of the pointer will alternately strike the finished surface F of the work and then recede, the distance which the head D recedes growing less and less as the work is raised. At the same time, the pointer B approaches nearer to the center or axis of the spindle on which the indicator is mounted. The table is raised until the pointer runs true or does not recede from the work. If the table is raised 1-10,000 in. too far, the pointer B will quickly creep to the left or right depending on the direction of rotation of the spindle. When this happens the table is lowered, the pointer moved toward the edge of the face plate and the table raises again until the pointer runs true.

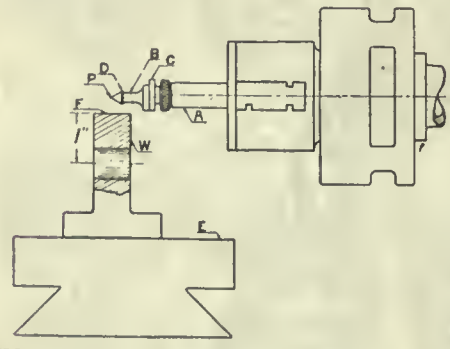


FIG. 1. ROTARY CENTER INDICATOR.

The graduated dial indicating vertical movement of the table can now be set to zero, and as the diameter of the head D is ¼ in., the table can be raised ⅛ in., which will bring the the center of the spindle in line with the finished surface of the work and a further movement of 1 in. will bring the spindle on a horizontal line passing through the center of the hole to be bored as indicated by the illustration. It is obvious that lateral distances can be ganged in like manner by setting the pointer B with any vertical finished surface on the work.

The point P is intended for use when a hole is to be bored concentric with a center punch mark on the work. The pointer C is then made to run true by bringing it against any flat surface on the table or work, and afterwards bringing the pointer concentric with the center punch mark on the work. When used in this manner the face plate B has a limited movement in the body A against a compression spring which allows the point P to be forced into the center punch mark without danger of injuring the indicator.

Fig. 2 shows a means of testing the accuracy of the device by use of a micrometer. The micrometer is opened about ¾ in.; and the screw can be gradually brought towards the pointer until it runs true. A slight additional movement of the screw will throw the pointer to one side as explained above. In testing the accuracy, it should be borne in mind that it is sensitive to 1-10,000 in., and if the spindle bearings are worn or the machine gear driven, it may be necessary to run the spindle at a low speed, otherwise the vibration of the spindle will destroy the accuracy of the device.

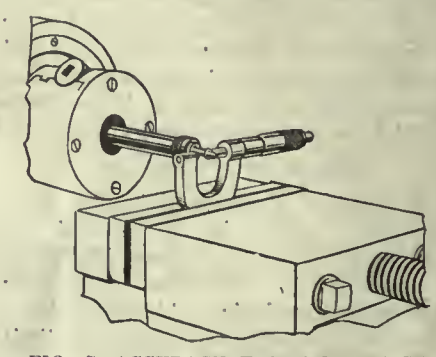

FIG. 2. ACCURACY TESTING DEVICE.

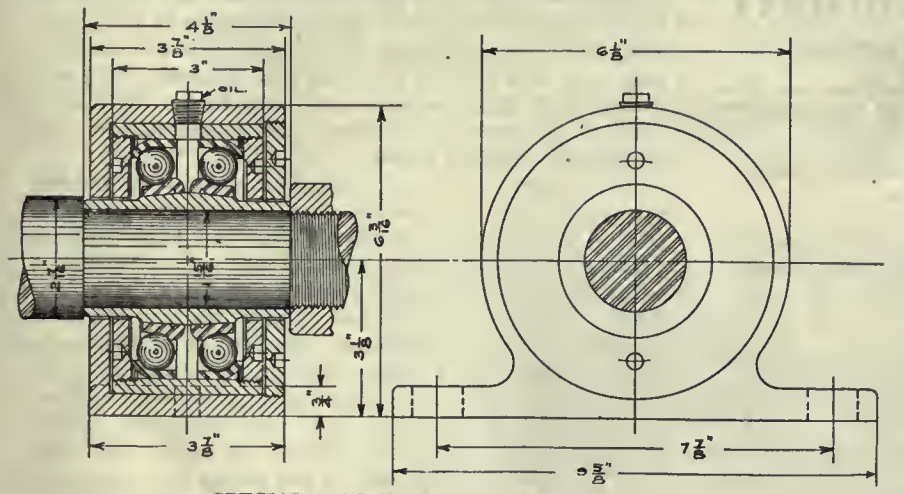
The Marvin & Casler, Canastota, N.Y., are the manufacturers of this apparatus.

18-IN. DOUBLE BALL BEARING DISC GRINDER.

THE Ford-Smith Machine Co., Hamilton, Ont., have recently put on the market a new 18-in. disc grinder equipped with ball bearings as made by the Chapman Double Ball Bearing Co., Toronto, instead of the regular adjustable phosphor bronze bearings. It will be noted from the



SPECIAL DISC GRINDER BALL BEARING.

line drawing that each bearing has a double ball race and is adjustable for any slight wear that may take place, while a good idea of the general design of the grinder can be had from the half-tone illustration. The tables are of the regular standard swing type, and call for no special mention, except that they are supplied with lever feed or otherwise to suit customers' special requirements.

A full line of disc grinders has now been added by the company to their previously complete line of bench, floor, tool and swing grinders, and their early production of a new line of ball bearing grinders, ball bearing countershafts and loose pulleys we hope to record in an early issue.

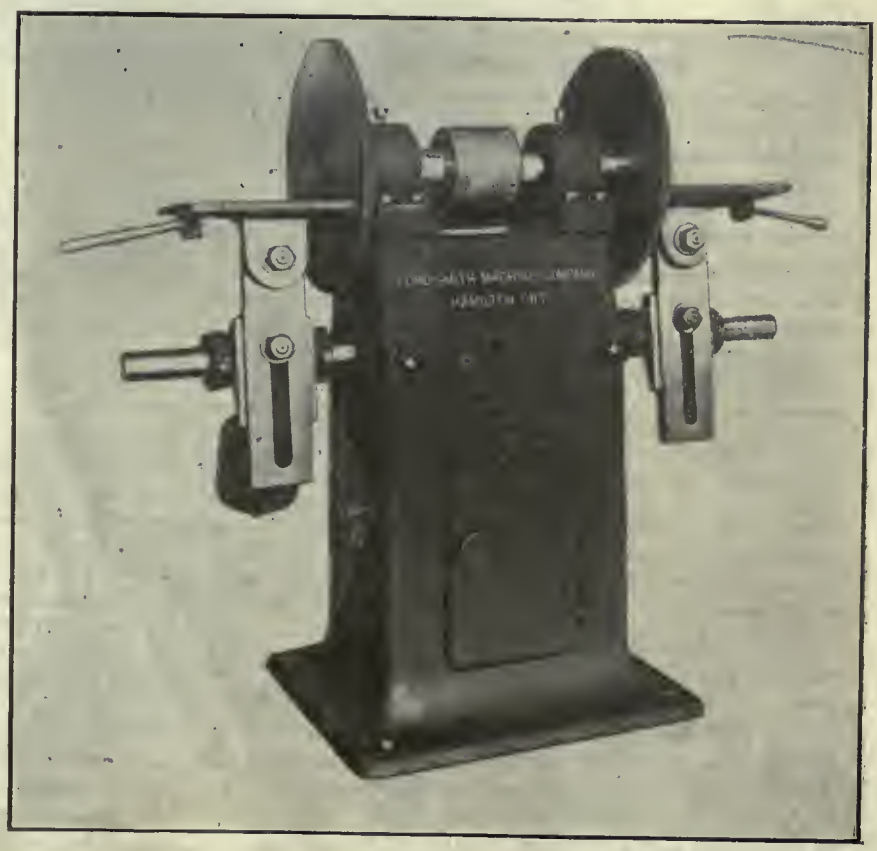
Miscellaneous

Alexander Gibb, St. Nicholas Building, Montreal, has secured the Canadian agency for Anti-Corrosive Paints and Anti-Fouling Composition, manufactured by Suter & Rathjens Composition Co., London, Eng. Several large orders of same have been sold already to be used on railway construction and marine work.

The Independent Pneumatic Tool Co., of Chicago, Ill., and New York, have leased the two-storey building at No. 334 St. James Street, Montreal, Que., and have arranged to open a branch store, where their Canadian business will be transacted after August 9. A complete line of "Thor" pneumatic tools, electric drills, accessories, and spare parts will be carried in stock for immediate delivery on orders in Canada. W. H. Rosevear, who has been prominent in the railway supply and machine tool business in Canada, has been engaged as manager.

The Canadian Steel Products Co., 227-229 Wellington Street, Montreal, announce that they have completed the equipping of their factory for the manufacture of sheet steel, flush and service cabinets for switches, cut-outs and panel boards. The factory will be under the general managership of S. A. Ungerleider, who has had extensive experience in the United States. The machinery and tools are all of the most modern and improved type. They will also manufacture time switches, sheet steel shop equipment, steel shelving and lockers, portable garages and other sheet steel and electrical specialties.

U.S. Firms Oversea.—To be in a better position to satisfy an increasing number of European customers, the Potter & Johnston Machine Co., Pawtucket, R.I., and the Windsor Machine Co., Windsor, Vermont, recently decided to erect works at Tyseley, Birmingham, England, under the name of Potter, Johnston & Gridley, Ltd., for the manufacture of Potter & Johnston automatic chucking machines, automatic center turning machines, automatic milling machines, automatic cutting-off machines, universal shaping machines and shaving machines; also the Gridley four-spindle automatic bar machines and automatic multiple spindle drilling machines, all of the above machines being covered by British and foreign patents. In addition to the manufacture of the machines mentioned, there will be a specially organized tool-making department for the rapid supply of tools required by European customers, which will avoid the delays caused in transport when shipped from the American shops. The new works are now in course of construction and will be ready for occupancy in the coming fall.



18-INCH BALL-BEARING DISC GRINDER.

THE EDUCATION OF THE FOREMAN.

IT has been truthfully said that judicious travel gives the broadest education possible. It should also be realized by plant owners and managers that no education is too broad for a foreman worthy of the name. No man is more confined to a narrow sphere than the foreman who is kept at home and thoroughly impressed with the fact that the wheels would cease to hum were he to leave his post. Friction with men and dissatisfaction with work can, in a majority of cases, be traced to a lack of diplomacy or a chronic disagreeable narrowness of the foreman.

Several of the larger Canadian manufacturers have gone so far as to send representatives to conventions of men engaged in similar classes of work. The writer has in mind one case of a foreman who had not been more than 140 miles from his shop in nine years and who, upon returning from a gathering involving the whole of America said there was nothing there for him to learn. Is it surprising that this man's manager should be discouraged with the instructive advantages of conventions or the broadening effect of travel?

The experience of men whose business it is to find out the newest and best methods of accomplishing mechanical ends as well as to keep abreast of improved manufacturing processes has proved that conventions and, particularly, conventions alone, do not furnish the best returns for the least expenditure of time and money. By far the most fruitful sources of education for foremen are visits to similar plants and association with technical journals. The visiting should be carried out systematically and in a way that will keep the visitor thoroughly in touch with himself as others see him.

To derive the full benefit of the money thus expended, the manager must choose his direct subordinates wisely and must have powerful means of holding them, for this manner of education not only increases their usefulness of their own firm, but makes them a valuable acquisition to others. This is done by different corporations in as many different ways. The granting of a share of stock or a superior financial remuneration has been successful to a degree, but far more important than these will always be those personal qualities of the management which to the utmost degree have characterized all great leaders of men.

PRACTICAL MANAGEMENT.

OUT of the recent researches into scientific management, cost engineering, production engineering, motion study, etc., there will, no doubt, survive a practical application which will be as familiar to the foreman and mechanic as the present appellations of economical manufacturing are mysterious. Already the simplifications are beginning to appear which promise that, in the near future, a large part of scientific management will be resolved into a remarkably few comparatively elementary rules of procedure on the part of operatives and their direct superiors.

Manufacturers have perfected and solved the scientific problems of the unit system. Examples of this may be seen in the dispatch with which a mighty steamer can be turned out by some of the British ship yards. The multiple system of to-day to which so called scientific management has been applied, has by no means, reached the stage of comparative perfection which has been enjoyed by the unit system for a number of years.

Production engineering, in the case of the unit system, has become part of the natural and prescribed procedure of workmen and supervisors, and just as the rational habits of men necessitated by the multiple system become part of their natural course, so the production engineer will become superflous and will disappear. Efficiency of the workman, in the former case is measured more or less by the number of different branches of work to which he can successfully apply himself, while in the latter, the economical workman concentrates his faculties upon the smallest element possible.

INDUSTRIAL NOTABILITIES--No. 44

HON. Erskine Henry Bronson, president the Bronson Co., Water Powers and Manufacturers of Ground Wood Pulp, Ottawa; president Ottawa Improvement Co.; vice-president Ottawa Light, Heat and Power Co.; president Ottawa Power Co., and director Ottawa Electric Co., was born at Bolton, Warren County, N.Y., Sept. 12, 1844, son of the late Henry Franklin Bronson, Warren County, N.Y., who, in 1853, came to Ottawa where he was the pioneer of the sawn lumber trade with the American market, and Editha (Pierce) Bronson.

He was educated at the Grammar School, Ottawa, and at Sandy Hill, N.J., after which he joined the Bronson & Weston Lumber Co., acquiring therein an interest in 1867. On the death of his father in 1889 he became president of the Company.

HON. ERSKINE HENRY BRONSON.

Among the many activities to which the Hon. E. H. Bronson has devoted himself may be mentioned the following:—An originator of the Ottawa Electric Co.; member Ottawa School Board for 14 years; ex-Trustee Queen's University, Kingston, Ont; member Ottawa Council, 1870-1878; chairman Finance Committee Ottawa City Council; member Ontario Legislature for Ottawa 1886-1898; member Mowat and Hardy Governments without portfolio, 1890; and unsuccessful candidate to House of Commons for Carleton in 1882. His name has been mentioned several times in connection with a Senatorship.

In 1874 he married Ella H. Webster, daughter of the late professor N. B. Webster, of Norfolk, Va., one son and one daughter being born of the union.

Hon. E. H. Bronson is a Presbyterian in religion, and the family residence is 75 Bronson Ave., Ottawa, Ont.

WILL OIL REPLACE COAL AS FUEL?

By W. J. Dick.

THE world's production of crude petroleum in 1912 amounted to about 52,921,750 tons; the sources, respective quantities and percentages were as follows:

Country.	Net Tons.
United States	32,897,060
Russia	10,174,560
Mexico	2,910,000
Roumania	1,987,360
Dutch East Indies	1,672,000
Galicia	1,298,620
India	1,101,450
Canada	38,750
Other countries	841,250

If the whole of this crude petroleum were employed as fuel in steam-raising it would not replace, allowing for its higher thermal efficiency, much more than 5½ per cent. of the world's output of coal, whilst if used in internal combustion engines it would be equivalent, as a source of power, to about 16 per cent. of the coal. Only a small proportion, however, of the crude petroleum can be regarded as available for use as a source of power, for by far the larger part is in demand as an illuminating agent and as a lubricant for machinery.

As the United States produces over 62 per cent. of the world's production of petroleum, it is interesting to note that Dr. Day, of the United States Geological Survey, considers that, at the present rate of increase of the output of petroleum, the known oilfields of the United States will, on the basis of the minimum quantity of oil obtainable, be exhausted by the year 1935, while, even if only the present output were maintained, the supply would, on the same basis, not last more than nineteen years.

In many countries there are, no doubt, vast tracts of undeveloped petroliferous territory, but only drilling can determine this. Even if the available deposits were far larger than there is reason to believe them to be, the cost of doubling the present output would be great. In view of these circumstances, it is not probable that there can be any general substitution of petroleum for coal as a source of power, although there is undoubtedly opportunity for making provision for a large use of liquid fuel for certain purposes in which its advantages are conspicuous.

Toronto, Ont.—Two of the lighters designed and constructed for the Department of Railways and Canals left Polson's Iron Works on July 14 for Port Nelson, on Hudson Bay. The journey is over 4,000 miles, and when the boats reach their destination they will be used for lightering ocean-going vessels which draw too much water, to allow them to discharge cargoes at the present wharf.

Windsor, Ont.—The Dominion Government has just completed a new 655-ft. cement wharf here at a cost of approximately $60,000, and has begun the erection of a reinforced cement warehouse on it at a cost of $10,000

Ottawa, Ont.—The rather unusual expedient of forwarding a Government boat by train is being resorted to in the case of the George H. Bradbury, the new boat to be used for departmental services on Lake Winnipeg. The Bradbury has been built at the marine yards at Sorel, and is being shipped west in sections. The parts will be reassembled and erected at Selkirk under direction of the marine superintendent from Sorel.

Montreal, Que.—An elevator with a capacity of two million bushels is likely to be erected in the port of Montreal at an early date. It is understood that plans are being made for the erection of another huge concrete structure to relieve the congestion which is apparent in the port every summer. The new elevator will be an addition to No. 1, the elevator near the White Star wharf. It will give No. 1 a capacity of over 4,500,000 bushels.

The General Market Conditions and Tendencies

This section sets forth the views and observations of men qualified to judge the outlook and with whom we are in close touch through provincial correspondents.

Montreal, Que., July 20, 1914.—There has been very little change in the business outlook, and things generally are just about the same as last week. Trade is still very dull in machinery lines especially. While there is a disposition on the part of most people to look hopefully to the future, it has to be admitted that there is not much likelihood of conditions improving for some time yet, certainly not before the fall.

During the week nothing big in the construction line has materialized, but, considering the condition of business, local contractors have had a good year. There has, however, been very little doing in construction machinery, the tendency being to make use of old equipment for this year's work.

Metals.

There has been little or no change in the metal market. Small orders are still the rule, although one house reports a couple of big contracts booked last week. Sterling quotations to-day are:—Tin, spot, £145 17s. 6d.; futures, £147; copper, spot, £61 2s. 6d; futures, £61 10s. 7d.; lead, £19; spelter, £21 10s.

Other prices remain unchanged.

Toronto, Ont., July 21, 1914.—There is little change in business conditions this week, although signs of a revival are becoming more evident, and prospects for an improvement in trade this fall appear brighter. Some authorities consider that the outlook is more encouraging now than it has been for some time past. This optimism may perhaps be accounted for to some extent by the crop reports, which continue to be, on the whole, favorable. Many manufacturers are still operating their plants on short time, and in some cases with a reduced working force. A spirit of caution must of necessity be adopted until the outlook improves and the development of the country proceeds on its normal course. It is more than probable that the natural development, which has been retarded by the depression, will, when once resumed, progress on even a larger scale than formerly, and we hope on a sounder basis.

There have been reports circulating recently to the effect that the C.N.R. has placed an order for passenger cars, amounting to $500,000, with the Canadian Car and Foundry Co., Montreal, and an order for ten baggage cars with the National Steel Car Co., Hamilton. While we understand that the C.N.R. will place substantial orders for cars, we do not believe that any contracts have actually been signed as yet.

Steel Market.

Little improvement is noticeable in the steel market this week, conditions generally being quiet. A more optimistic spirit, however, is becoming general, and there are indications that business will improve somewhat in the near future. A better condition of affairs seems to be prevalent in the United States, where a distinct improvement has come over the iron and steel situations. It is thought by some that the turning point has been passed, and that the steel market is recovering, anticipating a return to more prosperous conditions. Although some contracts have been placed at slightly better prices, the mills do not expect much advance this year.

An interesting situation has been revealed in London, England, recently. The R. D. Wood Co., of Philadelphia, quoted 25 cents a ton less than an English syndicate on a large quantity of cast iron pipe for the city of London. Public sentiment and pressure was, however, brought to bear on the authorities, with the result that the order was not placed with the R. D. Wood Co., notwithstanding the fact that they were the lowest bidders.

Pig Iron.

The pig iron market is quiet, although there are signs of a slight improvement materializing by the fall. Prices are nominally unchanged, and it is hardly probable that there will be much of an advance for some time. The pig iron market in the United States is quiet, and production has, if anything, been curtailed.

Machine Tools.

The condition of the machine tool market has not changed to any appreciable extent, and current business is still confined to small sales. Some dealers report an improvement in the number of inquiries being received. The Canada Wire and Cable Co. are in the market for a number of tools for their new plant at Leaside, near here. The possibility of the railways coming into the market this year is getting remote, and the ultimate realization of accumulating prospects is about the only hope left.

Metal Markets.

The metal markets have an improved tone this week, and more business is passing, which is satisfactory, as July is usually a very quiet month. There has been no change in prices, the majority of metals keeping steady.

Ottawa, Ont., July 20, 1914.—The Canadian Northern trust deed is now finally signed, and Sir William Mackenzie is in a position to go on the market for needed money. It is believed that it will have a tendency to relieve the general business depression. The Grand Trunk trust deed, by which the Government guarantees bonds for that road to the extent of $16,000,000, is still hanging fire. There is a general impression at Ottawa that the Government is using pressure to have the Grand Trunk Pacific accept the award of the arbitration board in regard to its machinists in its western shops. The Government can scarcely indefinitely refuse to close up the transaction on this ground, but it can postpone the matter for a while with a view to exerting pressure on the company. This is apparently what is being done.

With a continually decreasing revenue the Finance Minister will evidently have to do some pruning if he is going to come out on the right side of the ledger this coming year. The drop in revenue for the month of June was some two million dollars. For the twelve months this would mean a decrease in revenues of some twenty-four million dollars. However, the difference between the receipts for the latter part of this year and the corresponding period of last year will not likely be so marked. The first part of 1913 everything was booming as far as revenues were concerned, and the financial depression had not started to affect the custom receipts. It was about this time last year that revenues commenced to drop, and it would not be surprising if the revenues from now on for 1914 would be higher than the same months of 1913.

Sir George Foster left to-day for Rimouski, where he meets the members of the Dominions' Royal Commission, who are to hold sessions in Canada and Newfoundland. They go first to Newfoundland, landing at Sydney on August 3, when they start a tour of the Dominion, closing about the middle of October in Victoria.

The Dominions' Royal Commission was first suggested by Sir Wilfrid Laurier at the last Imperial conference held in 1911. Sir Wilfrid moved a resolution suggesting the appointment of a commission to study the trade problems of the Empire and allied questions with a view to closer co-operation. The commission was appointed the following year by the Imperial Government, and at once started its inquiry. It was given a wide scope. It first held sittings in England and then visited New Zealand and Australia, and this spring went to South Africa. Canada will be the last place visited, as only the self-governed parts of the Empire are included. The

report will be prepared this winter, and will be presented to the Imperial Conference being held next year.

The itinerary of the commission in Eastern Canada is as follows:—Halifax, August 5; St. John, August 11; Charlottetown, August 17; Quebec, August 20 to 22; Montreal, August 24 to 26; Ottawa, August 28 to 29, and Toronto early in September. The commissioners will travel westward via the Great Lakes and Winnipeg, concluding their sittings in Vancouver about October 10. Ocean freights, shipping and harbor facilities and cable and postal communication will form the chief matters of consideration. Every effort will be made to prepare an interim report before their departure.

The importance of the inquiry to the business and commercial interests of Canada can scarcely be over-estimated.

CANADIAN PULPWOOD EXPORT DECREASE.

STATISTICS of the pulpwood consumption during 1913, compiled by the Forestry Branch of the Department of the Interior show that the forty-eight active firms in the Dominion consumed in their mills a total of 1,109,034 cords of pulpwood valued at the mill at $7,243,368. A total of 1,035,030 cords of unmanufactured pulpwood, valued at $7,070,571, was exported to the United States bringing the total production up to 2,144,064 cords, valued at $14,313,939. The following table shows the distribution of the manufacturing trade in the various provinces, value, etc.:—

	Active Firms.	No. of Cords.	Total Value.
Canada	48	1,109,034	$7,243,368
Quebec	26	629,934	4,107,689
Ontario	12	321,244	2,297,389
Brit. Columbia	2	84,173	401,218
New Brunswick	4	53,121	342,243
Nova Scotia.	4	20,562	94,829

The total quantity showed an increase of 28.1 per cent. over that of 1912, and average price of raw pulpwood at the mill increased by 51 cents a cord, making an increase of 38.9 per cent. in the total value of the material used in the industry. Quebec and Ontario still led the other provinces in 1913, but the feature of the returns so far as New Brunswick is concerned was that the province was in 1913 displaced from third place by British Columbia. There was an increase in each of the provinces except Nova Scotia, where the closing of four mills caused a decrease of 21.4 per cent. The increase in New Brunswick was 2.1 per cent. British Columbia showed an advance of 140 per cent.

The following table shows the kind of woods used and the values:—

	No. of Cords.	Total Value.
Total	1,109,034	$7,243,368
Spruce	754,858	5,104,221
Balsam Fir	283,292	1,806,911
Hemlock	47,360	201,480
Jack Pine	19,383	101,675
Poplar	4,141	29,081

The export of wood pulp from Canada decreased from 1912 to 1913 by 22.4 per cent. in spite of an increase of 25.2 per cent. in the quantity manufactured. This would seem to indicate increased activity in the domestic manufacture of paper. Decreases are to be noted in the exports of pulp to the United States, Great Britain and China. New Zealand did not import Canadian pulp in 1913. The only increase reported was in the export of chemical pulp to Japan. The United States still takes about two-thirds of our pulp, of which about 70 per cent. is ground wood. Great Britain takes a little less than a third of the total and her importations are almost entirely ground wood or mechanical pulp.

More Wood Pulp Imported

The imports of wood pulp into Canada in 1913 were valued at $356,862, as compared with $172,797 for 1912. This is an increase of over 100 per cent., the imports from the United States having more than tripled during 1913. The importation from Great Britain more than doubled, and those from Germany increased by over half those in 1912. The importations of wood pulp from Sweden decreased by 42.8 per cent. Pulp was imported from Norway and Switzerland in 1913, but not in the previous year. No pulp was imported from Austria Hungary in 1913. The United States in 1913 supplied over four-fifths of the total, as compared with over a half in 1912.

U.S. FOREIGN TRADE COUNCIL.

JAMES A. FARRELL, president of the United States Steel Corporation, has been named as chairman of the American Foreign Trade Council, and all sections of the country and many branches of industry, transportation and finance are represented among the members. Outlining the purpose of the council, Mr. Farrell said:

"The next great era in the economic development of the United States will be the extension of our foreign trade, and the formation of the Foreign Trade Council is a necessary preparation for this evolution in our business life. By gathering active and representative business men into such a body and co-operating with all elements in our oversea commerce, it is hoped to encourage every practical and sound policy designed to secure for us our share of the trade of the world's markets.

"The foreign trade of the United States is now valued at four and one-half billion dollars a year, of which two and one-half billion dollars represent exports. This trade has developed largely by reason of our natural resources and the individual enterprise of American industry, but without an American merchant marine, comprehensive national policy or commercial and industrial co-operation. The foreign trade is important as affecting American industrial enterprise and labor at home. On the other hand, it is not large enough to absorb all our manufacturing potentialities."

Trade Gossip

Laurie & Lamb, Montreal, have received an order from the Abitibi Pulp & Paper Co. for four 500 brake-horse-power Bellis & Morcom engines, to drive their paper machines by rope drive. The Alberta Government have also ordered a 180 brake-horse-power Bellis & Morcom engine, to be installed at the Ponoka Asylum.

Butterfield & Co., of Derby Line, Vt., and Rock Island, Que., are building an addition to their factory at Rock Island. The new building will be 185 feet long, 60 feet wide, and three-storeys high, of brick and concrete construction. A portion of the new building will be used for manufacturing twist drills and milling cutters. It is hoped the factory will be in operation by January 1, 1915.

Trade Commissioner's Report. — The report of his Majesty's Trade Commissioner to the Dominions of Canada and Newfoundland for the year 1913 has just been published. The report contains a survey of all lines of merchandise, as well as statistical tables dealing with the various trades, showing the value of the importation under the trade heading of the articles which are component parts of that particular trade. The report should be of considerable value to those dealing with British manufacturers and merchants, as well as to agents having or contemplating connection with United Kingdom manufacturers by reason of the comparison made in dollars of Great Britain's trade with the Dominion in comparison with the trade of other countries. Useful information is also given regarding the appointment of agents and the handling of products of British manufacture. The edition is limited, and application for copies, which will be supplied at the nominal fee of $1 each, postage paid, should be made immediately to his Majesty's Trade Commissioner, 5 Beaver Hall Square, Montreal, Que.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News.

Engineering

Smith's Falls, Ont.—T. G. Kyle has bought the foundry and other manufacturing establishments of the P. Kyle estate.

Kingston, Ont.—Fire in the engineering buildings at Queen's University on July 16 did $1,500 damage. It started over the boiler. One motor was destroyed and another damaged.

Stratford, Ont.—The Stratford Water Commissioners have decided to fall in line with the suggestion of the Hydro-Electric Commission and supplant the steam boilers with gasoline engines.

Weyburn, Sask.—Dr. E. M. Gratton, of the Dominion Odie Co., reports that an early start will be made on the construction of the foundry for this company. The building will be of brick, 50 x 50 feet.

Redcliff, Alta.—The Redcliff Ornamental Ironworks are supplying a considerable amount of ironwork to the new Regina College and the Douglas Building at Moose Jaw. Other industries in Redcliff are reported to be doing good business.

Redcliff, Alta.—The headquarters of the H. Kelly Heating & Plumbing Co. of Calgary is to be moved to Redcliff at once. This company employs 150 men, and now has some of the largest heating and plumbing contracts in the Western Province.

Woodstock, Ont.—Messrs. Wallace Gibson, W. S. Skillen, E. W. Mair, W. S. Sutton and E. R. Teed, all of Woodstock, are applying for incorporation as the Woodstock Foundry, Ltd., with an authorized capitalization of $40,000 and head office at Woodstock.

Hamilton, Ont.—An announcement was made on July 15 by Basil Magor, vice-president of the National Steel Car Co., that his concern had let the contract for an extensive addition to its passenger car department. It is reported that the company has secured large orders for equipment and passenger cars.

Victoria, B.C.—Damage estimated at between $4,000 and $5,000 was done to the pipe fabricating plant, operated by the Burrard Engineering Co., at Thetis Cove, Esquimalt Harbor, recently, when the inflammable material in the dipping tank became ignited. For an hour the fire raged, destroying the hoisting machinery, caulking shed, dipping tank and a large quantity of dipping compound, as well as several lengths of fabricated pipe.

Redcliff, Alta.—The Imperial Brass Mfg. Co., of Chicago, has closed a contract for a factory at Redcliff, and will commence construction at once. The buildings will be similar in equipment to the Chicago plant. They will be built of brick, and the plant will be in operation before winter sets in. The main buildings will be 40 x 150 feet, and employ at the start 50 men. The product will be brass and hardware specialties, pumps, valves, faucets, self-heating flat irons, etc.

CALL FOR NEW EQUIPMENT.

The Canada Wire and Cable Co., Toronto, Ont., are in the market for the following tools for their new plant at Leaside, near Toronto:—

One 2-spindle sensitive drill press.
One 2-wheel emery stand.
One 23-in. disc grinder, with press.
One No. 2 Brown & Sharpe universal milling machine, complete with attachments
One 18-in. crank shaper.
One 14-in. power hack saw.
One 14-in. Pratt & Whitney tool makers' lathe, complete with grinding attachment.
One 18-in. x 12-ft. engine lathe, complete with face plates and chucks.
One 24-in. planer.
One gap lathe to swing in gap 36 in., motor driven direct connected.
One power pipe threading machine, with complete set dies up to 6 in.
One drill grinder.
One arbor press.
One electric portable drill, 110 volt., 25 cycle, single phase.
One milling cutting grinder.

Walkerville, Ont.—The Ford Motor Company will erect a six-storey addition to the main factory building at a cost of $300,000. The new structure will be 195 x 200 feet and will be of similar construction to the main buildings. The first five floors will be used for factory purposes, while the top floor will be used for additional offices. The new addition will be erected on the site occupied by the old factory, now used as a shipping warehouse, fronting on Sandwich street. Work will begin at once.

Toronto, Ont.—A meeting of the creditors of the Berg Machinery Mfg. Co. was held at the office of James P. Langley McKinnon building, Toronto. The statement presented by the assignee showed nominal assets, after payment in full of its creditors, of $214,294.18. Messrs. Melville Bertram, J. Hardy, W. G. More, W. A. Hare and Fred Miller were appointed inspectors to co-operate with the assignee in winding up the estate. The creditors expressed themselves as anxious that those interested in the company should continue the business.

Vancouver, B.C.—An industry likely to prove of substantial value to Vancouver is about to be launched under the name of the British Columbia Steel Works, Ltd. The company, capitalized at $500,000, has associated with it as directors a number of well-known Vancouver business men consisting of the following:—Francis L. Leighton, general manager of the Vancouver Engineering Works, Ltd.; J. J. Banfield, Nicholas Thompson, David A. Smith, president of the D. A. Smith Co.; Geo. E. Graham, general manager of the Coquitlam Terminal Co. Arthur M. Valentine is secretary-treasurer. On a site of five acres, giving 300 feet of water frontage at Bridgeport, Lulu Island, the works will manufacture merchant bar, angles, rounds, flats, bolts, nuts and light rails from scrap which will include wrought iron, steel scrap, turnings, pipes, plates, shearings, etc. The new enterprise will require buildings and machinery to cost $100,000, and will give employment to a considerable number of hands when in full operation.

Electrical

Windsor, Ont.—The Hydro Commissioners have made arrangements to turn on the hydro current here on September 12, the opening day of the local industrial exhibition.

Developing Shop Efficiency Without Outside Expert Aid*

By H. Westbrook **

The study of shop efficiency has of late been so decked with the results of scientific research and the names of new professional callings as to be largely uninteresting to the average foreman and mechanic. The writer of the following paper, however, handles the subject from the practical man's point of view, and introduces, by the way, some simple and novel suggestions.

AS an introduction to the subject matter of this paper, the author wishes to point out that he does not pose as an efficiency engineer, business expert, industrial doctor or similarly titled individual, the idea being rather to deal with matters which every foreman can accomplish in his own organization in the direction of betterment, without the expenditure of large sums of money or the calling together of a board of directors to sanction some new policy. A number of the suggestions are, no doubt, painfully obvious to many, but I can assure you there are still many shops where some of them can be employed with profit.

What Does Efficiency Mean?

Efficiency means keen self-criticism; it means going into your shop and finding nothing there which is sacred or fixed; it means that methods employed six months ago may to-day be ancient history; it means forgetting traditions and the questioning of everything, including yourself, your methods and your knowledge. It means to make the work easy by doing away with unnecessary motions, thereby enabling a workman to employ all his time in doing productive work and not tiring himself performing labor not actually required or that can be equally as well or better performed by other means.

True efficiency is more interested in the study of the man than of the machine. Required to produce certain results, and given a choice between a factory equipped with modern tools, up-to-date appliances and a staff of disinterested men, or with an out-of-date equipment and a staff of good, loyal men, ready to co-operate and show what result from such a combination, I would most certainly choose the latter; but given the loyal men, the up-to-date equipment, and men directing things who could and would create and keep this attitude alive, then we would obtain the greatest efficiency.

The first requisite, then, for greatest efficiency, is to create a condition among your men where each one is as anxious as yourself to reduce to a minimum all unnecessary work, to be more willing to call attention to improvements than to have them pointed out to them. This is not an impossible condition, or even difficult to attain. I have in mind one shop, a piece-work one at that, where men are frequently suggesting that, if their particular job was to have the pattern slightly altered, or a certain tool or device supplied, they could do the job for 10 or 20 per cent. less. To have such a condition there must exist the greatest confidence between the foreman or superintendent and the men. We must get it into our heads that it is only possible to obtain the greatest degree of efficiency where we have the greatest degree of **co-operation** If the employer feels that greater efficiency is only a method by which he makes his workmen exert themselves very much more, entirely to the employer's gain, he had better stick to his present methods whatever they may be.

No Knowledge Monopoly.

The foreman should understand that the fact of his being foreman does not imply that he knows all there is to be known about everything that he is supposed to be boss of or supervisor over. He must not think or permit his men to believe that he thinks he has no more to learn. On the other hand, the machinist, blacksmith, carpenter, etc., must not be permitted to think that, because he is such, he knows everything there is to know concerning his branch of the trade; so I say again that the man most closely in touch with the directing of his men is the one to whom we must look to obtain the foregoing desirable results and the more successful he is in this, the more real value he is to his employer, and the better prepared he will be for advancement should it come to him.

I became more interested in this subject than I had hitherto been, although for years I had found myself being gradually attracted to it, on receiving a letter from a friend of mine, who at that time was superintendent of a large machine shop in another city. He had known that I was interested in the subject. For reference, I quote the following part of his letter:—

> "Things are so busy in the shop, I must either ask for more mechanics, more machines, work overtime, or go after my men harder. Now while I am sure they are just as fast a bunch if not faster than the average, my speeds and feeds up to the limit of high-speed steel, and they are loyal to me, and I do not wish to recommend engaging an **efficiency expert**, can you arrange to come over and visit me and knock around the shop for a week or two. I believe you could see things that I may have overlooked in my familiarity with them. Don't disturb things in the shop, but keep your eyes open, and ask questions, make notes, and we will talk it over at the end of the week. If you see room for improvement, just tell me where, and don't spare my feelings in the least. Let me know when to expect you.
>
> (Signed) BOB".

Being in a position at that time to take a vacation, I did as suggested, and trusting I may be pardoned for my apparent egotism in describing the conditions found there, and suggesting to readers who are desirous of making improvements in their own shops to arrange for a similar exchange of visits with friends in the same line of work. Just imagine on your visit that you are a highly paid expert procured to make a report of conditions as they appear to you, not sparing your friend's feelings at all, and as these reports need not be seen by others than yourselves, they can do you no harm in the estimation of your employers, and the experience will be of great value to you both.

A First Impression.

My first impression of the shop in question was that his estimate of conditions was correct. His speeds and feeds were as described, his men above the average in ability and willingness, the machinery well kept up, and apparently everything possible was being done; but, continuing the investigation, it was noticed when a belt broke, the operator repaired it himself, wire lacing being kept in the tool-room for the purpose. The practice resulted in a general run-down condition of the belts, each man having his own idea of what was the proper way to repair a belt, and apparently having his own opinion of the proper time it should take to lace a belt. Some very poor specimens of belt lacing were found throughout the plant.

*From a paper read before the Central Railway and Engineering Club of Canada, March 24, 1914.

**Foreman, G. T. Ry. Shops, Battle Creek, Mich.

One particular belt took eighteen minutes to get into service again.

A special belt-repair man can repair a 4-inch belt in less than four minutes, and I would recommend that a special man be appointed for this work who would care for, lace, and watch all belting, working during the noon hours inspecting belts overhead, and not waiting until they break before being repaired. This man would also inspect all split pulleys and counters during cessation, see that there are no indications of nuts, etc., becoming loose, dividing the shop into sections and going over each one in its turn, dressing the overhead belts with a good reliable dressing when found necessary.

A sticky substance should never under any circumstances be placed on a belt, but a dressing that goes into the belt, and put on both sides so that it will lubricate the fibres more quickly. Place in his hands some belt literature and see that he is intelligent enough to understand it by questioning him occasionally on the subject dealt with, and also see that he **knows** just what every foot of each size belting **is worth.** When he knows that a piece of 3-inch belting 3 inches long costs ten cents, his efficiency will be much greater than before he was so instructed.

It has been stated on reliable authority that it requires fifty per cent. more horse-power to operate a plant or shop equipment of tight belts than it does when they are in good condition and running slack. In shops where belting receives but little attention, the upkeep of countershafts, motor and other bearings, machinery, etc., is a matter not to be treated lightly.

High-Speed Steel.

While plenty of high-speed tools were in use throughout the shop, no high-speed drills were being used for the reason that they had such a large supply of carbon drills on hand. I advised procuring a 1-inch high-speed drill of a certain make, and that we would make a demonstration next day, which we did with the following results:

The best results with the carbon drill were obtained at a speed of 35 feet peripheral speed per minute, and feed 0.018 per revolution. The drills required grinding every ten holes. With the high-speed drill on the same class of work, we ran 90 feet per minute, feed 0.0250, and drilled 53 holes without grinding. On reducing feed to 0.018 several hundred holes were drilled without changing drills.

Lathe Work on Drill Presses.

Work was being performed on lathes with boring bars and threading tools by high-priced labor that could have been done equally as well and at much less cost, and in some cases in one-half the time, on drill presses by the use of special cutters and taps, the only changes necessary being altering the patterns so that instead of coring the holes almost the proper size which resulted frequently in the lathe hand being obliged to cut on the scale, they were left solid, the high speed drills and special cutters making much better time cutting from the solid than the lathe hand could possibly do by his methods. This condition seems to exist wherever I have had occasion to visit machine shops, and is well worthy of consideration.

Non-productive Periods of Machines.

When a change of jobs was to be made on the planers and boring mills particularly, much loss of time resulted in the operator either waiting for the traveling crane which was usually working elsewhere when wanted, or if at hand, the operator alone unloading or reloading his machine, cleaning cuttings out of bolt slots, bolting down and setting the new job himself, when a sufficient amount of help should have been available to do the necessary unskilled part of the work, thereby getting the full benefit of a skilled man's services with the least possible amount of delay. A mechanic's pay is only earned while doing work requiring a mechanic's skill.

This feature alone, of neglecting to obtain the most of a skilled man's time by allowing him to perform much labor that should be performed by helpers, is a most common form of shop inefficiency, and the importance of it was easily appreciated when the number of hours lost by machines and mechanics while changing jobs was pointed out. It is the idle hours of the machines, the non-productive minutes of each, which soon reach an appalling amount, if not carefully watched. Each machine depending on the traveling crane should be equipped with an individual crane and hoist, either electric, pneumatic or differential chain. These cranes are of so simple a form that they can be designed and built in an ordinary machine shop, and will pay for themselves in a short time.

When we consider that, if the traveling crane had but two machines to serve, there would arise occasions when one machine would be obliged to wait while the other was being attended to, then how much more delay occurs when forty or more are to be served. The lack of means, independent of the traveling crane for loading and unloading machines, is another all too common and neglected form of shop inefficiency.

Tool Grinding.

Each man was doing his own tool-grinding, the reason being to keep down discontent through having some dub do the grinding for good machinists. Just here, some will take issue and say he should have put in a tool grinding system if he thought well of it, whether the men liked it or not, that he was running the shop, etc. It must, however, be borne in mind that the business was paying well. His employers were not complaining on that score, but were well pleased with the results. Under the circumstances, having surrounded himself with a number of excellent mechanics, can we blame him for not wishing to deliberately create discontent?

As many of the men were on special work, each one having his own idea regarding the best form and shape of tools most suited to produce the best results, we decided, instead of installing all at once a general tool grinding system, to have a pattern maker construct exact models in wood of each kind of tool that had proved most satisfactory, consulting with the men themselves who had developed them as to details. This immediately got them interested as their ability was thus recognized.

The tool-smith then forged some of each shape, and a special man was appointed to grind them to the correct forms and keep them in the tool room, to be taken out as wanted, being called for by number, which was shown on framed blue-prints having reference to the class of work they were for. The men, seeing that these were their own design of tools that were being kept up, and soon learning that operating a machine was easier work than grinding rough forged tools, fell in with the idea, and I have since learned that the system now extends over the whole shop, having the hearty support of all. This, accomplished in a few months with the co-operation of all, would have created discord and other undesirable conditions, had it been attempted all at once.

Oil Distribution.

Considerable loss of time was noted, owing to each man going to the store room for small squirt cans of oil when required, occasionally some six or eight standing at the wicket at one time. This was another instance of the skilled man doing an unskilled man's work. One of the laborers was given charge of the oil distribution each morning going the round of the shop with a large can and filling all small cans that were left in a given place on machine or bench. No conversation with the men was necessary, and he now serves those of one hundred and fifty users who require it, in three-quarters of an hour each day. He is also supplied with a record book, so that a tab is kept on the amount of oil being used daily, and should the amount appear to be too large at times, an inquiry can be made at once.

We will now close with Bob's shop, as I am not going to say what the result of correcting the inefficiencies we

found was in actual output, but no overtime was worked, only one machine was purchased, and the men were not chased any harder; while locating these inefficiencies was done in such a manner, that instead of the men being led to believe they were going to be shown up, instructed how to run their machines or made to work harder, they were induced to co-operate; most of them taking pride in offering suggestions with a view to increasing the efficiency of the shop, which spirit, I am told, still continues in evidence.

Pneumatic Tools.

The care of pneumatic motors is often neglected to the extent of amounting to a very glaring inefficiency, and to quote Mr. Kingman's remarks in "Ideal Power" who says, that after his locomotive has run 150 miles, a trained engineer proceeds to feel all the rod connections, see that they have had oil, see that all nuts and bolts are perfectly tight, etc., although the locomotive in that time has only made about 30,000 revolutions. Now, a pneumatic drill is some machine, when compared to a ponderous locomotive, and, in the hands of the most inexperienced help will, when used on drilling staybolt holes in this big locomotive's boiler, exceed 1,000,000 revolutions in a day of ten hours. When a locomotive makes a million turns it would have run 3,300 miles, and spent about two weeks doing it, and about half the time in the round-house receiving expert care and attention. The pneumatic drill is as fine an engine as any other type, and why not give it a little of the care that railroads are expected to give their locomotives. It would amply repay us in service.

I have seen many of the varieties of care these tools receive, thrown from the front end of a locomotive on to the floor, hammered to release the drills, run without lubricant of any kind for days at a time; this treatment mostly occurring when they are placed in the hands of unskilled labor, as the nature of the work these little engines can accomplish is such that the most unskilled employees can handle them successfully.

We must face these conditions, and I would suggest that the best way to overcome the misuse of these tools is to have the operator go into the tool room when a motor is being taken apart, and receive instructions as to the need of frequent oiling, and be shown the light construction of the cylinder walls, explaining that they were purposely made light for their welfare, so that they would not have the heavy weight to constantly handle, were they constructed so as to withstand rough usage. They should also be shown, while the cover is removed, the speed the inner works revolve at.

I have demonstrated, to my own satisfaction at least, that they will then have a much greater regard for these wonderful little engines, and the repairs found necessary will soon be those only due to regular wear and tear, which should be performed regularly each week; the motor being examined, adjusted and oiled, even if no repairs are necessary.

The Safety Movement.

The safety movement is now becoming nation-wide, and is recognized as an important factor of shop efficiency, but until quite recently, I think there has been no more neglected feature of shop efficiency than the consideration of such rules of safety as would insure the minimum amount of time lost through accidents.

I well remember the words of one superintendent I worked for in Canada who, in addressing the employees after an unusual frequency of casualties occurring in the works, said: "While you men have a perfect right to injure yourselves if you wish, you have no right to impair the efficiency of these works in doing so, for it is not only the loss attendant upon your own personal injury with your enforced absence from your work, but one serious accident in a plant affects the efficiency of the whole organization." While this seems to be somewhat of a heartless argument to advance as a reason for not getting hurt, still we must admit that the contention is correct.

The New Man.

Another important shop problem affecting its efficiency, and the last one I will deal with, is that of the new man. It is fair to assume that you need the new man quite as much as he needs the job, but too often he is discouraged the first morning by the manner in which he is introduced to his new job, which frequently is about as follows:—

A small boy from the office escorts him through many devious ways, past whirring machinery, among strange and perhaps unfriendly faces to a busy foreman, with a note instructing him to start this man as a lathe hand, we will say. This foreman, who perhaps is, unintentionally, out of sorts that morning, gives him a cold look and takes him to a lathe, shows him the material to be worked up, hands him a blue print, telling him to whale in and that the job is in a hurry. This sort of an introduction is enough to discourage the average man at the start, and do not be surprised if your new man will within a few hours come up, tap you on the shoulder, and ask you for his time, especially if work happens to be plentiful elsewhere, in which case you need his services all the more yourself.

Now, I hold that it is just as essential that a foreman be competent to fulfil efficiently that part of his duty which calls for getting the new man properly started as in getting the new machine properly installed, and quite frequently it is just as necessary. The new man should be received cordially, questioned in a friendly manner, to ascertain what he is most accustomed to work at, and learn what class of work he considers himself most competent to perform. Make a note of this information for future reference, as it will be of value when certain vacancies later occur, then explain to him just how the work should be handled. Should he be placed on a class of work for which it has been practical to make an operation sheet, hand him one. From a series of motion studies taken previously, each operation is numbered, shapes of tools decided upon as being the best so far discovered, and feeds and speeds that have been found the most effective printed plainly.

The man, on starting, should be told that the sheets describe the best method that so far has been evolved for performing that work, and that if, after acquainting himself with it thoroughly, he can improve upon it in any way by making any change, that you will be pleased to consider it, advising him that you are looking for the class of men who can improve upon existing methods. You thus succeed, as it were, in challenging the new man to do even better than his predecessor, and have made him feel that he has an opportunity. He does not have to approach a new and strange job with nothing to guide him. His standard practice card tells him just how his predecessor went about it, how long he took to arrange his tools or fasten his chuck, which part to machine first and why, styles of tools he used and total time it took to complete the job. Should he find himself falling behind he can, without asking questions, ascertain just where he is losing.

The time of these operations should not be the best that is possible to obtain under the most exceptionally favorable conditions, but should be based on the time taken to do a number, to which has been added the necessary time taken for grinding tools and personal needs. Make the sheet a fair and straightforward one, and your new men will soon get to appreciate the value of it to themselves as well as to the efficiency of your shop.

Securing a Motion Study.

I would call attention to the steps taken in securing a motion study which has been extensively adopted.

1—Make time study of motions as at present.

2—From the time study ascertain the proportion of idle time and amount of productive to non-productive motions.

3—Determine present motions that are unnecessary.

4—Study each motion separately and its relation to the preceding and succeeding one to determine the easiest and quickest manner in which each may be performed.

5—Group motions into unit operations.

6—Assemble unit operations in proper sequence.

7—Re-establish total time for one complete cycle.

From this data you may then construct your shop standard practice cards, making the allowances I have already spoken of. Many operation sheets are treated with deserved ridicule by the men, owing to the assumption that a machine can be operated all day long at the same rate, that one single piece can be machined under the most favorable conditions of newly ground tools, and no allowance made for distorted, hard or bad castings.

While looking at this standard practice card, attention is called to the advantage of the extended use of various size chucks fastened to the regular tables of boring mills over the method of attempting to do all classes of work on the one large chuck or four independent jaws usually furnished with these machines.

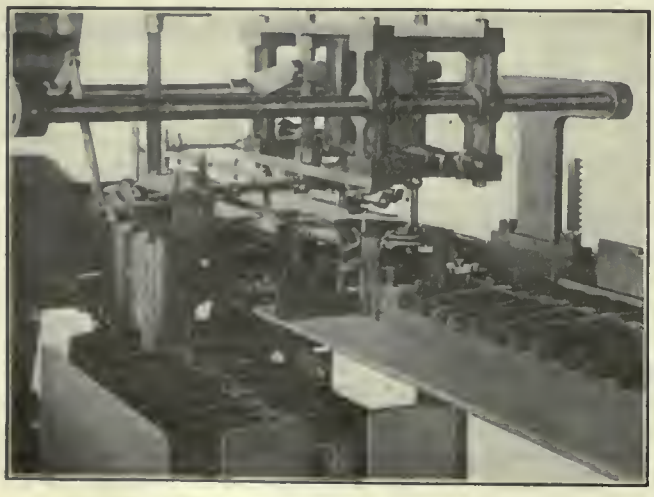
I have left untouched many forms of shop efficiency that could profitably be discussed also, but, if I have succeeded in showing that, after all, shop efficiency is not so much a matter of modern machinery, not so much strict discipline, and not so much complex organization, although these are all very desirable, as the thorough understanding of men, I shall feel repaid for my labor.

The Mechanical Banding of Box Packed Cigars

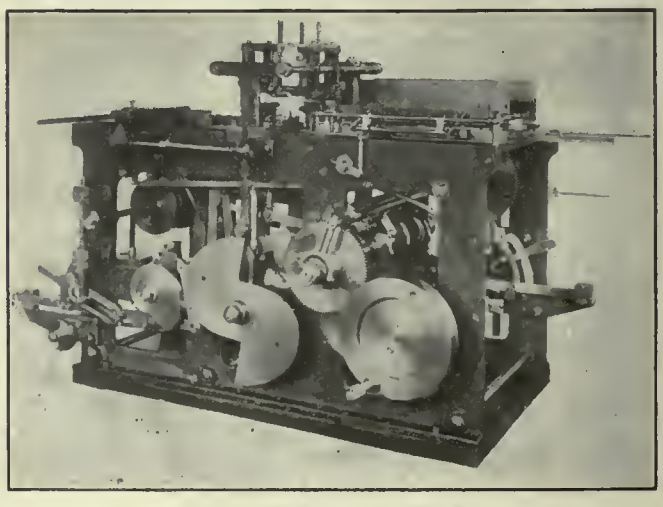
By J. E. Pruden

Cigar smoking has long since ceased to be a luxury, except perhaps in the matter of quality. In any case most all of us have often been chagrined to find with the removal of the band that the wrapping has been injured. The accompanying article deals with an equipment to not only prevent such a trouble, but is also more rapid than hand banding.

WHEN a man tears the band off his cigar and finds that with it he has flaked off a piece of the wrapper he is apt to vent his exasperation in no mild terms against the whole system of pasting paper seals about cigars. Yet the very next cigar he buys will be a banded one, for he has no confidence in brands that do not bear a mark of identification. As a matter of fact it is not the band that he objects to but the careless way in which so many of them are applied. Unless he knows something about the cigar business he is inclined to blame the manufacturer for employing "cheap help" and antiquated machinery that cannot put on a band without gumming it fast to the cigar. No doubt, it will surprise him to learn that all packed cigars, that is, the product packed in boxes, have to be banded by hand at an expense that is estimated at over two million dollars per annum.



BANDING MECHANISM IN THE ACT OF REVERSING.



REAR VIEW OF MACHINE.

Difficulties of Machine Banding.

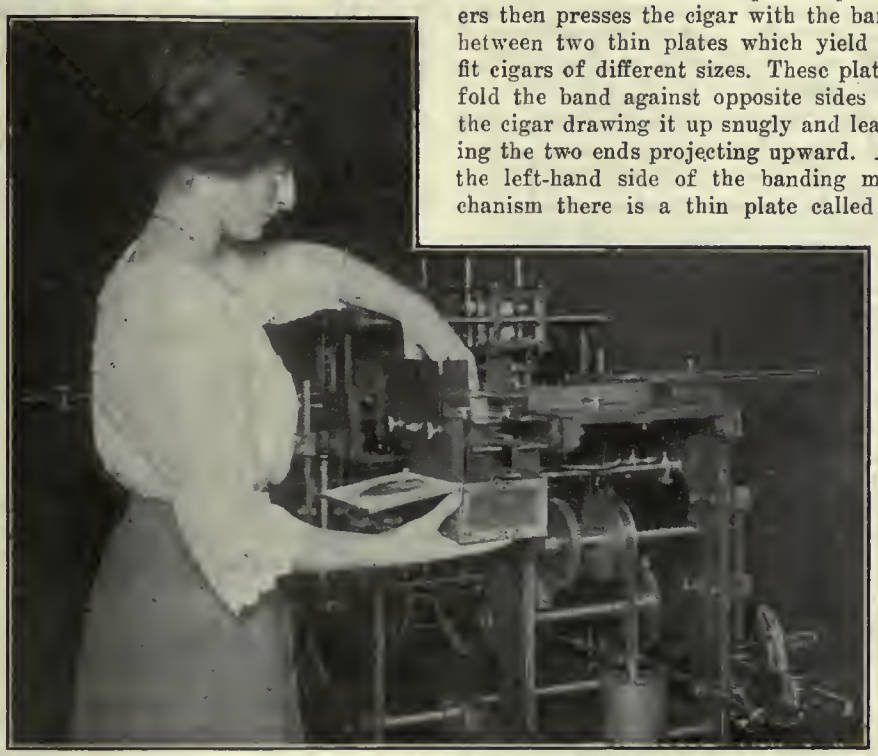
Manufacturers will explain to him that it is impossible to band cigars by machine for the following reasons: Cigars that are packed in boxes must fill the box tightly so that the customer may be satisfied that he is receiving full measure. The cigars are fitted into a box and placed under a press where they remain for several hours until they have been compressed sufficiently to permit of closing the lid upon them. It would not be a very difficult matter to band these cigars before they are placed in the box for then they are of uniform size, particularly if made by machine, but in the process of compressing, the paper bands cannot be made to contract with the cigars and so would be too large for the cigars. They would also be badly creased and generally dilapidated when the box was removed from the press.

It is therefore evident that the banding must be done after the packing; but then the cigars are of irregular form. No longer are they round, but flattened in many sides by their contact with the other cigars in the box and otherwise twisted and bent out of their former shape, while some of them have been compressed more than others. It is because of this irregular form that it is difficult to devise a machine that will band the packed cigars. Added to this difficulty is that of preserving the original order which the cigars occupy in the box otherwise when they are returned to the box they cannot be made to fit.

Machine Banding Superior.

Nevertheless, despite all these difficulties a machine has been developed which will perform the work of banding packed cigars, meeting all the requirements of the industry and turning out a product far superior to that obtained by hand. This machine was devised by a mechanical engineer who was thoroughly familiar with the conditions that had to be met. He was aware that a cigar is a very delicate article of manufacture and must be handled with the utmost care lest the thin tobacco wrapper be injured.

With this in mind the mechanism was adapted to pick up the cigars on rubber stems connected with a suction pump so that the cigars were held not by mechanical means but by atmospheric pressure. The fingers for applying the band snugly to the cigar do not touch the wrapper but press upon the paper only. Hence, although the band is drawn very snugly about the cigar there is not the slightest possibility of tearing the wrapper.



PACKING PROCESS AFTER BANDING.

It is the practice in hand-banding to invert the cigar box upon a table, keeping the cigars in the same relative relation to each other as they were in the box. The bottom row of the box is now the top row, so the operator start banding with the bottom row, replacing each cigar after the operation in the precise position it formerly occupied.

Machine Banding Process.

The same process is employed in the machine. The cigars are removed from the box by inverting it upon a tray. This tray is placed in the machine and the cigars are removed from it one row at time; but instead of removing the top row first, the bottom row of the tray passes first into the machine, for the banded product is discharged by the machine not directly into the box, but into a second tray. The row of cigars is fed to the banding position with a step by step movement, the length of each step being equal to the average width of the cigars. As the cigars are fed forward they are picked up one by one by a suction device which draws them away from the rest of the row and carries them over to a pair of rubber stems upon which they are individually supported and transferred to the banding mechanism.

The cigar bands are held in a bracket directly above the banding point. Immediately before the arrival of the cigar a suction tube rises and removes a band from the bottom of the pile, drawing it down to such a position that the cigar will be centered over it. A pair of plungers then presses the cigar with the band between two thin plates which yield to fit cigars of different sizes. These plates fold the band against opposite sides of the cigar drawing it up snugly and leaving the two ends projecting upward. At the left-hand side of the banding mechanism there is a thin plate called a "tucker" which moves over the cigar, tucking the inner end of the band down in place and holding it there for a moment while the outer end of the band is being folded down by a roller, then receding before the advance of the roller. While the roller is pushing the overlapping end down, it presses it into contact with a gumming plate located just above the tucker plate. The gumming plate is connected by a flexible tube having a cylinder filled with gum and at the proper instant a plunger in this cylinder is depressed one ten-thousandth of an inch causing a minute quantity of gum to be forced out upon the plate. This is wiped off on the outer end of the band immediately before it is pressed down by the roller. The latter withdraws at once and the cigar is picked up on a second pair of rubber suction stems and carried over to a delivery table.

The process of banding each cigar occupies but a second of time. When the entire row has been banded a second row is pushed from the tray into the machine while the banded row is ejected from the delivery table into the discharge tray. The latter immediately moves down a trifle so as to receive the next row of banded cigars above the first. When the entire box-full has been banded, the cigars will be found in the delivery tray all neatly banded and in precisely the same order as they occupied in the first tray. The box is now inverted and fitted over the end wall of the tray, after which tray and box are both turned over and the cigars are pushed out of the tray into the box by means of a bar.

Caring For Packing Methods.

If this were all that the machine did it would mark a decided advance in the industry, but it has been carefully devised to meet all the special requirements. For instance, cigars are packed in rows of ten and ten or of twelve and thirteen. In order to adjust the machine for these variations, the cam shaft that governs the feed of the rows into and out of the machine is driven by a ratchet mechanism. It carries two ratchet wheels,one of which is formed with 20 teeth evenly spaced, while the other has 13 teeth on one half of the wheel and only 12 on the other. When the latter wheel is thrown into operation, the machine will band 12 cigars before the pusher slides operate, then 13 cigars, then 12 and so on. Again if the other ratchet wheel be in action, the pusher will always operate at the end of ten operations of the banding mechanism.

Some boxes are packed with alternate rows reversed end for end. When banding a box such as this, the bands must also be reversed for alternate rows. The machine is arranged to do this automatically. After a row of cigars has been banded in the normal way, a spiral cam comes into play which causes the banding mechanism to turn through an angle of 180 degrees as each band is picked off the pile, returning the parts to noraml position the instant the cigar has been handed.

Boxes of different makers are apt to vary in size, but in order to make the machine universally applicable, a scale is provided by which measurement of the length and depth of the box may be taken. Corresponding adjustments are then made, one of which controls the feeding of the cigars toward the banding mechanism, while the other controls the drop of the delivery tray after each row has been delivered to it. A ratchet wheel is provided which has 100 teeth, and a ratchet mechanism may be set to move the wheel to a space of one, two or four at a time depending upon whether there are to be a hundred, fifty or twenty-five cigars to the box.

The machine requires but a single operator and its capacity is 3,600 cigars per hour, or ten times as many as the average girl can band by hand. Out of an annual output of eight billion cigars there are two billion put on the market without bands, merely because hand-banding is too expensive. These could all be banded profitably by machine.

PRODUCTION METHODS AND DEVICES

A Department for the Interchange and Distribution of Shop and Office Data and Ideas Evolved from Actual Practical Application and Experience

TURRET LATHE AND VERTICAL BORING MILL PRACTICE.*

By Albert A. Dowd.

HUBS and flanges for automobile work present certain problems in machining which are solved by various manufacturers in ways differing considerably on account of the difference in production required. The flanges are not specially difficult to machine, but the hubs require careful handling, and the tooling for these parts must also be carefully considered, for in many cases inserted bearings are used at each end, and it is essential that these should line perfectly one with the other in order to avoid any possibility of "cramp" in the bearings. Hubs are somewhat varied in design according to the class of car on which they are to be used, but the important points in the machining operations have a strong family resemblance. The flanges do not differ greatly in design. As there are at least four each of hubs and flanges used in each car, to say nothing of extra parts required for repairs and replacements, it is evident that the production is a matter of some moment and that both rapidity and accuracy must be carefully considered in the machining operations.

Means of handling have been developed and improved so that very accurate

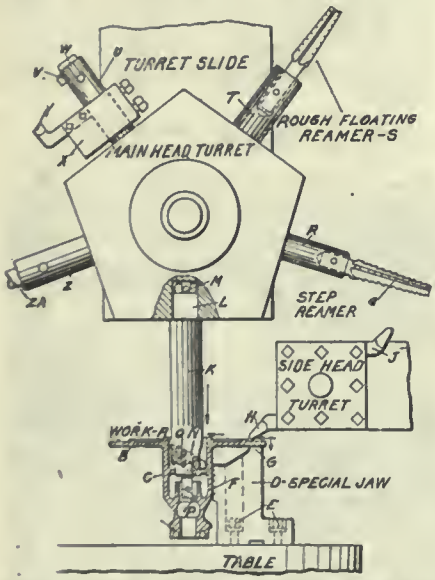


FIG. 1. FIRST SETTING OF STEEL REAR HUB, A.

and rapid production methods are now in vogue in nearly all factories where the yearly output warrants the expenditure. When ball or roller bearings are used, the bearing seats must not only be machined within limits of .00025 to .0005, but they must also be in alignment. It is obvious, therefore, that very accurate tooling and holding devices are necessary in order to produce the desired results.

In the machining of such work as hubs and flanges, considerable trouble may be experienced when facing the thin portion of the flange unless the fixture or holding devices are arranged so that good support will be given and "chatter" thereby avoided. The horizontal turret lathe is frequently used for work of this character, and special holding devices, expanding arbors, and special tooling give rapid and accurate results.

The vertical turret lathe is a machine tool which is also strikingly well adapted to the work, and the examples here given represent holding devices and tooling for this machine.

Machining a Rear Hub on the Vertical Turret Lathe.

The first setting of the steel rear hub A on the vertical turret lathe is shown in Fig. 1. A set of special jaws D are fastened to the sub-jaw in the table chuck by the screws E. The hub C is gripped by the portion F and the flange B is supported by the upper part of the jaw G. Vertical location is also assured by these points. The tooling is as follows:—The boring bar K is of .040 carbon steel and fits the turret hole at L, being driven by the pin M in the usual manner. Three cutters are used in the bar and are shown at N, O and P. The first two of these are fitted with backing-up screws for adjustment and are used to rough-bore the bearing seat and the clearance hole respectively. The lower tool P is used to break the scale in the taper hole and generate a true hole for the other taper tools.

All tools used in this bar are of high speed steel. A high speed steel step reamer Q is fastened into the shank R, which is of .040 carbon steel and obviously fits the turret hole. The reamer S shown in the upper turret face is also of high speed steel, with a left-hand thread cut along the flutes in order to break the chip. This reamer is of the floating type and is held and driven by the holder T. The finish boring and reaming bar U is furnished with a slip cutter V and two flat floating reamers W, thus ensuring great accuracy in the finished hole. A special tool holder X is fitted to the shank of the boring bar and contains a bent sizing tool Y for the shoulder. A finish floating reamer ZA is held in the holder Z and is much the same as the reamer S, except that no grooves are cut in the flute. The two roughing and finishing tools respectively

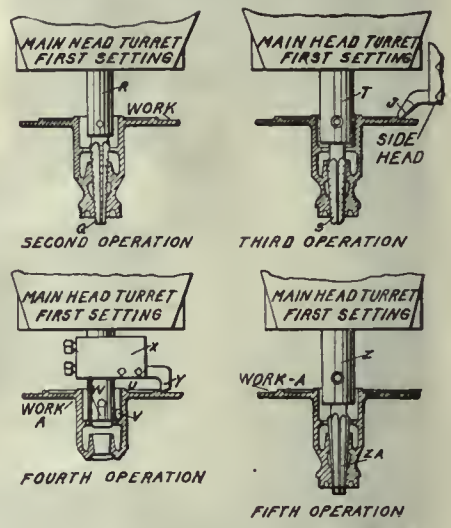

FIG. 2. SECOND OPERATION—SECOND SETTING.

are of high speed steel and are securely held in the side head turret.

Sequence of Operations.

First operation:—The tools shown in Figure 1 in the cutting position are those used for the first operation, and it will be noted that during the progress of the boring the side head tool H faces the end of the hub and rough faces the flange as far as the shoulder, after which it trues up the outside of the flange. The boring bar and side head turret tool are working simultaneously during this operation. An important feature of this tooling is the generating of the rough trued hole in the tapered portion by the tool P, for unless something of this kind is done, any tools which follow will have a tendency to be thrown out of alignment on account of the inequalities in the tapered core. A method of this kind provides a true hole for the tapered reamers to start in, and the natural tendency is to follow it, so that final results are much more accurate than would be the case if tools were started in the rough cored hole.

Second operation:—Fig. 2 shows the second operation on the piece, which consists of roughing out the tapered portion with the step reamer Q. The action of this tool is such that it leaves the inside of the taper in the form of a series of steps and breaks the chips up

*First of a series.

into small pieces so that they are not troublesome. Easy cutting is also a feature of this type of tool, and subsequent operations on the same surface are also assisted. The side head is idle at this time.

Third operation:—Another taper reamer S is now used to take out nearly all the remaining stock in the tapered hole, leaving a very little for the finishing reamer. This reamer is ground to the correct taper, but has a left-hand threaded groove, about 4 pitch, cut along the flutes in order to break up the chip and make cutting easier. While this reamer is working in the hole the side head tool J finishes the flange, hub and shoulder, leaving a few thousandths at the latter point for the final sizing.

Fourth operation:—This consists of finish boring the bearing seat with the tool V and reaming the same with two flat floating reamers W; both the boring tool and the two reamers are of the slip variety and may be readily removed by the aid of the fingers alone. It is obvious that the reamers are not placed in the slot until after the boring tool has been removed. The bent tool Y is set at the correct distance from the center of the bar to properly size the shoulder on the work. The side head is idle during this operation. Attention is called to the fact that the method of sizing the shoulder gives very accurate results because the main head is in its fixed central position and the required diameter is therefore assured.

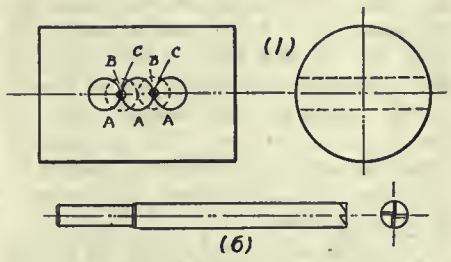
Fifth operation:—The final operation is that of reaming the hole with the reamer ZA. This reamer may or may not have straight flutes depending on the angularity of the hole. If taper is very acute, it is sometimes well to make the spacing of the flutes unequal and to give an odd number of teeth to the reamer, in order to obviate any chance for chatter. It is also sometimes advisable in cases of this kind to mill the flutes left hand at an angle of from five to seven degrees in order to avoid a **pulling-in** tendency. This operation completes the first setting of the work.

Between the first and second settings on the vertical turret lathe, a drill jig is used for the flange holes, but as this jig may be of a comparatively simple nature, no description seems necessary at this time.

SIMPLE FIXTURE FOR DRILLING OUT A BROACH.

By James E. Cooley.

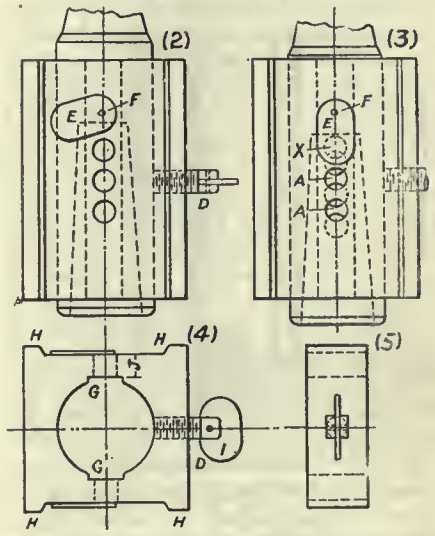
THE usual method for making a broach in a spindle, shaft, collet or boring-bar, is to drill a number of holes on a line as close together as possible, as shown in the sketch at A, Fig. 1, and then chisel out the remaining stock, as at B. Where no jig is used for drilling the holes they have to be layed out. As the work to be drilled has to be stright to run true before the broach is finished, it does not help it any to pound on it to chisel away the stock at B. A better way is to plug up the drilled holes, A, with similar material, and then drill new holes at B, which will cut the stock away. The remaining parts of the plugs



FIGS. 1 AND 6. BROACH DRILLING FIXTURE.

can then be forced out. If holes are first drilled in a short depth at the points C C with a small drill, they will guide the larger drill to run central. The jigs commonly used for drilling out a broach are similar to that shown by Figs. 2, 3 and 4. In these particular sketches a number of improvements are suggested and described in the course of this article.

These jigs are made from square-stock, planed up and hardened. Ordinarily three holes are sufficient to complete the work of drilling out a broach. The work is placed in the jig and fastened in by the screw D. When drilling into work having a taper-hole, one side only



FIGS. 2-5. BROACH DRILLING FIXTURE.

at a time is drilled, then the jig is turned over and the other side is drilled. This is necessary, as the drill will glance off on the taper if put clear through from one side of the jig. When the three holes have been drilled, the screw D is unfastened and the jig is moved along till the undrilled portion of the broach is half-way between the holes A A, Fig. 3. A four-toothed butt-mill is used in place of a drill when cutting away this stock, as a drill will break if run between two holes. A butt-mill is shown in Fig. 6, and is made from drill-rod and hardened, the teeth being filed in by hand.

When preparing to use the butt-mill, the third hole in the jig as X, Fig. 3, should be covered up as there is no stock there to be cut away and there is danger of running the tool into it. The usual practice is to stop up this hole with a round wood-peg or dowel-pin, but as this sometimes gets mislaid, there is danger in not replacing it when needed. A suggestion to prevent using this hole by mistake is shown in the caps E, that are fastened to the jig by the pins F. Figs. 2 and 3 shows the cap in its respective positions. The one in Fig. 2 is swung back out of the way in order to drill the third hole, and in Fig. 3 it is pushed forward over the third hole to prevent running the butt-mill down into it.

Another suggestion shown is the grooves at G, Fig. 4, splined through the length of the jig on both sides of the hole. The purpose of these is to allow the drilled work to be moved along or taken out easily from the jig, as the top burrs made by the drill cause the work to stick. The four projections as at H is another improvement, as it allows the jig to set down flat when there may be chips under it. A square head set-screw is cheaper than a thumb-screw, but, since it requires lifting and handling a wrench each time to fasten and unfasten one, it is more economical to convert a square-head screw into a thumb-screw, as shown at I.

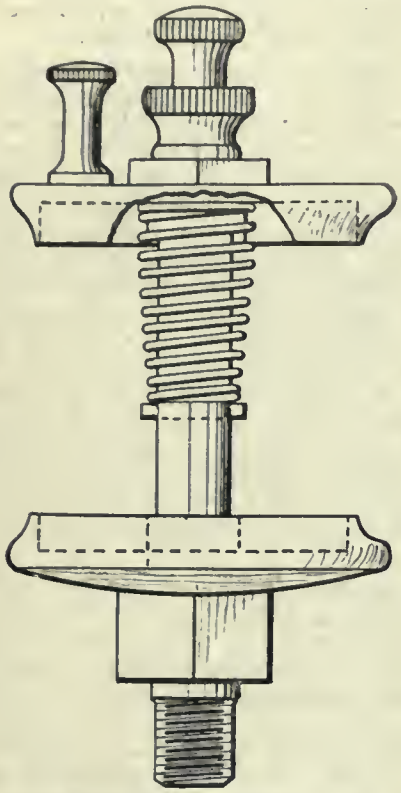
When the stock to be drilled is very long, such as a drill-press spindle, etc., it will require a support of some kind to hold it up on its outer end. A support for this purpose can be made up similar to that shown in Fig. 5, of the same size stock as the jig. When making a jig for drilling a broach, it is advisable to make the stock large enough, so that the space at J is at least ½ in. thick, in order to have a long bearing in the holes for the drill and butt-mill. Usually the thickness at J, on most jigs, is only ⅛ of an inch.

AN IMPROVED OIL CUP.

By F. A. Wright.

THE oil cup herewith illustrated is a standard patented article for oiling engine crank pins. It is arranged to supply the proper amount of oil to the bearing while the engine is running, and to shut off the supply when it is stopped. The one fault with the apparatus was forcibly brought to the attention of the writer upon several occasions.

When the glass was accidentally broken, the heavy brass cover became loose and unmanageable, and it was but a



AUTOMATIC CRANK PIN OILER.

short time before the complete apparatus became a wreck and had to be replaced. By drilling a small hole in the shank and placing the stop pin and spring, as shown, the repairs necessary were minimized. The spring furnished a strong and elastic support for the cover upon the glass being disabled, so that in case of breakage further damage was prevented and the renewal of the glass alone was required.

ANCHOR BOLT FOR CONCRETE.

By Alfred McCormack.

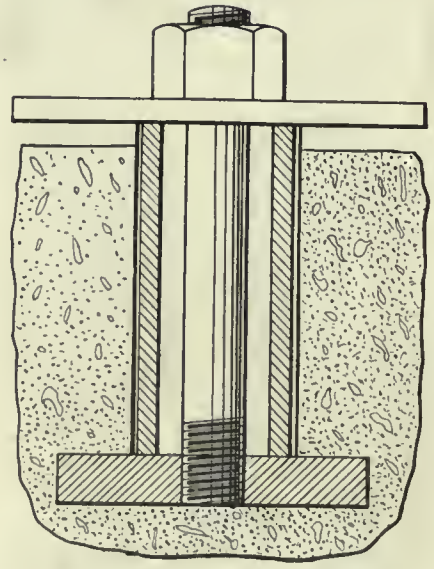
WITH the passing of the use of brick, stone and wood for the foundations of buildings and machinery and the substitution of concrete, there arises the necessity of devising new means of placing the holding-down bolts. Many different ways have been tried and adopted. The most natural, probably, is to simply bed the shank of the bolt solidly in the concrete. This has many disadvantages, most of which are known to the man who has to do the setting up of the machinery or superstructure.

The most convenient method which has been met with by the writer throughout a wide experience is shown in the accompanying cut. It consists of a central tie-rod fitted with a standard nut at the top and a special cast iron nut or tapped steel plate for the bottom. A piece of standard W.I. pipe large enough to leave a space as shown around the bolt is next clamped between the two nuts and outside of this again and fitting fairly closely across is a galvanized iron tube.

The bolts are hung in the templet in the usual way at the required elevation, all burrs having been first removed from the ends of the pipe, and the nuts are tightened up. After the concrete has been run in and has set, the templet can be removed, and the pipes are drawn out by means of holes drilled near the top for the purpose. The galvanized iron tube holds the bolt with plenty of clearance for adjustment of the machine or column.

The pipes may now be used as rollers for moving the machine into place and can afterwards be cut to suitable lengths, replaced and used to support the machine in the proper place while the grout is setting.

Some of the advantages of these anchor bolts are, that if the bolt be originally made too short or too long, they can easily be removed and made right without disturbing the machine. The millwright can easily satisfy himself that the bolts are gripping tightly and in the proper places. Then again, there is no danger of injury to the bolts by careless lowering of a heavy column upon them.

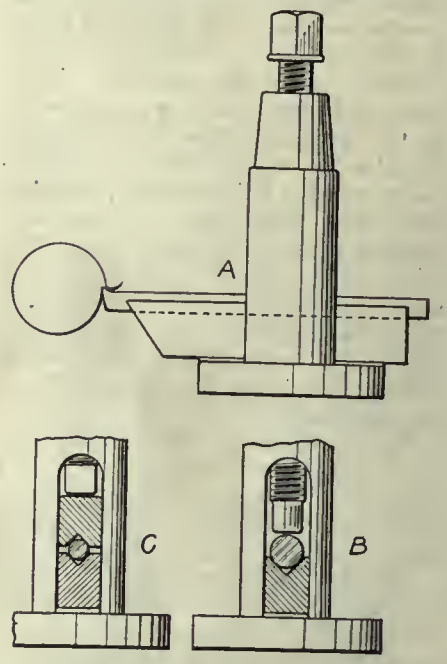


ANCHOR BOLT FOR CONCRETE.

TOOL HOLDER FOR LONG LENGTHS.

By N. G. Near.

IN the accompanying sketches is shown a very simple means for quickly clamping long lengths of self-hardening steel in the lathe tool post, and which the writer has not seen elsewhere than in a shop where he once worked. There is less waste of steel when long lengths such as this can be intelligently used and the



TOOL HOLDER FOR LONG LENGTHS.

tool post screw clamps the whole in a single operation.

In the figure, A shows the arrangement as applied to the regular square high-speed steel. The supporting block is tool steel and, in this case, has a square groove planed in its upper side to fit the size of bar used. At B is shown the same method applied to the larger sizes of round steel which will be found especially useful by tool makers in boring long holes. For small bars the arrangement shown at C has been found most successful.

The tools after being used up to lengths suitable for the regular patented holders are transferred to them and a great economy in tool steel has thus been effected. For small or inconvenient turning or boring this method has proved very flexible as it possesses the greatest degree of adjustment.

FORD MOTOR CO. SHUTS DOWN.

FOR the first time in its history, says a Detroit dispatch, the Ford Motor Co. on July 25 suspended operations for a period of ten days, and the entire force of employees, approximating 20,000 men, will be idle for that length of time. Officials of the company announced that the shut-down was for the purpose of taking an inventory.

When those at work during the light season laid down their tools on the previous evening they were informed by the heads of the various departments that their services would not be needed again until Monday, August 3.

THE COLLEGE GRADUATE—I.*

D. S. Mann.

WITH the close of the 1913-1914 session a month or two ago, another crop of college graduates has been put on the market by our progressive universitins and colleges to perchance transform the industries of the lond and to eradicate the evils thereof. The writer, while perhaps not as competent to discuss the advantages of a college education in the business world as many others, yet being a college graduate himself, and also employing college graduates, feels that he would like to register his views upon this important subject, these ideas being based upon practical as well as on theoretical college work.

Entrance on Practical Work.

Each year a larger number of students are turned out, and the problem of their absorption becomes more and more vital, both to the employer and to the college graduate himself. The student of to-day is the manager and superintendent of to-morrow and as such must be reckoned with. Most college graduates leave school with an exaggerated idea of the importance of their education and of their intrinsic value to large corporations and manufacturing concerns, but when, at the completion of their course, they are finally hired and put to work under a three-dollar-a-day gang boss, some of their ideals are rudely shattered. They find that practical experience is placed far above a mere college education, and they are called upon to endure the gibes and sneers of their fellow workmen, who never fail to take advantage of their ignorance and unfamiliarity with the work in hand.

However, the man who is downed by such small matters as these is not worthy of the name. The college man who has taken advantage of every hour put in at his work, who goes into a shop with the determination to get ahead, to keep his mouth shut when he does not know, who keeps his eyes open, who grasps every opportunity to add to his theoretical knowledge with the practical work before him, will soon pass the man who has not had his kind of education. In other words, of two men with the same amount of brains and calibre in every respect, and with the same determination, the college man should win out, for he has the knowledge to apply, to enlarge and to improve every part of the work in the factory or vocation with which he comes in contact; but this is only so when he brings with him good common sense and is willing to start at the bottom and depend upon his merit to get to the top, and not merely upon the fact that he has a college education.

Colleges Lack Touch With Actual Labor.

The writer has always felt that there was something lacking in the college education as found in the colleges themselves. While colleges are not expected to turn out practical men, yet they should turn out men who are fit to take their places in the world, at least as well as those who have had less favorable opportunities. Of course, some occupations demand preliminary training and the employee must first familiarize himself with certain details and routine regardless of his previous experience or education. However, that is no reason why a man should be turned out after four years college training with hardly any of the rudiments so necessary in the world of labor. We usually find the majority of technical graduates located in drafting rooms, and for some reason a high percentage of this majority remain there; whether it is because as draftsmen their work is clean and they are enabled to leave the shop with white collar and cuffs or because they have not the ambition to pry further into the details of business than that entailed in mere planning rather than in execution.

The writer was extremely fortunate in having it impressed upon him during his college career by a certain professor who was a consulting engineer, and who certainly possessed a thoroughly practical as well as theoretical education that it was necessary for a man to imbibe the spirit of the times and that this could only be done by actual association. To this end a great portion of the time was devoted to making visits to manufacturing plants and branch houses, power plants and every other source whereby information could be gained along the lines of study followed. In the mechanical drawing classes we were compelled to laboriously draw in the curves of all the teeth of a gear, for what reason I have never been able to divine, unless it was that too many drawings might throw too much work upon the professors who then were devoting most of their spare moments in the daytime to playing billiards, and at night to preparing lessons for a correspondence school.

Upon obtaining blueprints from firms that had use for such, the discovery was made that three dotted circles around the circumference indicated the presence of gear teeth, while all the data necessary for the production of these teeth was neatly summed up in a little note at the side giving the pitch, pitch diameter, and the outside diameter. The time consumed in producing the latter drawing was probably only about one-twentieth of the time taken up in the college drafting room on the much-drawn artistic, but hardly as useful one. Numerous instances such as this could be mentioned, but it is necessary? Is it any wonder that some of the draftsmen turned out each summer are glad to get at least two dollars per day for turning out artistic but impracticable work? Would it not be much more profitable for the student to be turning out drawings such as are in actual shop use, and if time permitted, to turn out a larger number and thus increase his working knowledge to that extent?

Ignorance of Shop Drawing Requirements.

In most cases, however, the student is hardly to be blamed, but rather to be pitied. A certain student, after graduation, considered that he was fortunate in getting into the drafting room of a large gas engine factory in which an instructor in mechanical drawing from one of our leading State Universities was to be employed for the summer. The opportunity of his career seemed now to be opened before him; here he would have the advantage of daily intercourse with an instructor and under his tutelage would surely make great strides along this line of work. The drawings produced that summer were almost without number, and drawing paper, tracing cloth and blueprint paper disappeared as if by magic. They sat on stools for ten long hours per day, but not once during that time did they visit the shop to see how those engines were being actually produced, or to determine whether jigs and tools were in use for the duplication of parts.

Many of the engines had been built merely from a single sketch and an explanation from the designer, and the majority of the dimensions had only been scaled off the original drawing. However, our friends, by carefully measuring from the rough surfaces of a

*First of a series.

single casting were able to get within a thirty-second of an inch; holes which had been laid out on the circumference of a circle were dimensioned from center lines; diameters of bosses were given as distances from the edge of a hole and various other liberties taken with the art of drawing. The professor in charge who was drawing $125 per month, was supposed to be well up on the subject, and, as far as the writer knows, his work was never checked. When the toolroom and the machine shop foremen came to use some of these drawings later, after the professor had left, the language used would hardly look well in print, while about five bushels of tracings were afterwards scrapped.

Train for Practical Work at Start.

Was this the fault of the instructor or the instructed? Neither, it seems, knew very much about the particular subject of gas engine design and hardly anything about machine shop work, or even the proper method of dimensioning drawings so that they might be useful for reference later on, yet this instructor was drawing a good salary for the very purpose of teaching the proper method of making working drawings. College mechanical drawing courses would be very much more useful if the men at the head were forced to have a few years' practice in a machine shop instead of only three months in the college workshop. Since a man's college education is supposed to fit him for the activities of a business life, why should not his training be such as to fit him for this work, rather than in many cases making him a laughing-stock and causing him to begin at the bottom and learn all over again. Of course, there is no doubt but that his training prepares him for much more rapid advancement than the man who has not had such training, but if it is possible to so train him that he is able to fit into active work at the start, why should this training be denied?

It is well understood that our colleges are not meant to turn out specialists, but to so prepare a man that he may be able to enter any particular line and, in a short time, adjust himself to his surroundings, and advance himself accordingly. However, it must not be forgotten that we live in a practical age and for this a man should be prepared. An instructor should be a man who has both practical and theoretical knowledge, so that he can appreciate the obstacles which are to be met in both directions and be able to train the student in such a manner as to avoid a goodly portion of them.

Do the work you are fitted to do. If you are a pumpkin-vine, do not try to become a morning-glory.

THE SUBURBAN MIGRATION OF INDUSTRIES.

By J. P. S.

THE continually changing conditions of life and progress are nowhere more in evidence than in the industrial field. On account of poor transportation facilities and inefficient means of power transmission the tendency has been to concentrate manufacturing activities and processes into as small space as possible. With this end in view and thoughtless of other consequences the great manufacturing institutions of ten or twenty years ago huddled themselves about the sources of power and the supply of materials, the result of this being the Manchesters, the Sheffields and the Pittsburghs of to-day. The unattractiveness and degrading conditions of all great centers have bevome bywords with us. It has been shown that, of men from the country who go to work in the factories of London, ninety per cent. die out in the third generation, while competent authorities allege that were it not for the continual addition of immigrants and their children, the population of the United States would scarcely hold its own, a condition also which can be directly and indirectly traced to the working and living environments of great manufacturing centers.

In marked contrast to this are seen the conditions developing throughout the industrial area of Ontario. The harnessing of sources of hydraulic power, the rapid perfection of means of power transmission and the increasing efficiency of the small motor are doing much towards bringing about such working conditions as we have long sought and considered feasible only in a residential sense. Our cities are endeavoring to provide the suburban advantages within their borders to as great an extent as possible and perhaps for the small manufacturers they are still the most suitable locations in which to carry on operations, in spite of the burden of high taxation.

Just as close confinement and crowded conditions are conducive to physical weakness and disease, so does the atmosphere of large manufacturing centers lead to social unrest, industrial discontent, friction and strife. In the same way that sunshine and fresh air are the enemies of microbes and parasites, freedom to move around and room to think for oneself are the most effective antagonists of the agitator and similar fraternity.

An investigation of a number of Canadian machine plants has shown few labor disputes in the suburban shops, and when the extra expense of city life is taken into account, the wage advantage is bound to be very much in favor of the suburban mechanic. If peace and contentment be considered as productive of economy and efficiency in manufacturing, then the natural location of the plant is away from congestion and contagion.

In contrast to the near past when our manufacturing institutions sprang up in certain locations like mushrooms round a dunghill, the industries of the immediate future will be found seeking the broader, healthier and more vigorous usefulness of the suburban life.

THE STATUS OF TECHNICAL SCHOOL EDUCATION.

By "Observer."

MUCH has been said through the press and otherwise concerning the inefficiency and narrow scope of technical schools in Canada, and the Province of Ontario in particular. From a general standpoint, criticism of this import is no doubt merited, but the Canadian who hears it should know also of a notable exception to this condition. The new central technical school at Toronto has reached a point in its construction where a somewhat comprehensive idea of its immense size and perfect completeness in detail can be obtained from a properly guided two hours' inspection.

The building of this great institution was made possible and its success is assured by the hearty co-operation of capital, labor and business men generally, in an effort to raise the standard of craft intelligence among our great body of mechanics and tradesmen. The criticisms of those who decry the money devoted to increasing the attractiveness, the completeness and the efficiency of this institution are best answered at its head.

Our Government spends millions in teaching Greek, Science and Higher Ethics to the few, while in the schools for the masses the necessity of attractive and inspiring surroundings has not heretofore been practically recognized. The youth who applies himself conscientiously and earnestly to attaining perfection in the mastering of a trade should feel himself on a par with him who devotes probably less time and effort to a profession or some social attainments, for the usefulness of the workingman to society is as important as that of the man higher in the social scale. The degree of usefulness or annoyance is proportional largely to the culture, the character and the ideals that the worker associates with his trade.

The effect of these tenets, continuously applied by an institution as great and influential as Toronto's new technical school will be, cannot but react upon the social status of the mechanic to raise him in the estimation of himself as well as of those who may now despise him and with whom he is periodically at variance.

Series of Practical Questions and Answers for Mechanics

Every care is being taken to include only pertinent practical questions, and give same direct, reliable answers. Catch questions will be avoided. Attention is drawn to the alternating course in arithmetic, a concurrent study of which is recommended with that of the Question and Answer Series.

RELATING TO SHAFTING.

THE calculation of the strength of shafting is met with at every turn of shop experience, yet few mechanics are even able to satisfy their own curiosity regarding results. There are many formulæ for the purpose, each one being largely a different means to a common end. The purpose of this article is to give a clear understanding of the fundamental formula as well as instruction in the use of a few of the popular ones.

The beam formula $\frac{M}{S} = \frac{I}{c}$ also applies to shafting. M is the greatest twisting moment and is equal to the force in pounds which lends to turn the shaft, multiplied by its distance from the center in inches. In a particular case this would be the belt pull multiplied by the radius of the pulley.

S is the stress per square inch in the material, which in the case of shafting is entirely that of shearing, and, in calculating the strength, the shearing strength must be used.

I is the moment of inertia, as in beams, but, instead of being taken about a line through the section, it is taken about a point in the center or center of gravity. This is called the **polar** moment of inertia and will be denoted by J. The polar moments of inertia for different kinds of shafts, such as square, round, hexagonal, etc., cannot be found in the regular handbooks, but can be found by adding together the moments of inertia taken about two axes at right angles to each other and passing through the center of gravity.

c is the distance from the center to the outer surface, and hence is the radius of the shaft. The formula, therefore,

becomes $\frac{M}{S} = \frac{J}{c}$.

Question.—What force acting at the circumference of a 4 ft. pulley will be sufficient to twist off a 3-inch shaft?

Answer.—Formula $\frac{M}{S} = \frac{J}{c}$ becomes $M = \frac{JS}{c}$, $M =$. The acting force P multiplied by its distance (r) from the center, and the formula becomes $Pr = \frac{JS}{c}$ or $P = \frac{JS}{cr}$.

$J = .0988d^4 = 7.938$. d = diameter.

S = shearing strength of steel = 50,000 lbs. per sq. in.

c = radius = 1.5 in. and r = 24 in., therefore

$$P = \frac{7.938 \times 50000}{1.5 \times 24} = 10{,}848.8 \text{ lbs} =$$

5.424 tons.

Question.—If a pulley be keyed to a 4-inch shaft, how long must a one-inch steel key be in order, that the shaft and the key be equally strong? Consider the shaft as unaffected by the key-way.

Answer.—Every inch of the key will stand a shearing load of 50,000 lbs. This will give a moment of 50,000 × 2 = 100,000 inch pounds.

From formula $\frac{M}{S} = \frac{J}{C}$, $M = \frac{JS}{c}$

$J = .098d^4 = 250.88$.

S = 50,000 lbs. per sq. in. and c = 2 in. M or moment necessary to shear the shaft is $M = \frac{25.088 \times 50000}{2} =$

627.200 inch pounds.

As each inch of key takes 100,000 inch pounds, the length of the key will be $\frac{627{,}200}{100{,}000} = 6.27$ inches.

Question.—A 10-inch shaft has a 4-inch hole bored through its center. What would be the size of a solid shaft to sustain the same twisting force?

Answer.—For a hollow shaft $J = .098(d^4 - d_1^4)$, where d = outside diameter and d_1 = diameter of hole.

For a 10-inch shaft, this becomes 947.9.

$$M = \frac{J \times S}{c} = \frac{954.9 \times 50000}{5} \quad \ldots (1)$$

For a solid shaft, $J = .098d^4$, and $c = \frac{d}{2}$, or

$$M = \frac{.098d^4}{\frac{d}{2}} \times S \text{ or } M = .196d^3 \times S.$$

That is, $d^3 = \frac{M}{.196 \times S} = \frac{M}{.196 \times 50000}$.

Substitute for M its valve for a 10-inch hollow shaft—(1), and we have

$$d^3 = \frac{954.9 \times 50000}{.196 \times 50000 \times 5} \text{ or } d^3 = 4871.93$$

and d or diameter = 9.24 inches.

Thus it is seen that the 0.76 inch added to the outside diameter is equal in strength to the 4 inches taken from the center.

Question.—A machinist uses a 48-inch double-ended tap wrench to tap a 1¼-inch hole. If he can exert 75 pounds pressure with each hand, what size square would be required on the shank of the tap?

Answer.—Formula $\frac{M}{S} = \frac{J}{c}$. Consider effective length of wrench on one end to be 22 inches, then

M = 22 × 75 × 2 = 3,300 inch lbs.

S for tool steel = 80,000.

J for square shaft = $\frac{1}{6} a^4$ where a = length of side, and $c = \frac{a}{2}$. Formula

becomes $\frac{M}{S} = \frac{\frac{a^4}{6}}{\frac{a}{2}}$ or $\frac{M}{S} = \frac{a^3}{3}$.

Or $a^3 = \frac{M}{S} \times 3$, or $a^3 = \frac{3300}{80000} \times 3$,

$a^3 = .12375$, and a = .498, or say ½ inch.

For safety this should be doubled or should be 1 inch square.

Question.—A 4-inch shaft has two keyways at right angles to each other 1 inch wide and ½ inch deep. What per cent. of the strength of the shaft would be removed in cutting these keyways?

Answer.—The strength of the uncut shaft can be represented by $M = \frac{J}{c} \times S$ inch pounds, and for a 4-inch shaft this would be $\frac{.098d^4}{2} \times S$.

$$= \frac{25.088}{2} \times S = 12.544 \times S.$$

A little observation will show that cutting a key-way 1 × ½ inch is practically the same as cutting out a section 1 inch long from a ring 4 inches outside diameter and 3 inches inside diameter. The mean diameter of this ring is 3.5 inch. Its length, therefore, is $3.5 \times 3.1416 = 10.995$. The length cut out by two key-ways is 2 in. This is $\frac{2}{10.995} = .1819$ of the strength of the ring.

The strength of the complete ring may be represented by $M = \frac{J}{c} \times S$ inch pounds.

Where $J = .098\ (d^4 - d_1^4)$,

d = outside diameter and d_1 = inside diameter; or,

$J = .098\ (256 - 81) = .098 \times 175 = 16.450$, and $c = 2$.

Therefore, $M = \frac{16.450}{2} \times S = 8.225 \times S$, and strength removed by key-ways $= 8.225 \times S \times .1819 = 1.496 \times S$.

Strength of whole shaft is represented by $12.544 \times S$, and the percentage that 1.496 is of 12.544 is $\frac{1.496}{12.544} \times 100 = 11.98\%$. Ten per cent. is usually allowed for key-ways.

Question.—An arm, rotated by a solid cast-iron shaft, is required to lift 360 pounds at a point 8 ft. from the center of the shaft. What should be the diameter of the shaft?

Answer.—Use formula $\frac{M}{S} = \frac{J}{c}$.

$M = 360 \times 8 \times 12 = 34{,}560$ inch pounds.

Average ultimate shearing strength of cast-iron is about 18,000 lbs. per sq. in., and allowing a safety factor of 4, the working stress or "S" becomes $\frac{18.000}{4} = 4{,}500$ lbs. per sq. in.

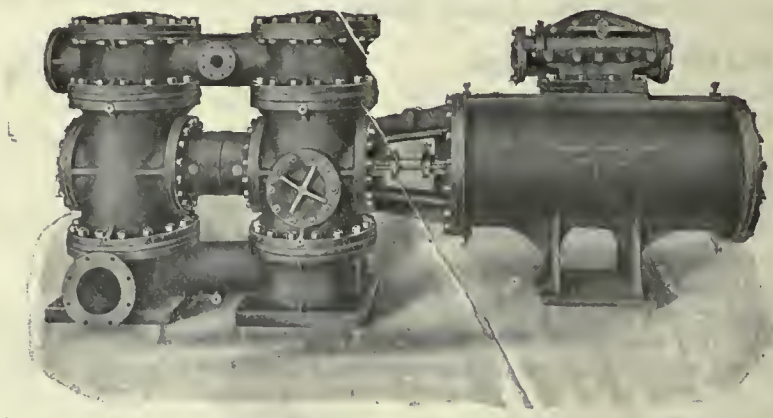
J for round shaft $= .098d^4$, where d = diameter of shaft and $c = \frac{d}{2}$.

Formula now becomes $\frac{M}{S} = \frac{.098d^4}{\frac{d}{2}}$,

or $\frac{M}{S} = .196d^3$, or $d^3 = \frac{M}{S \times .196}$.

Putting in valves, $d^3 = \frac{34{,}560}{4{,}500 \times .196} = 39.184$.

Diameter or $d = \sqrt[3]{39.184} = 3.39$ inches, or approximately 3⅜ in. shaft.



BAWDEN PATENT COMPOUND SINGLE-STROKE DOUBLE-ACTING STEAM PUMP.

FIRE TUG PUMP TEST.

FOR fire protection purposes along Toronto harbor front and across the bay at the Island, the tug T. J. Clark has had installed a Bawden patent compound, single stroke, double-acting steam pump, having high pressure group valve type water end. The duty requirement was 1,000 gallons per minute against 580 ft. head; with steam of 135 pounds per sq. inch on the piston of the high pressure steam cylinder. The pump cylinders are 14 in. and 24 in. diameter at the steam end, 12 in. diameter at the water end; the stroke of all being 20 inches. Bawden steam operated piston valves are fitted to the steam cylinders.

Tests of the pump were made at Centre Island on May 13, in the presence of Fire Chief Thompson and other officials, the results of which were highly satisfactory to all concerned; the required capacity being attained against a head of 635 feet. Test No. 1 consisted of pumping through two 500 ft. lengths of 2½-in. hose, fitted with 1¼-in. nozzles. Test No. 2 consisted of pumping through two 750 ft. lengths of 2½-in. hose, also with 1¼-in. nozzles; each of which threw a steady non-pulsating stream of 164 feet.

Although this type pump was illustrated and described in a former issue of Canadian Machinery, it may not be out of place to again draw attention to the more prominent features of this Bawden pump. The high and low pressure pistons work in one steam cylinder, while the steam ports are short and so arranged that the exhaust from the high pressure cylinder to the low pressure cylinder never leaves the main cylinder casting. Radiation and condensation are thereby reduced to a minimum. Only one steam chest is required, one valve distributing the high and low pressure steam. Owing to the absence of all external valve gearing, a high piston speed may be got if required, and during the progress of the foregoing tests as high as 172 ft. per minute was recorded.

TESTS OF BAWDEN PATENT COMPOUND SINGLE-STROKE

DOUBLE-ACTING STEAM PUMP AT TORONTO ISLAND.

PROGRESS IN NEW EQUIPMENT

A Record of New and Improved Machinery and Accessories for the Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

STEAM OR AIR LIFT DROP PRESS.

SHEET metal construction ras developed so much in the past ten years as to call for a class of machinery of much greater capacity than was formerly reqnired, and much originality has been necessary to meet the new condi-

STEAM OR AIR LIFT DROP PRESS.

tions. Sheet metal machinery of varying type and size is now bnilt, embraeing many special types.

The drop press has developed from very small size hammers up to very large machines capable of producing such work as automobile bodies, burial caskets, kitchen sinks, plates for ceiling and wall covering, as well as many other articles that were formerly castings. In smaller sizes of drop presses the lifting of the hammer was usually done by means of a belt hung over a flange pulley which ran continuously. A slight pull upon the belt by the operator enabled him to lift a considerable weight of hammer. The rope also has been used extensively, it being coiled several times around a drum which runs continuously.

These methods of lifting are quite satisfactory when the hammer is of light weight, but the friction in either case on the drum or pulley generates an amount of heat that on the larger sizes burns out the belt or rope; very considerable power is also consumed. In the larger sizes, water circulation is used in an enclosed drum for the purpose of carrying off as much heat as possible, but even this method does not save the rope or belt, and the cost of replacing same is a very considerable item of expense. In all cases the consumption of power is large for the work done.

In order to meet these objection the Henderson Machine Co., of Philadelphia, Pa., have designed a drop hammer to lift by means of steam or air. A special design of steam cylinder is employed, while a special valve is used for the admission and escape of steam or air. The rapidity of lift of hammer is entirely under control in the matter of speed. The operator can, therefore, throw the admission valve wide open and the hammer will lift only at the speed at which the device is set, making operation absolutely safe in the hands of the most careless.

These machines, we understand, have been thoroughly tested out, and give proof that under ordinary conditions they are capable of more work than the frictional lift hammer, and with less than one-third the consumption of power. In coaxing operations where the hammer is raised and dropped a very small amount repeatedly, in order to gradnally bring up a design in sheet metal, rapidity of handling is a feature.

The hammers are made up to 46 ins. x 72 ins. faec, weighing in the latter size about 10,000 lbs., with an entire weight of about 60,000 lbs. The accompanying cut shows a size of whieh the hammer is 36 ins., x 60 ins., and total weight about 40,000 lbs. It will be noticed that, in the design of the bed of the machine, all projections are tapered so as to avoid shrink strains that would otherwise oeenr in so large a mass. The upper works are made massive for the purpose of absorbing shock due to the fall of the hammer. The latter is an open hearth steel easting, designed with large fillets in all corners. The piston rod is attached to the hammer in such a manner that no shock is transmitted to it when the hammer falls. Radical improvements have been made in these machines by which durability of the working parts, quick action, and ease of handling have been secured.

NEW ENGRAVING MACHINE.

SCHUCHARDT & SCHUTTE, New York, are about to put on the market an improved machine for all forms of engraving on different metals. It is particularly suitable for the cutting of trademarks, name-plates, letters and figures, as well as the making of small dies and similar parts.

The machine operates on the pantograph principle, a pattern of the required design being slipped into a slot in the pattern table and strapped in place. At one end of the pantograph there is a guiding point which is brought into contact with the pattern and run over it, and the engraving tool is carried by a spindle at the opposite end of the pantograph. The movement of the guiding point over the pattern causes the engraving tool to follow exactly the same course. Three of the arms on the pantograph are provided with scales by means of which the relation between the lengths of the arms can be adjusted to obtain any desired size for an engraved design, the limit of the machine being from a ratio of 1 to 1 between the size of the work and the pattern down to a ration of 1 to 10 between the work and the pattern. Where only a few pieces are to be engraved, the design drawn on Bristol board can be used for a pattern.

In addition to having the engraving tool guided over the work by means of the pantograph, the tool must rotate at a high speed.

A brief consideration will suffice to show that the movement of the tool by

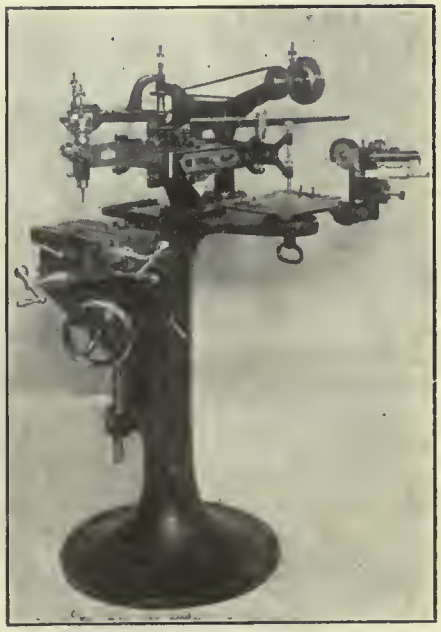


FIG. 1—SCHUCHARDT & SCHUTTE ENGRAVING MACHINE.

means of the pantograph makes it necessary to provide a flexible system for supporting the driving pulleys. The way

in which this is arranged through three sets of pivoted arms is clearly shown in Fig. 2. One of the difficulties which has been experienced with engraving machines working on the pantograph principle, is that the bearings supporting the tool spindle become worn through the belt pull, thus causing a serious inaccuracy in the work produced by the machine. In the new Schuchardt & Schutte engraving machine, this difficulty has been overcome by employing the extended sleeve construction which has been successfully applied in various classes of machine design, for eliminating unnecessary strain on the bearings. This sleeve extends up from the main spindle housing, between the spindle and the driving pulley, so that the belt pull is supported by the sleeve rather than the spindle bearing, and, in this way, unnecessary wear of the bearing is avoided.

In Fig. 1 a small grinding attachment is shown bolted to the pattern table. This attachment is used for grinding the engraving tool. It will be seen that there is a two-step cone pulley at the right-hand side of the machine, which is not shown with a belt running over it. One of the steps on this pulley is connected to the source of power which drives the machine, and the other is used for carrying the belt which transmits power to the grinding attachment. One of the engraving tools is shown set up in the horizontal chuck, with its point in contact with the grinding wheel.

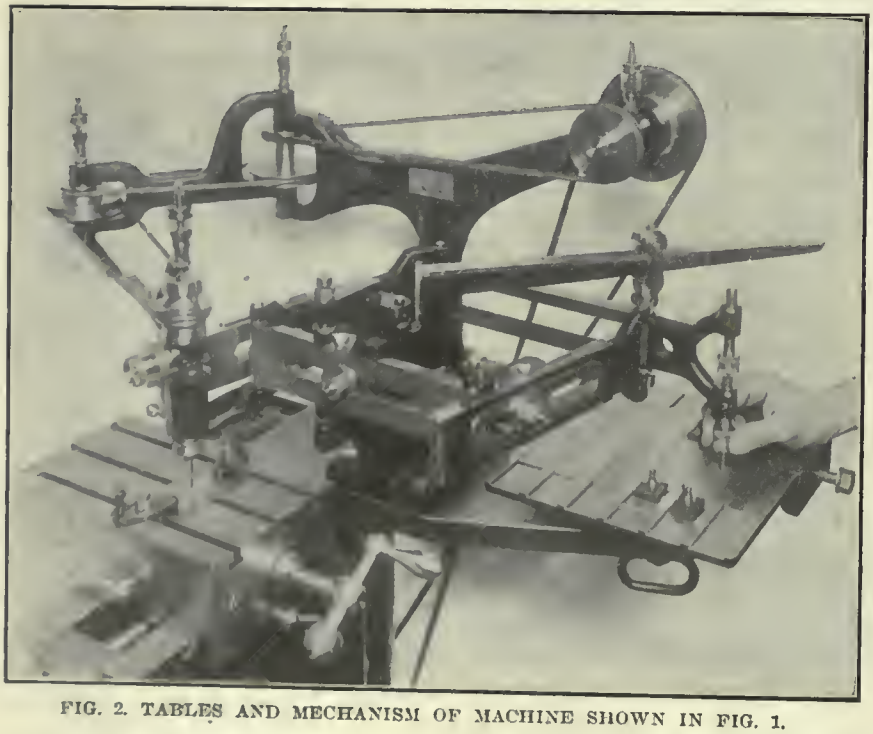

FIG. 2. TABLES AND MECHANISM OF MACHINE SHOWN IN FIG. 1.

In setting up this tool ready for grinding, the first step is to have it accurately centered. This is done by bringing the point of the tool into contact with an index point on the end of a pin, which is set up in the bed of the grinding attachment. The engraving tool is cylindrical in shape and, for about 1½ inches at its lower end, a flat is ground which

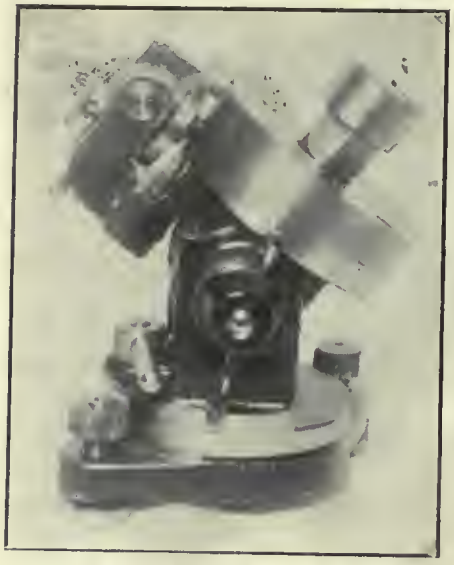

FIG. 3. DIVIDING HEAD FOR USE ON ENGRAVING MACHINE.

removes about one-half of the metal. The tool is not ground, however, by merely rotating it about its axis with the tool in contact with the wheel. Experience has shown that the best results are obtained by having the ground surface of the tool of an elliptical section instead of circular, and this special form is obtained by controlling the motion of the tool when in contact with the grinding wheel, by means of a cam located at the far end of the tool-holder. The grinding attachment is bolted to a lug on the under side of the pattern table and may be quickly removed by simply loosening one bolt.

Fig. 3 shows an attachment for use on this machine, which provides for engraving on cylindrical or conical surfaces or on flat dials on which it is required to engrave at equal intervals. The attachment is essentially an arbor on which the work can be mounted, with provision for rotating this arbor through any required angle between successive engraving operations.

For engraving on cylindrical or conical surfaces, it is obviously necessary to have the element of the surface on which the engraving is to be done held in a horizontal position. This is done by loosening the wing nut and then swinging the arbor down to the required angle. In most cases, where engraving is to be done on such surfaces, the pattern itself is flat and strapped to the pattern table in the usual way.

Another useful attachment for use on this machine is one for use in engraving on concave or convex surfaces. For work of this nature it is necessary to have the engraving tool work to a constant depth, but the tool must also follow the contour of the work. This is done by having a master blank of the required form located on the lower support of the attachment. A guide point runs over this master blank and controls the movement of the engraving tool, which is in contact with the work carried on the upper support of the attachment.

The design of the machine has been carefully worked out to give it the necessary rigidity for withstanding hard service. When desired, three different styles of pattern letters and pattern numbers can be supplied. Many manufacturers, however, prefer to use some other style of patterns, and these can be made direct on the machine. The same statement, of course, applies to the production of patterns for trade-marks, name-plates, and similar designs. The operation of the machine is so simple that it has been found that a boy or girl of average intelligence can be taught to use it and obtain very satisfactory work. These machines will be marketed in Canada through the Canadian office of the company at 42 Adelaide Street, Toronto, Ont.

THE SHAW ELECTRIC MONO-RAIL SYSTEM.

QUITE an interesting application of the overhead mono-rail system to the requirements of inter-factory transportation, coal and ash handling, and like service is to be noted in a recent development by the Shaw Electric Crane Co.,

New York. The distinctive feature of the Shaw mono-rail system is the absence of any moving part in the track switch.

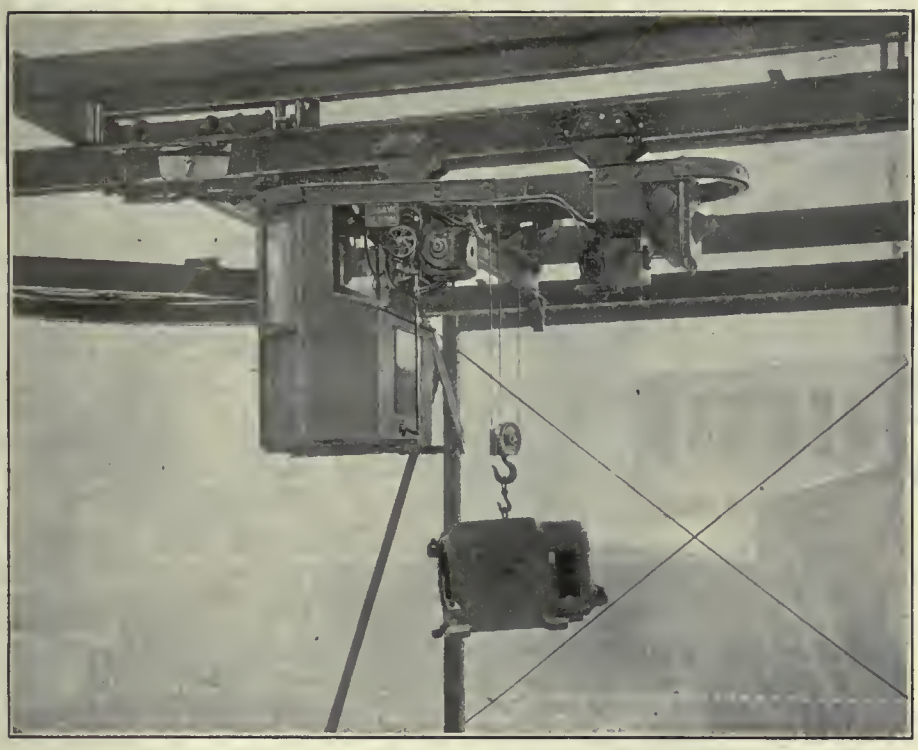

FIG. 1. TYPICAL TWO-MOTOR MONORAIL HOIST.

The main advantage claimed for the Shaw fixed-tongue track switch lies in the fact that it does not have to be set for the desired direction of travel, consequently there is neither delay nor expenditure of effort for this purpose. The operator in the cab selects his route and the trolleys run through the track switches in all directions and without stopping. There being no open ends of the track to be protected, and it is therefore impossible for the trolley to break through and fall. Safety as well as increased range of service are thereby secured, while the operator in the cab has independent and absolute control, both of the route, hoisting and travel operations. A typical two-motor monorail hoist of the type under discussion is illustrated in Fig. 1.

Negotiating the Fixed Switch.

The cast-steel "fixed-tongue" track switch, illustrated in Figure 2, shows clearly the two slots in the switch through which one truck side passes, the slot at the left, A, when the trucks run through the switch, and the slot at the right, B, when the trolley is diverted to the spur track. In either case, the truck wheels run over the gaps, but the

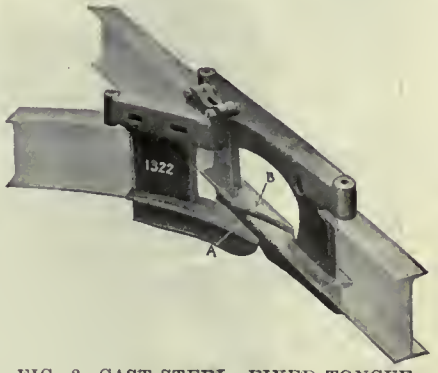

FIG. 2. CAST-STEEL, FIXED-TONGUE TRACK SWITCH.

wheel-base of the truck is so proportioned with reference to the slots that three wheels always ride on the runway flanges, and furthermore, the wheels bridge the gaps at such an angle that the break is only nominal.

The manner in which the leading truck is steered off on the spur track is shown in Fig. 3, which is a sectional plan at the level of the lower flanges of the I-beam track. This shows a right-hand switch and also the truck sides of the trolley. When approaching the track switch with the intention of running off on to the spur, the horizontal roller, T-2, located in the front of the leading truck, is raised by the steering lever in the cage and engages the curved flange B on the under side of the central tongue of the switch (the advance end of the guide flange is shown in Fig. 2). In this manner the leading truck is swiveled and diverted on to the spur track, but no steering operation is necessary to return from the spur to the main track nor to run through the track switch in either direction on the main line.

Keeping the Train Intact.

The scheme whereby the trailing truck is compelled to follow so that the trolley cannot possibly split the switch, is equally interesting. Referring to Fig 4, the smaller diagram, drawn to a larger scale, is also a sectional plan, but at the level of the trolley frame which joins the two trucks and supports the hoisting machinery. It shows only the rear truck and a portion of the trolley frame.

Lines L, R and F represent the centre lines respectively of the leading truck, the rear truck and the trolley frame. The trucks swivel on the trolley frame through an angle, A in the case of the rear truck, and as indicated in the lower diagram, angle A is limited by an adjustable set screw S-1 in truck side R-1.

Assuming both trucks to be on the main track and approaching the switch, the centre lines L, R and F would then lie in a straight line, and the angle A would be zero. As the leading truck proceeds around the curve of the spur, the trolley frame swings around with reference to centre line R of the rear truck and the angle A increases. When the rear truck reaches the point where the curve begins (as shown in the diagram), the set screw S-1 engages the frame casting and angle A has attained its maximum value as the trolley proceeds beyond the position shown in the

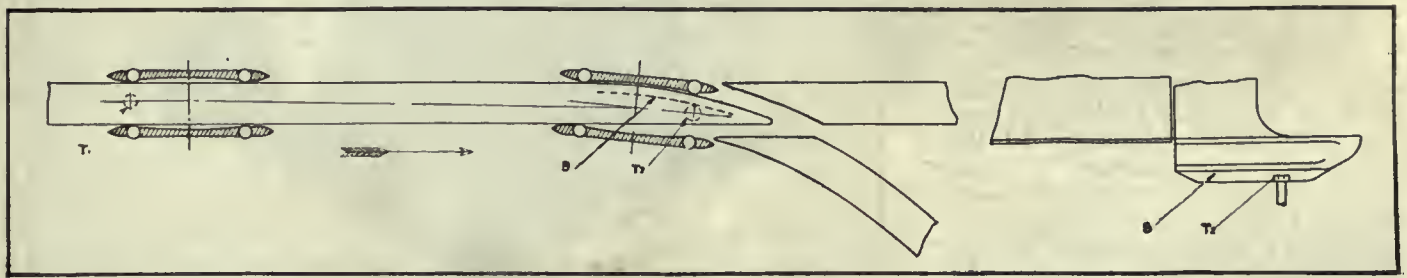

FIG. 3. SECTIONAL PLAN AT LEVEL OF LOWER FLANGES OF I-BEAM TRACK; MAIN ILLUSTRATION SHOWS RIGHT-HAND SWITCH; AT THE RIGHT, TRUCK SIDES OF THE TROLLEY.

sketch. The frame casting slews the rear truck around and compels it to follow on to the spur track.

Independent of Steering Gear.

It should be noted that the arrangement is positive and independent of the initial steering operation. The only essential condition is that all curves on the same track system must have the same radius for an arc whose chord is the center line F, as this arc determines the angle A, for which the set screw S-1 is adjusted; beyond this arc any longer radius may be employed.

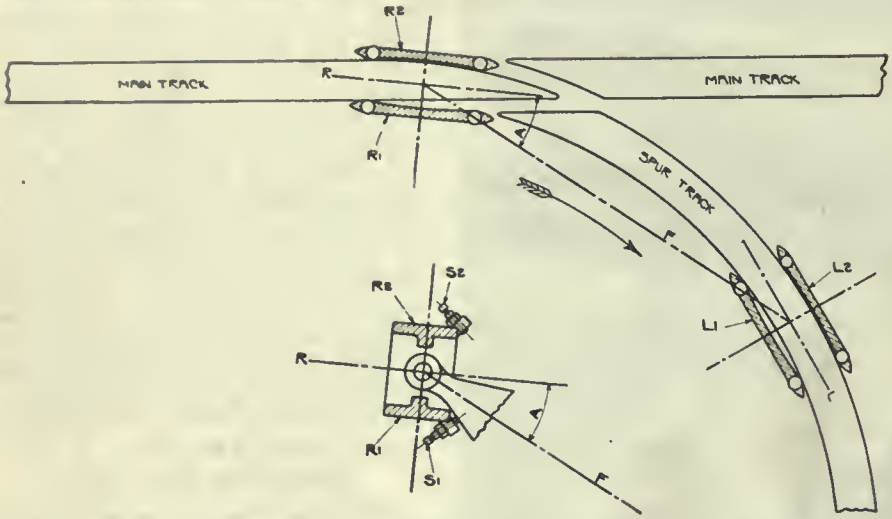

FIG. 4. DETAILS OF SWITCHING ARRANGEMENT, SHOWING METHOD OF KEEPING TRAINS INTACT.

The diagram shows a right-hand switch, but it will be noted that set screw S-2 in the truck side R-2 provides for left-hand switches. It is, of course, understood that the trolley travels either end ahead, that both trucks embody the steering feature, and likewise that both trucks have the set screws as described.

While this mono-rail is comparatively new, we understand several successful installations in capacities ranging from two to six tons have been made. The hoist is built either with the single lift, as shown in Fig. 1, or with a double hoist for handling the ordinary "two-line" clam-shell grab-bucket, two separated holding lines being employed to prevent swiveling of the bucket.

Manning, Maxwell and Moore, New York, are sales agents for the Shaw Electric Mono-rail System.

DIRECT CONNECTED MOTOR-DRIVEN GRINDER.

MORE or less difficulty has been experienced in devising a lubricating system which will automatically oil the radial and thrust bearings in disc grinders. Charles H. Besley & Co. of Chicago have designed a machine which through an ingenious system of ring oilers appears to have overcome the problem.

The grinder has been thoroughly standardized and all the working parts are renewable. The bearing bushings are of cast iron lined with heavy metal, while the backs of the liners are ground, and fit into carefully bored and reamed holes. The motor shaft is made from hard crucible machinery steel, and the wheel collars are drop forged from hard machinery steel. The end thrust in both directions is taken up by hardened and ground tool steel thrust collars of large area running at each end of the right hand bearing bushing. One of these collars is threaded on the spindle and the end thrust is thus taken care of.

The motor, of 7½ h.p., is fully enclosed, and can be operated on 60 cycle alternating current or on 25 cycle. Suitable discs are supplied to give the correct abrasive speed in each of the two cases. The machine illustrated is equipped on the right with a geared lever feed table, and on the left with plain tilting-table.

The general dimensions of the machine are:—

Spindle—2 in. diam. by 29½ in. long.

Length of each bearing bushing, 6 in.

Rockershaft—2½ in. diameter by 57½ in. long.

Height to center of spindle—40 ins.

Floor space of bed casting, 28 in. by 28 in.

Weight complete with all equipment, 2,000 lbs.

SQUARE END PIPE CUTTER.

IN placing this new 2½ in. to 4 in. pipe cutter on the market the Borden Canadian Co. of Toronto have made a radical departure from the standard design of pipe cutting tools.

The tool consists of two sections, the gripping part, which when in operation has no motion relative to the pipe, and the cutting part, which revolves about the latter. Figs. 1 and 3 show these two

DIRECT CONNECTED MOTOR-DRIVEN GRINDER.

sections respectively. To cut off a piece from a pipe, the first operation is to clamp the tool to the pipe. In Fig. 1 the gripping jaws seen are closed by a right and left hand grip screw which

FIG. 1. PIPE GRIPPING SECTION A.

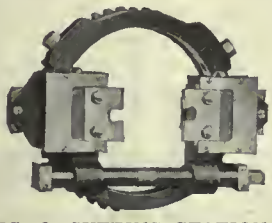

FIG. 2. CUTTING SECTION B.

is operated by a wrench fitting over its square end. In Fig. 2, showing the cutting section, a similar right and left hand screw sets the knives up against the pipe under tension. The cutting section has a ratchet fitted to it, and by means of a handle fitted into a link on the gripping section, the cutting part is thus made to revolve about the pipe, being actuated through the lever and the ratchet. The knives are fitted with little blocks, and when placed up against the pipe under tension, coil springs behind these blocks are compressed and keep the knives uniformly against the pipe as the cut proceeds. The knives are so shaped that part of the cutter forms a guide which allows the feed never to exceed that for which the cutter was designed. The springs pressing against the little blocks keep the tool always cutting; thus when once set against the pipe the feed is automatic and constant. The tool is a complete unit of cast steel, and a bronze bushing is provided for a bearing surface upon which the cutting section revolves.

Fig. 3 shows the assembled tool. When the jaws are clamped to a pipe they automatically center the cutting knives so that the pipe is cut off square. As the cutting is done by means of a ratchet, pipes may be cut off in cramped places which would otherwise prohibit the use of an ordinary tool. One man can work the pipe cutter to advantage. In fact, the tool, we understand, is capable of cutting off a 4-in. pipe in four minutes by a man using one hand only. The cut is particularly clean, there being a conspicuous absence of burrs inside and outside. There is, further, little tendency to strain, distort or split the pipe, while the cutter can be quickly adjusted to fit any size from 2½ in. to 4 in. The tool will also cut through a thread as quickly and squarely as a piece of straight pipe.

Two extra sets of cutters are supplied with each tool and also a template for grinding. The knives are easily and quickly removed by simply taking out two cap screws. There are practically no parts to get out of adjustment.

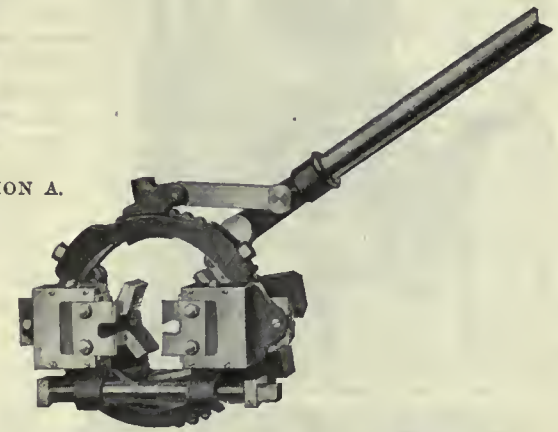

FIG. 3. 2½-4 IN. SQUARE END PIPE CUTTER.

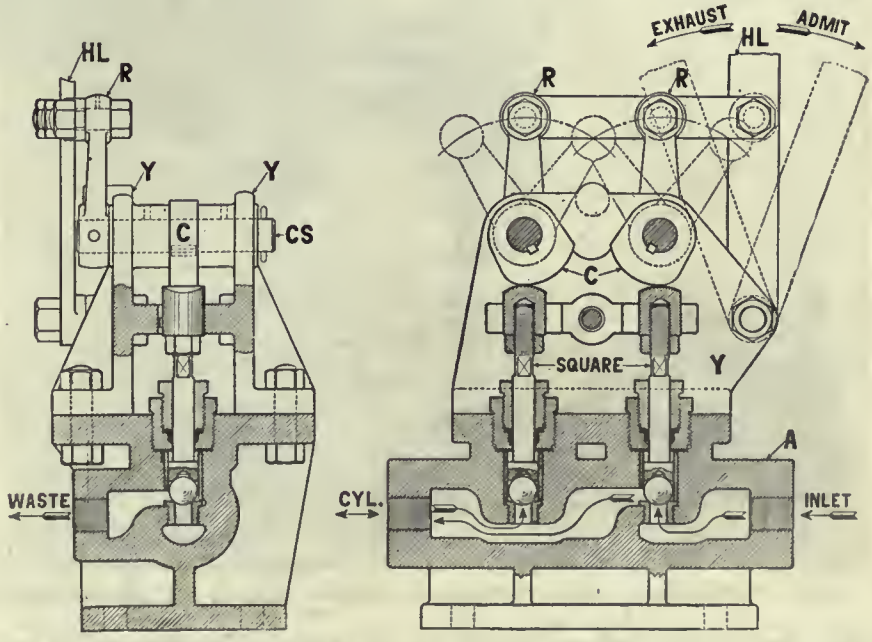
SCHNICKE HYDRAULIC OPERATING VALVES.

FROM time to time operating valves for hydraulic machinery have been designed and placed upon the market. In the Schnicke type the idea of a ball valve has been employed, which makes the operation very simple and reduces the chance to a minimum of any working part becoming damaged.



SECTIONAL VIEW, SCHNICKE THREE-WAY HYDRAULIC OPERATING VALVE.

The valve is most easily described by referring to the accompanying cut. The horizontal valve chamber A is provided with pressure and waste ports and is machined to receive stuffing boxes, bushings and slot rings. To the top of the valve chamber are bolted the yokes Y, which form the bearings for the end of the cam-shafts, CS. To these cam-shafts are securely bolted the cams C, and the rocker arms R.

The cams are operated by the hand lever, H L, which is attached to the rocker arms. Seat rings of proper proportions are screwed into the pressure and waste ports of the valve chamber. Between the seat and the stem, a hard bronze ball is employed, the motion of which is controlled by the cam. The upper end of the stem is threaded into a bearing nut, and is also provided with a jam nut and square. These bearing nuts travel through a web in the yoke castings, while the lower part of the stems are held in position by the stuffing box glands and bushings; thereby ensuring proper alignment of the stems at all times. The cams are so designed and are keyed to the shaft in such a manner that when in operation the pressure port is closed before the waste port opens and vice versa.

When the hand lever HL is thrown in the direction to admit the fluid under pressure the ball in the admission valve is forced off its seat and the fluid passes to the machine. To open the waste port, the hand lever HL is thrown in the opposite direction, and then the fluid escapes through the exhaust valve, which is opened by the fluid pressure in the machine. The square section on the valve stem, as well as the bearing nut and locking nut, being on the outside of the valve, are all readily accessible and permit of rapid and easy valve adjustment under working conditions. This allows the operator to keep his valves

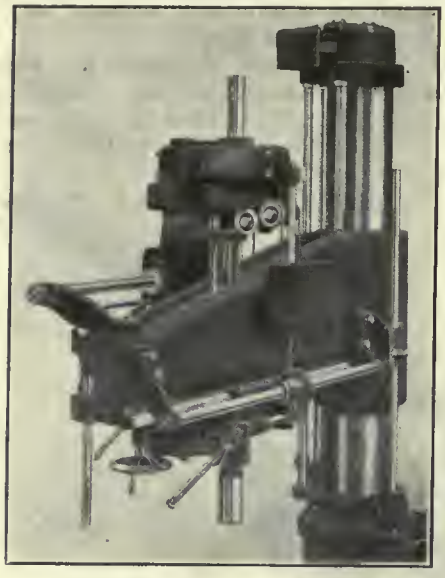
tight and thereby prevent leakage and to reduce repairs and upkeep to a minimum.

For pressures up to one thousand pounds, the bodies are made of air-furnace iron, and for pressures in excess of this, open-hearth steel or hydraulic bronze is used. The Schutte & Koerting Co., Twelfth and Thompson streets, Philadelphia, are marketing the above product in sizes from ¾ in. to 2½ in., and in three and four-way form with either screwed or flanged connections.

CENTRAL THRUST RADIAL DRILLING MACHINES.

IN the design of radial drilling machines the central thrust type seems to be a universal favorite. The Selson Engineering Co. of Coventry, England, have placed upon the market an attractive design of this type of machine, which they are building in two sizes; one with a radial arm of 4 ft. 6 in., and the other with an arm of 6 ft.

The principal feature of these machines is that the thrust of the spindle is in line with the center of the arm, and column. Thus all side twisting strains are entirely avoided. The carriage is in the form of a right angle, and is securely gibbed to the front and underside of the arm. The front plate carries the top bearing of the spindle, driving gears, and feed mechanism, while the under plate forms the lower bearing and takes the central thrust of the drill. The back gear is placed directly on the spindle, as also are the reversing gears. These latter are driven by powerful, specially designed clutches,



BACK VIEW OF ARM, 6' 0" SELSON RADIAL DRILL.

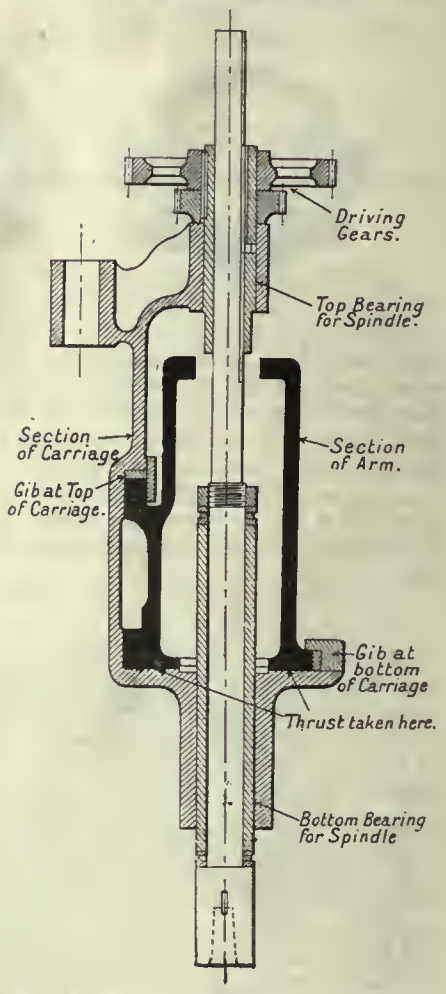
which can be thrown in and out when running at any speed.

The carriage is moved along the arm by a hand-wheel, and the arm has an extra long bearing on the column to prevent deflection, while its own cross section is so designed that great strength is obtained without having an abnormally heavy arm.

The spindle is of high carbon steel and runs in a long sleeve of large diameter, which prevents any deflection when in its lowest position. Both spindle and sleeve pass throuh a slot in the arm, and thus all the side twisting strains are avoided, because the thrust is directly in the center of the arm.

The starting, stopping and reversing operations are effected by one hand-lever in front of the carriage and the machine can be reversed at a greater speed than that at which it works; thus taps can be quickly withdrawn. All thrusts are taken by ball bearings, and hand traverse is provided as well as quick withdraw motion.

The column is of large diameter and



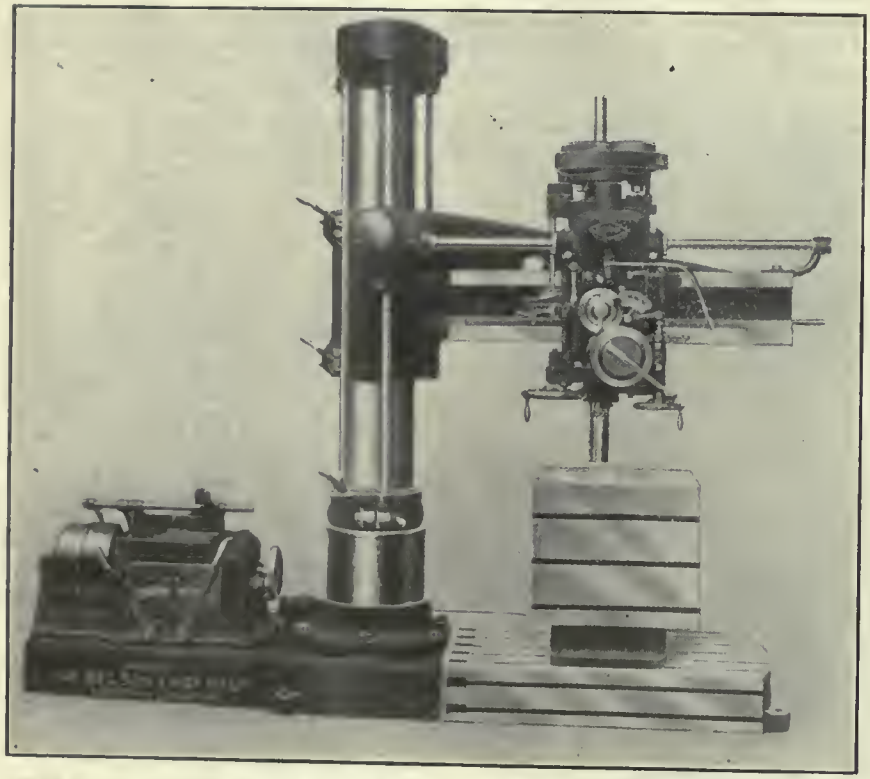
SECTION THROUGH ARM AND CARRIAGE.

rests on ball bearings, while the swivelling can be easily accomplished and the column locked in any desired position. The driving gear is extra powerful and arranged for taking heavy cuts at high speeds. Another feature is that the double back gear is placed directly on the spindle avoiding the undue torsion of long driving shafts. Every locking motion is provided with a handle, therefore spanners are superfluous.

The three outstanding advantages of this machine are:—

(1)—Central thrust eliminating all torsional strain.

(2)—The arm slot is of minimum



SELSON 4' 6" RADIUS, PATENT CENTRAL THRUST HIGH SPEED RADIAL DRILL.

width between walls giving greater stiffness without unnecessary weight.

(3)—The carriage is gibbed to the arm at front as well as at the bottom, thus giving greater rigidity to top spindle bearing and preventing vibration.

The British Manuacturers' Association of Canada, Limited, are the sole agents for the Dominion of the Selson Engineering Company.

Miscellaneous

The Hare Engineering Co., Ltd., 78 Duchess Street, Toronto, manufacturers of mechanical stokers and power plant equipment, have appointed Frank Darling & Co., 1142-1144 Homer Street, Vancouver, B.C., as their British Columbia agents.

The Engineers' Supply Co., 123 Bannatyne Avenue East, Winnipeg, have been appointed agents in Western Canada for Belmont packings, manufactured by Clement Restim Co., Philadelphia. They are also agents for the Hill safety gauge glass.

Canadian Exports.—The revised summary of Canadian trade for the twelve months ended May 1 shows an aggregate of $1,096,883,675, as against $1,079,934,000, an increase of about $17,000,000. There is a big increase in exports and a falling off in imports. Imports in the twelve months totalled $621,822,564, a decrease of $57,000,000 compared with the last year. Exports totalled $475,061,111, an increase of nearly $74,000,000. The biggest increase was in agricultural produce, totalling $38,000,000, while manufactures exported increased $14,000,000. In imports there was a decrease of $12,000,000 in purchases from the United States and $40,000,000 in purchases from the United Kingdom.

The John Bertram & Sons Co., Ltd., Dundas, Ont, and its associate company, **Pratt & Whitney Co. of Canada, Ltd.,** will on July 31 discontinue the arrangement with the Canadian Fairbanks-Morse Co., who have acted as sales agents for the above two concerns for the past few years. The John Bertram & Sons Co. have organized a sales staff, and will establish offices in several different centres. The head office will remain in Dundas, as formerly, while the principal Eastern sales office will be at 723 Drummond Building, Montreal, in charge of Colonel Alex. Bertram, who will hold the position of general sales manager. The Ontario section will be handled from Dundas. An office has been opened at Winnipeg, in charge of Alfred Martin, formerly of Mussen's, Ltd., Montreal. Colonel Bertram is at present in Vancouver arranging for an office there, and particulars of this will be announced at a later date. The product of John Bertram & Sons Co. and Pratt-Whitney Co., of Canada, will be handled by these various sales offices.

THE LATE DEAN GALBRAITH.

WITH the passing of Dr. John Galbraith, Dean of the Faculty of Applied Science of Toronto University, the Dominion of Canada has lost a noted educationalist, scientist and citizen. Born in 1841 at Montreal of Scotch descent, his life work has been closely identified with the growth of the Dominion. The year of Confederation was the beginning of Canada's great industrial and railway development, into which Dr. Galbraith entered as a factor upon his graduation in the following year.

He studied engineering and surveying under Geo. A. Stewart, Chief Engineer

THE LATE PROFESSOR JOHN GALBRAITH

of the Midland Railway; was employed on the construction of the Intercolonial Railway and the Midland Railway extension to the Georgian Bay, and for several years was engaged on the construction of the Canadian Pacific Railroad. He, along with H. D. Lumsden, who is now chief engineer of the National Transcontinental Railway, became the division engineers of the Georgian Bay branch.

Dr. Galbraith made many trips through the wilderness of Ontario and Quebec and few were better able to equip and guide exploring parties than he. In the summer of 1881, unattended and for recreation only, he made the trip from Lake Superior via Michipicoten to Hudson's Bay, then via Rupert's River to Lake Mistassini and across the height of land to Lake St. John, reaching civilization by way of the Saguenay River.

Dr. Galbraith's academic career, though connected almost entirely with the University of Toronto, has been brilliant. Graduating from Port Hope grammar school in 1862, he went to Toronto and, finding that there was no school of engineering available, entered the university as a freshman in arts. He finished his college training in 1868 as Gold Medalist in honor mathematics and Prince's Prizeman of the University of Toronto. The Prince's Prize was a special prize for highest general proficiency, established by the Prince of Wales—Edward VII.—during his visit to Canada.

In 1878 he was appointed to the Chair of Engineering of the School of Practical Science which he largely organized himself. Dr. Galbraith was at first the only instructor, and his first class numbered less than 30 pupils. He was appointed to the principalship in 1889 and later became Dean of the Faculty of Applied Science and Engineering. He was one of the founders of the Canadian Society of Civil Engineers and was long a councillor thereof. He was elected to the presidency in 1909. He was also a member of Institute of Civil Engineers and has served as vice-president of the Canadian Institute of Toronto.

As Dean of the Faculty, Dr. Galbraith devoted himself almost wholly to the upbuilding of the School of Practical Science, steadfastly refusing to undertake any consulting or other work whatever that would in any possible way interfere with its welfare. Being a practical man himself, his policy has been, even against continued opposition, to equip his students with a thoroughly practical education. As a teacher he was strict and even stern in his administration of discipline and justice, but succeeded in winning the hearts and love of all with his inexhaustible humor and kindness of heart. The esteem and respect in which he was held by the students was best shown at the last annual dinner of the School of Science, when 600 engineers gathered from all over America in honor of the 50th anniversary of his association with the university.

His character was simple and rugged and his personality such that every student was wont to emulate him. To meet him was to feel in him a personal friend, and he never was so busy that he could not give his personal attention and counsel to the youngest student in need of it. The best evidence of his character and work is the high moral and professional standing of the graduates in all parts of the world and the fact that the most active supporters of the "School" are his former students. The secret of the regard in which he was held was aptly told by President Falconer in the few words, "A thoroughly trustworthy man, thorough in training, honesty and patience."

SELECTION OF A MANUFACTURING SITE.

PROSPECTIVE Canadian manufacturers have the advantage of much of the best experience of others in the selection of localities in which to carry on operations. The practice of foreign firms who have already won success in their home country is well worth a considerable amount of study. A large number of these now have branches located in Canada and are almost invariably successful.

The importance of choosing a site is at once apparent, for once located and built upon, it fastens the industry permanently to its conditions and surroundings. The great rise in values of real estate in the cities of late years has made it possible for many Canadian firms to sell out and remove to more advantageous locations without serious loss.

Outside of the usual considerations of the availability of power, supplies and transportation, and the value of public utilities and corresponding taxation there are other things which, though seemingly inconsiderable, will have a large aggregate effect upon ultimate success. Canada has possibly a greater variety of climatic, social and labor conditions to choose from than any other country and, while we may never experience extreme labor legislation as seen in some parts of the United States, it will be found that the labor conditions vary considerably, but in proportion to the cost of living, average better for the working man.

The effect of extreme climate is not usually considered, although the matter of heating runs from a few cents to fifty dollars per day. A single storm last winter cost a Michigan firm $6,000 in general damage and in the same plant an average of five days were lost from the same cause by every employee during the year.

Just as the character of the industry strongly influences the life of the place in which it is located, so the reverse is the case. One company having plants in two different parts of Canada has found that, in one of them the average working week is fifty-one hours as compared with fifty-four in the other under the same regulations. The difference in output per man is also noticeable.

THE VISITING OF FOREMEN.

THE article by Mr. Westbrook on another page of this issue strikes several important and original points in the efficient management of machine shops. There is nothing to prevent the making of arrangements among foremen for the interchange of visits for mutual benefit. The essential feature is, of course, a strictly friendly spirit of criticism and assured privacy of discussions. The management of a machine shop or foundry involves so many considerations that what might be considered perfection by one man could easily be much lacking in the eyes of another.

The personalities of different foremen are nowhere better seen than by visiting their different shops. It is astonishing to note how each place reflects all through the characteristics of a single man. Neatness or slovenliness, order or discord, and above all, application or delinquency of the "boss" are easily seen in the shop by the casual visitor. In fact, the shrewd seeker of employment can readily pick up some valuable hints on how to approach his prospective superior by noting the character of the place upon which that worthy has unconsciously placed his mark.

The few cases instanced by Mr. Westbrook go to show what can be done by one man, after another equally able has done his utmost. How shortsighted a policy it is, then, to place the earnings, character and reputation of a large investment irrevocably in the hands of a single man.

The greatest stumbling-block to the carrying out of the idea is, of course, the natural disposition of men, particularly in competitive institutions, to shun intimacy, a condition for which the management is often responsible. The writer is aware of cases where foremen of a common organization have never seen the plants of their company situated in different cities.

INDUSTRIAL NOTABILITIES--No. 45

WILLIAM FOSTER COCKSHUTT, M.P., merchant and manufacturer, ex-president Cockshutt Plow Co.; director Brantford Roofing Co., and director B. & O. Road Co., Queen St., Brantford, was born at Brantford, Ont., Oct. 17, 1855, the son of I. and Elizabeth (Foster) Cockshutt; of English descent, his father coming to Canada 1826. He was educated at the Brantford and Galt Collegiate Institutes.

In matters of trade and commerce, Mr. Cockshutt has been a member of the executive and councillor of the Toronto Board of Trade for 15 years; a former president Brantford Board of Trade; member Ontario Power Commission; was appointed a commissioner to investigate the development of electric power at Niagara Falls for distribution in Ontario, 1903; was six times delegate to Commercial Congresses of the

WILLIAM FOSTER COCKSHUTT, M.P.

Empire, 1906; delegate to British Imperial Council of Commerce, 1911; and has traveled throughout the Empire lecturing on "Empire Unity and Preferential Trade." As member for Brantford in the House of Commons, Ottawa, he has done effective work in debate and otherwise for the Conservative party. He is an ardent Imperialist as the foregoing amply indicates.

He is chairman the Laycock Orphanage; president Bell Telephone Memorial Association; member Executive Committee, Bible Society of Canada; member of the General Synod; member Huron Synod of the Church of England; was presented to King Edward in 1906, and represented Brantford at funeral in London, England, of His Majesty King Edward in 1910.

Mr. Cockshutt married Minnie Turner Ashton, daughter of Rev. Robert Ashton, Brantford, Ont., Aug., 1891, and there are four sons and two daughters of the union.

The General Market Conditions and Tendencies

This section sets forth the views and observations of men qualified to judge the outlook and with whom we are in close touch through provincial correspondents.

Montreal, July 27, 1914.—During the past week there has been little change in machinery circles; most of the supply houses here, however, looking for improved conditions shortly. Orders are still very scarce, but several dealers are figuring on the machinery for the Grand Trunk Pacific Railroad, details of which are to be found on page 111.

Building operations continue about the same. There are practically no large contracts, but small work seems fairly plentiful. During the week contracts totaling about $700,000 have been let by the different Roman Catholic authorities for church and educational buildings.

This city will shortly call tenders for 200 lamp standards, with cable connections. The new standards will be of the single lamp type, and will be placed 120 feet apart, with two at all street corners. These lamps are for connection with the underground conduits now completed. There is considerable of this work under construction, which when completed will require several hundred additional lamp standards.

Figures issued by the building inspector's department at the City Hall show a decrease in the value of building permits for the first six months of 1914, as compared with the same period in 1913.

Metals.

There has been little change in the position of the metal market. For the past week or ten days dealers here had been reporting that prospects looked brighter; in fact, they seemed very hopeful of the future, but developments in Europe at the week-end cast a shadow over an otherwise promising situation. Already there is a slump in some prices, copper being quoted this morning 25 cents less than a week ago.

Sterling quotations to-day are:—Tin, spot, £136 15s.; future, £136 10s.; copper, spot, £58 10s; future, £59 17s. 6d.; lead, £18 10s.; spelter, £21 12s. 6d.

Toronto, Ont., July 26, 1914.—Generally speaking, business conditions do not show any marked change this week, although a more optimistic spirit is noticeable. There is no improvement in external political conditions, which are still having an adverse effect on the money market. Crop reports vary according to the districts from which they emanate, but they are on the whole favorable, and are giving a certain amount of buoyancy to conditions generally.

There is not much doubt but that we are passing through the dullest times in business that have been experienced for years, and as we have gradually come to the condition, so must we gradually emerge until normal times are again reached. Reports from various points indicate that business is improving and that prospects are brighter. An immediate return to normal conditions is not to be expected, but rather a continuance of the gradual improvement that is already taking place.

Steel Market

No improvement is as yet noticeable in the iron and steel trades, although a return to better conditions in the near future is anticipated by many. A prominent official of the G.T.P. stated recently that large orders for equipment have been considered and arranged for, but not issued. It is highly probable that these orders will be held up for some considerable time pending a completion of the necessary financial arrangements. The building trade continues quiet in so far as it affects the steel trade. A considerable amount of steel will be required for the new

Registry Office building, tenders for which were opened here last Thursday.

Interesting news comes from Pittsburg this week to the effect that all the leading mills have advanced their prices on bars, plates and shapes $1 per ton, making the new quotations on these products $1.15 per hundred pounds f.o.b. Pittsburg. This announcement does not appear to have created much stir, it being generally considered that trade conditions were not responsible, but rather a desire to place the market on a better price basis. Business has however improved a little, and the United States Steel Corporation has increased production to 70 per cent. and blown in two more furnaces, with a third to follow shortly.

Pig Iron.

The Pig Iron market is particularly quiet, and production averages about the same tonnage as during the past few weeks. Prices are being maintained, with no immediate prospect of an advance. Buying is still only for immediate requirements, and consumers are carrying as light stocks as possible.

Machine Tools

Business in machine tools is very quiet, few sales being recorded this week. Consumers are still waiting for an improvement in trade before laying out money on tools.

Metal Markets.

A weaker tendency is noticeable in the metal markets this week, accounted for by reason of reports of unsettled conditions in Europe. Tin is down ½c a pound, and copper 10c a hundred pounds. There is no change in other metals. The demand generally is, if anything, slightly better.

Ottawa, Ont., July 27, 1914.—The trade figures for the twelve months ending April 30, just issued by the Trade and Commerce Department, are very interesting when analyzed. They show that the country cannot be in such a bad way commercially, as trade for the twelve months showed an increase of some twenty-three million dollars. The total trade for the twelve months ending that period was $1,096,883,675, as against $1,079,934,018 for the corresponding period in 1913. The growth of Canada's trade since 1911 has been enormous. For the same period of 1911 the total trade was $757,542,382, or an increase since then of over three hundred million dollars, or more than the total trade a decade ago.

The striking feature of the trade figures is the decrease in our imports and the increase in our exports. The balance of trade, which has been so unfavorable against Canada for fifteen years, is apparently tending to right itself. This balance of trade against Canada has been a continual subject of comment among our political economists. Whether it has been a bad or a good sign is a question for argument, but the ordinary Canadian will be inclined to feel that a condition such as has existed in recent years, where we purchased abroad over $250,000,000 more than we sold, is not altogether as it should be. Whatever the cause, for the twelve months ending April 30 our exports increased by nearly $75,000,000, while our imports decreased $57,000,000. The decrease in imports, of course, accounts for the decline in customs revenue. The decline in imports is evidently largely due to the financial stringency—we are not purchasing so much.

Two reasons are given for the increase in exports. One undoubtedly is the new American Underwood tariff admitting agricultural products. The trade figures also show an enormous increase in the sale of cattle, especially to the United States. In addition, Canadian manufacturers with a restricted market at home, owing to the depression, have very evidently turned abroad. This is shown by the fact that the increase in export of manufactures is no less than $14,000,000.

The imports of metals, minerals and manufactures thereof for the twelve months of 1914 and the corresponding period of 1913 were as follows:—

	1913.	1914.
Brass and mfrs. of	5,357,384	4,271,387
Copper and mfrs. of....	7,666,047	6,351,887
Iron and steel and mfrs. of	139,178,336	114,556,252
Tin and mfrs. of	7,169,767	6,220,244

The exports of metals, minerals and manufactures thereof for the same two periods were:—

Aluminum in bars, blocks, etc.	1,390,180	1,924,758
Asbestos	2,530,294	2,862,577
Copper	9,940,549	9,488,778
Gold-bearing quartz, dust, etc.	11,514,518	13,197,182
Iron and steel and mfrs. of	9,734,474	11,402,544
Nickel	5,010,023	5,459,530
Silver	20,401,660	20,776,093

Winnipeg, July 25, 1914.—Quite a number of educational institutions have been buying machine tools during the past week. The School Board of Edmonton, Alta., have placed an order, amounting to over $1,500, for several lathes to be used in the technical school, the bulk of the order going to the A. R. Williams Machinery Co. Another firm secured an order for an air compressor also from the School Board. The Western Canada College, Calgary, have placed an order with the A. R. Williams Co. for several woodworking machines, while the School Board of Medicine Hat, who are building a technical school, have invited tenders on a complete outfit of machine tools. The A. R. Williams Co. have also supplied tools for a jobbing machine shop at Nokomos, Sask., started by Rankin & Hodson, and an electrically-operated air hammer, of medium capacity, for use in the forge department of the Vulcan Ironworks, Winnipeg.

The Stuart Machinery Co. are selling quite a number of heating boilers in the city, and have recently received an order for two from the Qu'Appelle Sanitarium. They also received an order this week for two motor-driven centrifugal pumps from the C.P.R., to be used at Fort William. They report inquiries for machinery rather light.

The Centrifugal Pump Co., Chicago, are reported to have chosen Winnipeg as the site of a Canadian branch plant. M. T. Chapman, president, and L. W. Bodinson, chief engineer, paid a visit to Winnipeg last week, and their factory, if built here, will employ a hundred men.

Trade Gossip

Canadian Rails—The shipments of steel rails which have come to hand from Sydney, Nova Scotia, and those which are booked for delivery in the near future, are a source of good advertising for Canada, in South Africa, and all the newspapers are giving this item of Canadian export considerable prominence. The rails are being delivered at Durban, as they are all for the Natal main line.

Canada Car and Foundry Co—About a third only of the usual staff of the Canada Car and Foundry Co. is now manufacturing cars and railway equipment. Ordinarily about 1,500 employees are at work at each of the three big plants located at Amherst, Turcot (Montreal), and Dominion (Montreal). At the present time there are less than 1,500 hands employed at all three plants. Present prospects for freight car orders are extremely slim, and the freight department is scarcely operating at all. It was hoped that the Canadian Northern and Grand Trunk Pacific Railroads would require a great deal of rolling stock for immediate delivery; but it now turns out that the former intends to buy only passenger cars at the present time, and the latter to order nothing at all. One of the officials of the company is reported to have stated that they believed the worst was over, and "that the turning point has been reached, and that normal conditions will return by fall." Orders on hand and the recent C.N.R. order ensure satisfactory employment in the passenger car departments till the end of January next. It is rather an unfortunate thing, however, that no freight orders are immediately in sight, as this comprises the great bulk of the company's business.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News.

Engineering

Woodstock, Ont.—The Wayne Oil Tank and Pump Co. will now receive the final payment on their loan from the city, the new factory being completed.

Fenelon Falls, Ont.—The Seymour Power Co. has completed the construction of its new dam near here. The plant is capable of developing about 1,500 horse-power.

Sarnia, Ont.—It is understood that Hon. W. J. Hanna, who is in England at present, is endeavoring to secure for this city the proposed Canadian branch of a large British smelting concern.

Port Arthur, Ont.—The new plant of the Conley Frog & Switch Co. is expected to be completed and in operation by September 1. About thirty men under E. H. Baumgarten are at present employed on the plant.

St. Catherines, Ont.—The first carload of steel for the new factory of Lord & Burnham, Vine Street, arrived recently. More material is expected next week. Work on the construction of the new building is progressing steadily.

Berlin, Ont.—The plant of the Berlin Central Heating Co. has been purchased by a syndicate of Toronto men, headed by C. H. Thompson, who will take charge. It is proposed to double the present equipment and increase the patronage along streets where mains have been laid.

Hamilton, Ont.—The Stanley Works of New Britain, Conn., have decided to locate a Canadian branch here. They have absorbed the Canada Steel Goods Co., and will make large additions to the plant. Among other extensions, they will install a rolling mill. Arthur S. Hatch will be manager of the new concern.

Winnipeg, Man.—M. T. Chapman, president of the American Well Works, Chicago, has been in Winnipeg recently in connection with a proposition to establish a plant in the city. The company manufactures well sinking and drilling machinery, and has recently acquired important patents on pumping machinery.

New Westminster, B.C.—Permission has been given the Heaps Engineering Co. to assign their twenty-year lease of city property to the North-West Trust Co., so that debenture bonds to the amount of $300,000 might be issued in order that the local engineering concern would be enabled to carry out the terms of their original agreement with the city, which was to build a plant on Lulu Island.

Cobourg, Ont.—Mr. Cole was in town from Owen Sound recently with Mr. Hollinrake of the A. R. Williams Machinery Co., Ltd., with a view to promoting a company to operate the Provincial Steel Works here, the plant and machinery of which is now the property of the A. R. Williams Co. It is understood that the town will be asked to guarantee bonds to a certain extent and to grant certain exemptions.

MACHINE TOOL REQUIREMENTS.

The Grand Trunk Pacific Railroad are in the market for the undernoted machine tool equipment for installation at McBride, B.C.:—

One 800-lb steam hammer.
One hydraulic wheel press.
One coach wheel lathe.
One motor-driven driving wheel lathe.
One portable boring bar.
One 36-in. motor-driven planer.
One 30-in. vertical motor-driven drilling machine.
Ore 20-in. vertical motor-driven drilling machine.
One 20-in. motor-driven high-speed engine lathe
One 30-in. motor-driven high-speed engine lathe.
One 20-in. hand planer and jointer.

Further information regarding the foregoing can be had from George W. Cay, purchasing agent, the G.T.P. Railroad, Winnipeg, Man.

New Liskeard, Ont.—The Wabi Iron Works Co. are installing a steel plant in connection with their foundry, and for that purpose they have a building, 35 x 40 feet, in the course of erection. A tilting electric steel furnace will be used, and when this department is in working order the company will be enabled to manufacture all kinds of steel castings, and will more particularly compete for the supplying of shoes and dies used in the concentrators at Cobalt.

Edmonton, Alta.—Sanderson & Porter, of New York and San Francisco, financiers and builders of hydro-electric plants, have submitted a proposal to the city to furnish power from a plant to be erected at Moose River, B.C., in the Yellowhead Pass of the Rocky Mountains, 250 miles west, at prices ranging from one cent. per k.w.h. for the first 50,000,000 to a half cent. per k.w.h. when 120,000,000 is reached. The plant to be installed on a branch of the Fraser River, will cost $3,500,000. Its minimum capacity is placed at 300,000,000 k.w.h., transmitted to Edmonton over cables. The transmission lines will follow the railroad. Stanley Washburn, of Chicago, and G. B. Waesche, one of the company's engineers, who made the surveys, presented the proposal to the council on July 14, when the matter was referred to the Board of Commissioners, headed by Mayor McNamara, for consideration.

Electrical

Galt, Ont.—It is proposed to extend the ornamental street lighting by the addition of standards and lamps.

Dresden, Ont.—By an overwhelming majority, the Hydro-Electric by-law was carried here on July 21. There were but fourteen votes against the measure.

Berlin, Ont.—Steps are being taken by the Light Commission and the Fire and Light Committee of the City Council to instal an up-to-date lighting system for King Street. The members of these municipal bodies visited Brantford and are favorably impressed with the illumination of the main streets of that city, where the Magnetite system has been adopted.

Cornwall, Ont. — The Conservation Commission has directed the chief engineer to make a survey and profile of the St. Regis River from its headquarters to its mouth at the St. Lawrence River, including such lakes, ponds and streams as are tributary to the St. Regis. He is also ordered to make preliminary plans of dams and possible water storage basins, with estimates of the cost thereof, together with a description of existing power developments and census thereof. The power of the St. Regis yet undeveloped is extensive and important.

General Industrial

Tilbury, Ont.—The F. S. Carr Rubber Co. is installing new machinery which will increase the output of their plant.

Preston, Ont.—The Board of Trade are considering a proposition from a company who propose building a factory for making overalls.

Stratford, Ont.—The Mayor has been authorized to sign the final agreement with the company which is to run a motor bus system in this city.

Chatham, Ont.—The Wm. Rennie Co., of Toronto, will erect a large seed warehouse on a two-acre plot located on the industrial spur here. Work is to be started at once.

New Denver, B.C.—The power plant of the New Denver Light & Power Co. was destroyed by fire on July 20. The origin of the fire is unknown, but it may have been caused by lightning.

Winnipeg, Man.—A Cabinet Council has decided to accept the offer of the Grain Growers Grain Co. to renew the lease of the Manitoba Government elevator system for an indefinite period.

Toronto, Ont—The John Warren Real Estate Co. have purchased five acres of land at Wychwood on behalf of a company, which proposes to build a plant for making cement bricks and tiles.

Irma, Alta—The construction work on a new 40,000-bushel elevator to be operated by the Farmers' Co-operative Elevator Co., has been started. The contract has been awarded to F. W. McDougall, of Calgary.

Winnipeg, Man.—Knechtel's furniture factory, on Henry Avenue, was struck by lighting on July 24 during the storm, and as a result $40,000 damage was done to the stock and building. About $19,000 was carried in insurance.

Sydney, N.S.—It is reported that a project is on foot here to establish a factory for the manufacture of overalls, the promoter being the representative of a large overall manufacturing concern in Ontario. It is understood he has selected a site.

St. Catherines, Ont.—The Board of Health on July 21 at a special meeting received a deputation from the Garden City Dairy Co., which proposes to establish a $100,000 plant here to supply consumers with pure milk. The plan was endorsed by the board on resolution.

Ottawa, Ont. — Plans filed at the Marine Department on July 22 provide for increasing the grain elevator capacity of Montreal Harbour Commission to six and a half million bushels. The increase at No. 1 elevator of capacity by 1½ million bushels will cost $800,000.

Port Dover, Ont.—At a recent meeting of the Board of Trade, a committee was appointed to ask the council to submit a by-law to loan the Port Dover Brick and Tile Co. $10,000 for ten years without interest. The company lost everything in the recent fire, and did not carry any insurance.

Walkerton, Ont.—A large section of R. Truax & Son's new factory is now completed, and a number of machines moved from the old structure to the new are installed and in operation. There is still some forty feet of the new building to be erected, and the old factory is being razed to make room for this.

Fort William, Ont.—A party of Pittsburg business men interested in the iron trade arrived here recently and left to investigate and look into the iron deposits in the neighborhood of Savanne, a point on the line of the C.P.R. about seventy-five miles west of Fort William. It is understood the party are working in the interests of the Pickands Mather Co., of Cleveland.

Toronto, Ont.—The Provincial Government has granted to Duncan Chisholm, a local capitalist, a concession to erect a pulp and paper mill at Smooth Rock Falls, on the Metagami River, and to expend $1,750,000 thereon. The daily output of paper will not he less than 150 tons, and the inauguration of the concern means employment for at least 250 hands for ten months of each year.

AUSTRALIA RAILWAY WORKSHOP TENDERS.

Additional tender forms, specifications and drawings for equipment required by the Victorian Government, Australia, railway workshops continue to be received from Commissioner D. H Ross, and are now available for the inspection of Canadian machinery manufacturers at the Department of Trade and Commerce, Ottawa. Particulars of these requirements, together with the dates on which the tenders close at Melbourne, are outlined in the following brief summary:—

27,048—September 9, 1914—725 cast steel wheel centres.

27,049 — September 9, 1914—6,800 cast steel wheel centres.

27,000—September 16, 1914—1,843 tons steel channel bars.

The last mail available to Canadian manufacturers is that which leaves Vancouver on August 5, and is due to arrive in Melbourne on August 30. The contractor must deliver a portion of the service, in each case, within four months from the date of acceptance of his tender.

Personal

R. J. MacKenzie, of the C.N.R., has arrived in Winnipeg on a general trip of inspection.

James Carruthers, president of the Canada Steamship Lines, Ltd., has returned from Bermuda.

Gordon Perry, the general manager of the National Iron Works, Toronto, has returned from Germany.

Sir William Mackenzie sailed from New York on July 23 on the Aquitania for London. He hopes to return about the end of August.

A. M. Nanton, of Winnipeg, has been appointed vice-president of the Winnipeg Electric Railway, to succeed the late Sir William Whyte.

A. Gore, in charge of the Customs Department, Canadian Fairbanks-Morse Co., Toronto, has returned from a six weeks' vacation in Europe.

The Manitoba Bridge and Iron Works, Ltd., Winnipeg, have been awarded the contract for a bridge, to cost $250,000, by the city of Winnipeg.

C. R. Medland, manager of the Winnipeg branch of the General Supply Co. of Canada, Ltd., has returned to the West after a two weeks' visit to Toronto.

Rutledge & Davis have erected a building on Cedar Street, Newmarket, Ont., and have installed an oxygen welding plant. They are prepared to do any kind of repair work.

Archibald Currie, city engineer of Ottawa, has placed his resignation in the hands of Mayor McVeity. Mr. Currie, who came to Ottawa from Westmount, has been incapacitated for some months through illness.

Archibald Blue, chief officer of Census and Statistics for the Dominion of Canada, died somewhat suddenly at his home in Ottawa on July 27. He was a native of Oxford, Ont., and was in the 75th year of his age.

Ralph Modjeska, consulting engineer, Chicago, and a member of the board of engineers of the Quebec Bridge, has been retained by the Burrard Inlet Tunnel and Bridge Co. to report on the tenders which the company has received for the construction of the Second Narrows

"WILLIAMS" MACHINERY LIST

New Machine Tools in Stock

New Engine Lathes.

12 x 6′ R. K. Le Blond.

The A. R. Williams Machinery Co., Ltd., 64-66 Front St. W., Toronto

See how easily they are adjusted

The Thread Chasers with which the Geometric Die Heads are fitted are more easily adjusted and more easily re-ground than any other thread chaser.

Geometric

Screw-Cutting Die Head

Style D

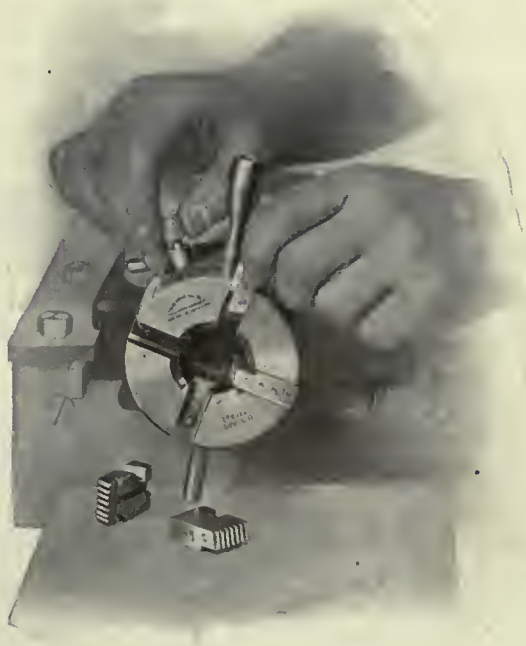
Is designed for use on the turret of hand and automatic screw machines in place of solid dies.

A Big Money-Saver on all Screw-Threading Operations.

Quick and accurate variations may be made in the diameter of the threads for a tight or loose-fitting screw.

The dies cannot move away from the work. Cut threads parallel with the work, requiring no pilot.

Write for Descriptive Booklet.



Method of removing dies or chasers.

The Geometric Tool Company
New Haven, Conn.

Canadian Agents:
Williams & Wilson, Ltd., Montreal. The A. R. Williams Machinery Co., Ltd., Toronto, Winnipeg

Bridge, Vancouver. The structure will cost approximately $2,000,000.

Captain W. E. Holmes, of Victoria, B.C., died on July 13, at Seattle, Wash. Capt. Holmes, who was a well-known navigator on the Northern Pacific, was born in London, England, in 1875.

Rudolf Kauert, manager of the Toronto office of Kauert & Doehler, also dealers in machine tools and supplies, with an office at Montreal, returned from Europe on July 15, after a six weeks trip in England and on the Continent.

Alexander Gibb & Co., Montreal, have been appointed agents in the Province of Quebec for Suter, Hartmann & Rahtjens Composition Co., of London, England manufacturers of anti-corrosive paint and anti-fouling composition.

Thomas Turnbull, formerly connected with the C.N.R., and for the last four years with the C.P.R. and the Hudson's Bay Railroad, has been appointed assistant chief engineer of the Canadian Northern system, with headquarters in Winnipeg.

The Eugene Phillips Electrical Co. are making an extensive addition to their plant in Montreal, to cost in the neighborhood of $150,000. This extension when completed will practically double the capacity of the power and telegraph cable end of their business.

New G.T.P. Directors.—A special meeting of shareholders of the G.T.P. was held in Montreal on July 21, presided over by President E. J. Chamberlin. The following were placed on the board to fill vacancies:—J. E. Dalrymple, F. Scott, W. H. Ardley and H. R. Safford.

W. Grant Morden, of Heatherden Hall, Iver Heath, Bucks, England, and Montreal, Que., has been gazetted honorary lieutenant-colonel of his former regiment, the 6th Duke of Connaught's Royal Canadian Hussars. Mr. Morden's residence in England is in connection with the completion of the plans of the Canada Steamship Lines, Ltd., which he has promoted from the outset.

W. A. Coates, general manager of the Robert Reford Co., was the recipient of a very handsome cigar box from the convention committee of the Canadian Electrical Association, as a token of appreciation of the entertainment extended by him to members and friends of the association on board the Cunard Line Steamship Ascania and the Donaldson Line Steamship Saturnia.

Ernest Belanger, civil engineer and land surveyor, has instituted damage actions of $26,000 and $11,000 respectively against the Montreal Evening News and the Montreal Daily Mail. The actions are the outcome of the opposition of these journals to plaintiff's appointment by the Board of Control as one of the appraisers to value the assets of the Montreal Water & Power Co., the expropriation of which concern by the city has long been discussed. The appointment by the Board of Control was later rescinded by that body, and considerable comment was evoked by the procedure.

Professor John Galbraith, civil engineer, and since 1899 principal of the School of Applied Science at the University of Toronto, died on July 22 at his summer home on Go-Home Bay, in the Georgian Bay district. John Galbraith was born in Montreal on the 5th of September, 1846, the son of the late Thomas and Jane (Anderson) Galbraith. When the School of Practical Science was formed in 1878, he took the chair of engineering. In 1899 he was made principal of the school, and for some years past has been dean of the Faculty of Applied Science and Engineering at Toronto University.

CALL FOR EQUIPMENT.

The Canada Last Co., 5 Van Horne Avenue, Toronto, J. C. Iredale, manager, are in the market for the following special machinery:

Automatic reversible last lathe.
Fibre and leather top grinder.
Thimble press.
Last block saw table.
Scouring machine.
Last trimming machine.

Trade Gossip

The Canadian Fairbanks-Morse Co., Ltd., Toronto, has supplied a complete equipment of transmission machinery with "Skefko" ball-bearings, to the Canadian Seamless Wire Co.'s new plant on Clinton Street, Toronto.

The Canadian Fairbanks-Morse Co. will assume as at August 2 the general sales agency for the well known **Little Giant** line of screw cutting tools and machinery, and will carry stocks of these consisting of taps, dies, screw-plates, bolt cutters, etc., in all their principal branch stores. The **Little Giant** line is manufactured by Wells Bros. Co., of Canada, Ltd., Galt, Ont. (formerly Canadian Tap & Die Co.), and, under the new arrangement, the Canadian Fairbanks Morse Co. also have the exclusive agency for cylindrical and screw thread gauges and automatic opening dies manufactured by the Wells Bros. Co. parent plant in Greenfield, Mass.

George T. Davie, of Geo. T. Davie & Sons, Ltd., Levis, Que., was in Montreal a few days ago on business, and stated that their drydock and shipyard at Levis were unusually busy this season, not only with repair work, but also with the building of new craft. They are now completing two ferry boats. One of these, for the Canada Steamship Lines, will ply between Montreal and Longueuil, while the other, for the Corporation of Three Rivers, will run between that city and Ste. Angele, on the opposite side of the river, to replace the old ferry Glaciale, which was sunk some time ago. The Davie Co. has also just concluded a complete overhauling of two tugs, the Musquash and Gopher, for the Quebec Salving & Wreckage Co.

Toronto, Ont.—The third lighter built by the Polson Iron Works for the Dominion Government for use in Hudson Bay, was successfully launched at the company's yards last Saturday, in the presence of a large and distinguished gathering. The craft, which is 128 feet long over all, 21 feet 6 inches wide, and seven feet in depth when loaded, was christened by Miss Louise Miller. It is expected to have the vessel completed within the next few days, and on its way to the northern waters. Among those present at the launch were: Col. J. B. and Mrs. Miller, Mrs. Lee, Mrs. Miller, mother of Col. Miller; Captain James B. Foote of the Toronto Insurance and Vessel Agency; T. H. Benson, inspector for Lloyds at this port; Harry Miller, Mrs. William Newman, Mrs. B. H. Henderson, and Inspector Crooks of the Department of Railways and Canals.

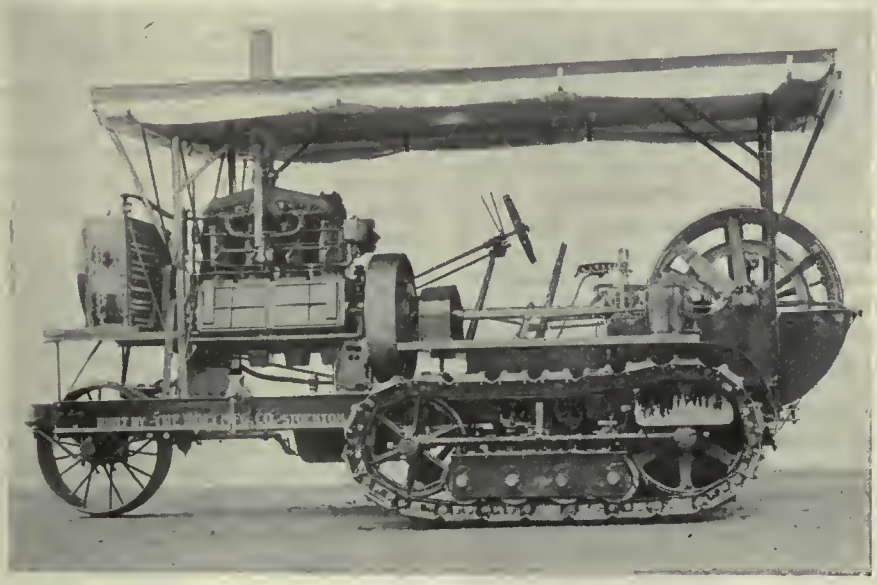
Fraser & Chalmers of Canada, Ltd, Montreal, have received the following orders for "Terry" steam turbines:—One 46 h.p. turbine for driving turbine boiler feed pump, to the order of Escher Wyss & Co., Montreal; one 10 h.p. turbine for driving Lea-Courtenay volute pump for circulating water on compressor air coolers, for the Canadian Mining & Finance Co.; one 17 h.p. turbine for driving Thyssen air pump, and one 45 h.p. turbine for driving a Siemens' exciter set. The two latter turbine orders have been awarded by the Siemens Co., of Canada, the principal contractors. The machinery will be installed by the Britannia Mining and Smelting Co., Britannia Beach, B.C. They have also secured orders for one 20 h.p. turbine for driving a Siemens generator exciter from James Howden & Co., for Alberta University; one 125 h.p. turbine for driving a Lea-Courtenay pump for the town of Charlottetown, P.E.I.

Description of a Gas Tractor Being Built in Canada

Staff Article

The Canadian market for this product of American design and manufacture has assumed such dimensions that a branch office has been opened at Calgary, Alta., and the John Inglis Co., Strachan Avenue, Toronto, are building a number of these tractors to help supply the demand.

ON the large wheat farms in Alberta and the Canadian West it has been felt that the general use of machinery was nothing less than an absolute necessity. The difficulty of obtaining sufficient and competent help during the harvest season has always been a source of worry to the Western farmer. Then, again, as wheat fields are being pushed farther and farther north, the early frosts become a greater menace. Thus, the importance of getting the seed grain in the ground at an early date. With these facts in view, the large steam tractors were designed, and these machines were a great success, in as far as their ability to accomplish their work was concerned, their only drawback being that of obtaining fuel. Water and coal are scarce commodities on the Western Prairies.



CATERPILLAR TYPE GAS TRACTOR, MANUFACTURED IN THE UNITED STATES BY THE HOLT MFG. CO., STOCKTON, CALIFORNIA, AND IN CANADA BY THE JOHN INGLIS CO., TORONTO, ONT.

Appreciating these difficulties which beset the farmer, the engineers of the Holt Manufacturing Co. of Stockton, California, have designed and built a tractor of the internal combustion type. The liquid fuel is much more easily obtainable than coal and, although the engine is water cooled, the amount of water evaporated from the cooling system in a day of ten hours averages about one gallon. The fuel used generally in this machine is **Distillate**, which is cheap and easily obtainable. Thus, it would appear, that the difficulty of obtaining fuel for such machines is greatly lessened.

General Observations.

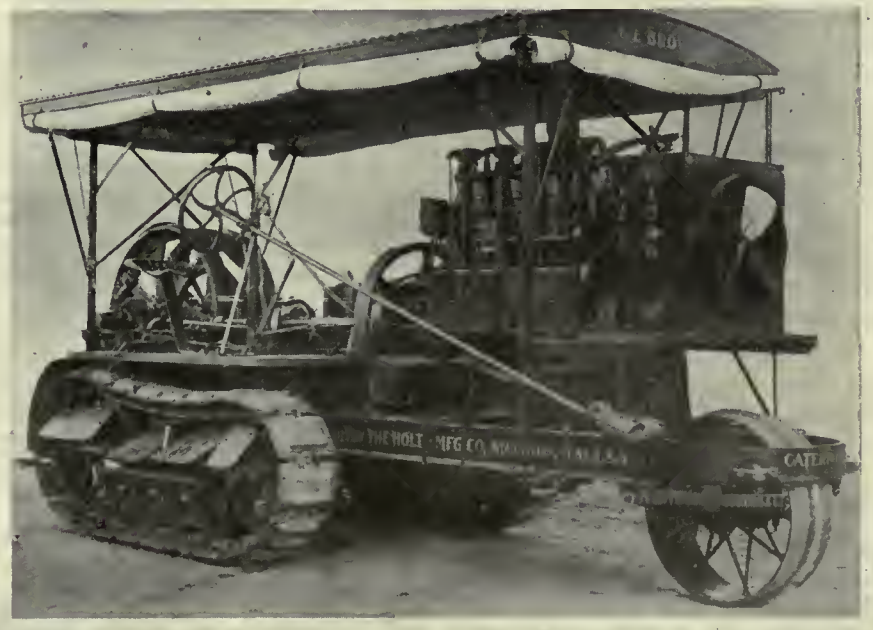
The tractor is driven by two caterpillar type drivers, which support the whole weight of the machine, except that which the single wheel at the front carries. This wheel is very wide, as also are the drivers, and in spite of the fact that the machine weighs nearly ten tons, the pressure on the ground per square inch is not greater than that under a man's foot. The tractor, it is claimed, can very easily go over the softest kind of ground.

The commonest use of the machine is for early spring plowing, and on average ground it will plow twenty furrows at once, running at a speed a little over two miles per hour. There are, of course, many other uses to which the tractor can be put, among them being that of a stationary engine. The clutches transmitting the power to the tractors can be thrown out and the entire power be transmitted to a pulley mounted on the frame of the engine.

The Motive Power.

The power plant of the machine is a four-cylinder, four-cycle, internal combustion engine, with cylinders 7 in. bore and a stroke of 8 in. The cylinder heads are cast separately and bolted. Both the intake and exhaust valves are in these heads. The cylinders are also cast separately, and are bolted to a cast iron crank case.

The crank shaft is supported by five main bearings, and in the sides of the crank case are four large hand hole covers, and so large are these hand holes that the main bearings, cam shaft bearings, oil pump and connecting rods are readily accessible. In fact, the pistons



CATERPILLAR TYPE GAS TRACTOR MANUFACTURED IN THE UNITED STATES BY THE HOLT MFG. CO., STOCKTON, CALIFORNIA, AND IN CANADA BY THE JOHN INGLIS CO., TORONTO, ONT.

and connecting rods can be removed from the engine through the hand holes.

A Splitdorf Magneto is mounted on the cam shaft side of the motor, and to make starting easy, a set of batteries and a Splitdorf coil are also connected to the system. The spark plugs are located on the side of the cylinders, while the spark control lever is situated just above the steering wheel.

Lubrication.

The lubricating system is efficient, yet at the same time not complicated. There is a main oil sump in the bottom of the crank case, from which a gear pump discharges the oil through four sight feeds to four oil wells located one under each connecting rod. A small overflow carries the surplus oil from each well back to the main oil sump. In this way the oil in the four wells is always at a constant level, and the connecting rods dip the proper amount under all conditions of operation. The main oil sump will hold about seven gallons of cylinder oil. The splash oils the connecting rods, main bearings and the cam shaft bearings. There is also an auxiliary oiling system which consists of a McCord oiler. In this mechanism is a small plunger pump driven by a little coil spring belt. This pump forces oil through four copper tubes to the wrist pins and cylinder walls.

The Fuel Feature.

The full tank is located in the frame of the machine, and the fuel is pumped from this tank to a well near the carburetor, the overflow returning to the tank. The carburetor takes its fuel from this well. It is a single jet, 1¾ in. Schebler make. The intake manifold is so arranged that each cylinder has to suck its mixture the same distance.

The throttle valve lever is located beside the spark control lever above the steering wheel, and the engine develops its rated power at a speed of 650 r.p.m. A simple governor is attached to the motor, which throttles it when its speed becomes greater than 650 r.p.m. The air intake of the carburetor is so arranged that, if desired, air can be used directly from the atmosphere, or warm air can be taken from a chamber surrounding the exhaust pipe.

The Cooling System.

The cooling system is highly efficient. A tank located in the frame of the tractor is capable of holding sixty gallons of water, and a belt-driven centrifugal pump delivers water to the water jackets in the cylinders, and thence through a sight feed to a spring-mounted radiator and back to the tank under the tractor. In front of the radiator a fan is located, which forces cool air through it. To make the system capable of accommodating itself to the slight flexibility of the steel frame many lengths of rubber hose are inserted in the pipe lines.

Operating Conveniences

The driver's seat and the steering wheel are located on the right side of the machine, while the spark and throttle levers are directly above the steering wheel. In the flywheel at the rear of the engine is located the main clutch. This is of the disk type, and is operated by a hand lever immediately to the left of the driver's seat. Each of the caterpillar tractors has a separate clutch, the operating levers of which are also located to the left of the driver's seat. The reversing device is operated by two levers located also to the left of the driver's seat, but a little more toward the rear.

The Power Transmission.

The power is transmitted from the crank shaft to the flywheel, thence through the clutch to the crank shaft extension shaft, on the rear of which is located a steel bevel pinion with thirteen cut teeth 3½ in. face, 1.46 diametral pitch. This pinion meshes into either of two steel bevel gears of 106 teeth. These gears are mounted on a countershaft. Two sprockets of seven teeth each are keyed to this shaft, and are connected up by chains to two sprockets of twenty teeth, each keyed to the platform wheel rear shaft. This shaft drives the tractor. The two bevel gears on the countershaft comprise the reversing apparatus. When the pinion meshes into the left-hand gear, the tractor goes ahead, and it reverses when meshing into the right-hand gear. A universal joint takes care of the slight amount the crank shaft extension is out of alignment when reversing.

Manoeuvring Features.

By means of the two independent clutches for the caterpillar tractors the machine is able to turn in a very small space. The single wheel in the front, of course, is the main steering link. The weight carried by this wheel is not excessive, and is supported by a roller thrust bearing, being thereby quite easily operated by the steering wheel. As the motion is transmitted through a worm, it is irreversible, and the steering is very simple. The front wheel can be removed, and all the weight will be taken by the tractors. Thus the machine can cross ditches and holes with comparative ease.

The Caterpillar Tractors

The caterpillar tractors are very ingenious devices. There are three shafts, i.e., platform wheel rear shaft, platform wheel centre shaft, and platform wheel front shaft. The first of these three shafts carries the driving sprockets, and thus propels the tractor. The centre shaft supports the entire weight of the machine, while the principal duty of the front shaft is to keep the caterpillar tractors in their proper place and shape. The distance between centres of the rear and front shafts can be quiet easily adjusted so as to keep the tractor link in its proper place. This tractor link consists of a chain which, on the back of each link, has a drop forged steel cap riveted. These steel caps are about 15 in. wide, and are so arranged that they closely overlap one another, whether they are flat or are on the sheaves. There are sprockets on the platform wheel rear shaft which engage in the chain, and thus transmit the power to the caterpillars.

There is a small truck mounted on each end of the platform wheel shaft centre, and on each truck are four rollers—two above and two below, which deliver the weight of the machine to the tractors. These trucks are mounted on springs, and on that account lend a great deal of flexibility to the tractors. Large and cumbersome obstacles can be run over without sudden jar or jolt to the mechanism. On the platform wheel shaft front, two rollers are mounted, which simply guide the chain and keep the tractors in alignment.

Miscellaneous Details.

The chain in the tractors is naturally strong. The pins are steel, case-hardened, 1¼ in. diameter, and work in manganese steel brushes. The various links in this part of the mechanism are oiled automatically from an oil tank on the platform of the machine. The shoes in the tractor are made so that little or no earth is allowed to get into the working parts.

The whole machine is in itself a very complete unit. The engine develops about 75 brake horse-power on the pulley used for stationary work, and, running to full capacity, the engine consumes about 65 gallons of distillate in a day or ten hours. The distillate retails in Canada at something less than ten cents a gallon. Two men only are required to operate one of these foregoing tractors.

The Turbine Equipment Co., Ltd., Toronto, has recently obtained the following orders from the Cobalt Lake Mining Co., Ltd.:—One 12-in. De Laval centrifugal pump, having a capacity of 5,000,000 gallons per day, and one 6-in. De Laval centrifugal pump, having a capacity of 875,000 gallons a day; both will be driven by induction motors.

PRODUCTION METHODS AND DEVICES

A Department for the Interchange and Distribution of Shop and Office Data and Ideas Evolved from Actual Practical Application and Experience

TURRET LATHE AND VERTICAL BORING MILL PRACTICE.—II.*

By Albert A. Dowd.

THE introductory portion of this article dealt with the first setting and sequence of operations in machining the rear hub of an automobile on a vertical turret lathe. In the present instance, the second setting and sequence of operations are dealt with in detail.

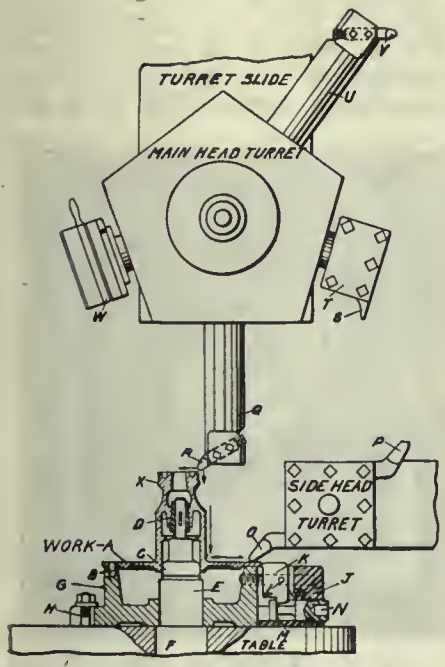


FIG. 3. LAYOUT OF TOOLS FOR SECOND SETTING OF WORK, A.

Second Setting Of The Work.

Figure 3 shows the layout of the tools for the second setting of the work A. A cast iron fixture G is centered in the table hole by the stud F and it is held in position on the table by means of the tee-bolts H. A tool steel pin B is used as a driver in one of the flange holes. The portion E of the stud fits the fixture body and extends upward to form the cylindrical locating surface C, which fits the bearing seat in the work. A taper sleeve D is hardened and ground to a sliding fit on the upper portion of the stud, and it is forced upward into the taper seat by the coil spring below it. It will be seen that this construction gives very accurate locations, the compensating action of the taper sleeve equalizing any slight variation which may take place between the face of the flange and the taper.

In order to guard against uplift of the work during the process of machining, the swinging clamps K are thrown into engagement with the edge of the flange by means of the shouldered operating screw M. Provision is made at N for a socket wrench. It will be noted that due to the position of the pin L on which the clamp swings its action is downward and inward, thereby tending to hold the work down on its seat firmly. The blocks J in which the clamping mechanisms are located are of steel and are fastened to the fixture by means of screws. These blocks are placed 120 degrees apart around the outside of the fixture. The reason that these blocks are not integral with the fixture body is that they may be more easily machined if formed up separately and afterward attached. The special turning bar Q is of .040 carbon steel and is provided with a high speed tool R, and it will be noted that the tool extends below the end of the bar, and that it is provided with a backing up screw for fine adjustment. Attention is also called to the shape of the tool, this being such that it may be used to cut in two directions, horizontally and vertically. A nicking tool S of high speed steel is held in a standard tool holder T in the turret hole. The bar U in the next hole is of identical construction with the one previously described, and the tool V is used for finish turning and facing. An opening die head W completes the turret tooling.

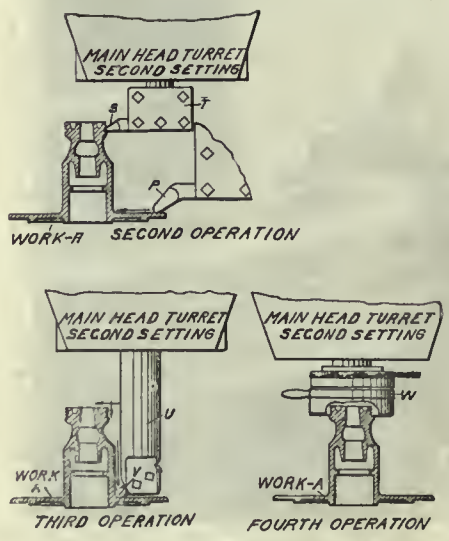

FIG. 4. FOURTH OPERATION—SECOND SETTING.

Two tools O and P in the side head are used respectively for roughing and finishing. They are both forged from high speed steel.

Sequence of Operations—Second Setting.

The tools shown in the working position in Fig. 3 are used for the first operation on the piece, the bar Q being used to face the end of the hub, rough turn the thread diameter, and turn the straight portion of the hub. The tool O in the side head faces the back of the flange while the other operation is taking place.

Second operation:—The second operation consists of nicking the threaded portion of the hub, the tool S being used for this purpose. The side head tool P is started on the finish facing of the flange as soon as the nicking has been accomplished with the mainhead. A very coarse feed and a light cut is used for the finish facing, which is therefore completed in about the time taken to index the turret for the next operation.

Third operation:—The turning tool V in the bar U is now brought into play to face the end of the hub, turn the thread diameter, and finish turn the straight portion of the hub. Coarse feeds are also used for this finishing, so that the time required is very short. The side head is not used in this operation.

Fourth operation:—The threading of the hub is accomplished by means of an opening die shown at W in the illustration of the fourth operation. In using a die head of this sort on the vertical turret lathe, the turret is brought down to a fixed point which allows the chasers to start on the work. The head now travels downward, generating the thread as it proceeds until a predetermined point is reached at which the opening mechanism operates. The use of a die head of this sort saves much time in the operation and precludes the necessity of reversing the machine as might be found necessary if a solid die head were used. This operation completes the piece.

A NEW LATHE CARRIER.

By H. Womersley.

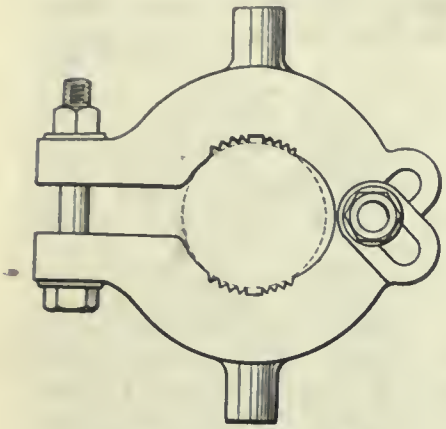
ALONG with the continuous development of lathe pulling power, there has been noted the failure of many of the ordinary lathe carriers or dogs. The illustration shows one that has successfully met the severest requirements of our shop and, for other reasons, has won more or less popularity among the men.

The body is made of steel and the serrated grips are hardened. The device, being made in two pieces, can readily be replaced or removed without taking

*Part I. of this series appeared in last issue.

the work off the centers, a useful feature for heavy work.

The capacity of this type of driver is fairly high. One size can be made to take from 2 to 4 inches, another will take work from 3 to 6 inches, and a third will accommodate from 5 to 9 inch diameters. If the dogs be made for special sizes of shaft, they will be found to be particularly light, strong and compact, considering the hard service to which they can be put.



A NEW LATHE CARRIER.

TURNTABLE FOR HORIZONTAL BORING MILL.

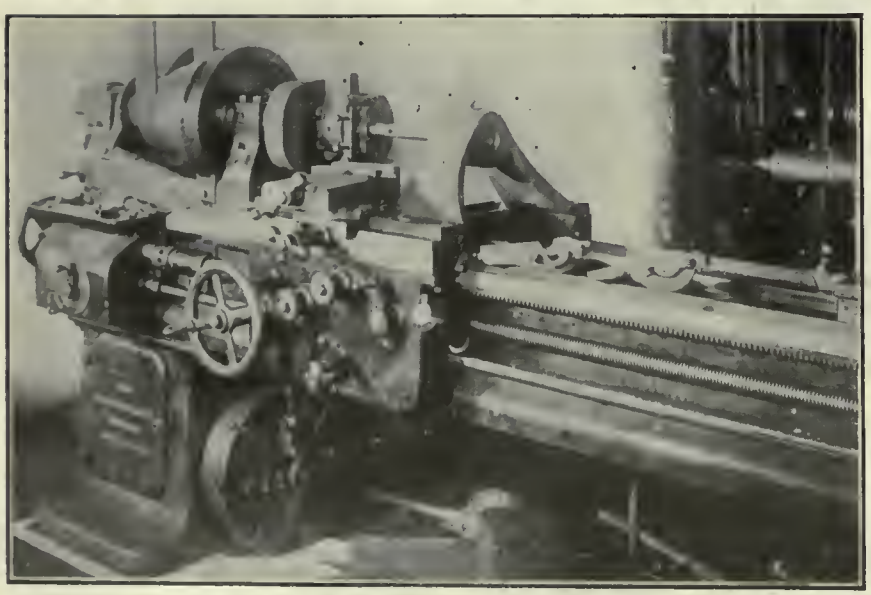
By C. I. B.

THE horizontal boring, milling and driling machine shown in the accompanying photo was used mainly for milling and boring two-cylinder opposed gas engine beds and gas tractor parts such as axle housings, gear cases, etc. This was the busiest machine in the shop and at one time a similar machine of another make was purchased to assist, but was later thrown out due to light construction.

The machine shown is of the floor type with sliding vertical column. A great amount of time was lost in the setting up of certain jobs and especially in re-locating after each operation. Much of the work was symmetrical with respect to center lines, and so it was decided to enlarge the scope and capacity of the machine by the addition of a turntable. The table itself was 52 inches in diameter and remained on the machine as a permanent fixture, as it was possible to use the rotating table on nearly all the jobs. The four clamps were placed beneath the table proper which was carried on a separate base casting bolted to the main machine table, and which carried the index pin. The index pin is operated by the lever shown at the front, the pin having teeth milled on the one side. A long bar was used for turning the table, this being inserted in bushed holes in the edge.

In order to locate the boring spindle centrally over the table for the various operations, this position was first determined, and then a large taper dowel pin was put through the base of the column and into the base proper on which the column slid. A stop was placed at the top of the vertical column and gauges of the various lengths placed between this stop and the top of the sliding head for locating vertical distances. It was thus an easy matter to locate the spindle position for any boring operation after previous milling. For boring, the regular outboard bearing was used, being placed just outside the turntable on the regular machine table. The outboard bearing for the boring bar in the view shown was located directly on the turntable in order to bring it as close to the work as possible, the table not being indexed for this particular job. This casting was used for the axle housing of a gas tractor and was faced on both ends and bored for roller bearings.

It will be found that the addition of a table of this sort will very greatly increase capacity of a machine of this style and, in fact, a plain milling machine as well. There is hardly a job on which milling and boring is done that cannot be turned around to some extent, thereby saving another setting-up.



TURNTABLE FOR HORIZONTAL BORING MILL.

A GRAVITY CLOCK

By D. O. Barrett.

THE clock shown in the accompanying photo is called by its owner, an old gentleman living in the City of Mansfield, Ohio, a **Gravity Clock**, being only one step removed from perpetual motion. The clock has been viewed by numerous parties, and various conjectures advanced as to the method of operating. The minute hand of the clock may be removed and placed upon a pin of the proper size in any position, and it will immediately come back to the position corresponding to the proper minute, and its movement will then be in synchronism with that of the minute hand of a clock. This is often demonstrated by painting the hours on a door or wall and placing the hand in a nail in the centre. The hands are at present supported upon a bicycle spoke attached to the back of the glass frame, and have absolutely no connection whatever either with the pivot or the case.

A GRAVITY CLOCK.

The small piece hanging vertically contains the proper gears for operating the hour hand, and the actuating mechanism is contained in the enlargement at the end of the minute hand. A small weight is moved about in such a manner that the balance of the arm is disturbed and the actuating force is, therefore, in reality gravity.

THE COLLEGE GRADUATE.—II.*

D. S. Mann.

INITIATIVE is a quality which is almost entirely overlooked in the average college man's education, and it is only after he has been knocked around on the wave of competition that he realizes that this side of his character needs development. The man who leaves college with the desire to go ahead and with the quality of stick-to-itiveness is a find indeed, and the man who feels that he is not above taking a situation or even a job beside those who have not been as fortunate as he in the matter of education should, without any trouble, rise head and shoulders above his fellow workers. If he does not, then he should feel that something is wrong, or that there is no chance of advancement in that particular place and should move on to where opportunities are brighter, but he should first satisfy himself that the fault is not his own.

Recognizing Opportunity.

Does the average college man recognize opportunity when it appears before him? Many of them are so egotistic and have such a puffed-up-idea of their own importance (or at least of their superiority over the working man without the college education) that opportunity means to them a sudden rise to heads of departments, managers, and various other exalted positions with large salaries. They seem to imagine that opportunity is trailing along on a leading string which they have only to pull. Others, again, are so meek and unassuming that they do not realize their own merits and look upon opportunity with fear and trembling, and are afraid to grasp the hand which it extends. It is said that opportunity comes at least once to every man, but in the writer's opinion it comes several times a year to most men, and with some it is continuous, but is always sent away empty-handed. The average college graduate feels that what is offered is beneath him or that the road to success is too long.

The writer has often noted that where many men are employed and things are not going just as they should, there is always quite a discussion as to who will get certain executive positions as soon as changes are made, but how many of these same men do we find striving for something better, who are fitting themselves for that particular position in case there should be a vacancy.

As an example, an instance occurred recently in a shop in which several college men are employed—men who have been out of college from one to three years. This shop had rather an elaborate system of shop management, commonly known to-day as scientific management, and these men were employed in various departments, such as drafting room, stock keeping, stock room, planning, etc.

Two changes in department heads were made, one in the drafting room, and one in the machine shop. Both of these had been common topics of conversation for some time because of the inefficient manner in which they had been operated, but it seemed never to have occurred to any of these men that there was any possibility of their obtaining either of the positions. When the time came to choose a new chief draftsman, it was necessary to pass up our college friends and pick out a young man scarcely more than an apprentice, but who thoroughly understood some of the details of the work which had been passed up by the others as relatively unimportant. In deciding upon a machine shop foreman, a fine toothcomb was applied in efforts to obtain a suitable man; but not a man could be found to whom the work could be entrusted, yet all had been quite busy discussing how soon the occupant would lose his job.

This would have been a golden opportunity for some of our college friends, and would have yielded them experience for which they had been waiting for years in vain. The opportunity came, knocked, and not only was refused admittance, but was kicked out, and how often do we hear the cry that department heads are not picked from men in the shop, but rather that outside men are invited in. Is it any wonder that such conditions exist?

Instruction In Dealing With Men.

Our colleges do not seem to impress upon students the qualifications necessary for the successful holding of various positions which they will, in all probability, be expected to fill. In order to handle men, one must study men, must bring himself to understand them and be able to put himself in sympathy with them, and, perhaps the most important of all, he must understand just what a good day's work is and be able to appreciate the difficulties and the stumbling stones encountered by the man himself.

The only way in which this can be properly brought about is by actual contact with both the men and the work. Would it not be more profitable, then, to put in a course of lectures on this most instructive subject in our colleges rather than try to impress upon the minds of engineering students the elements of logic and other abstruse subjects?

*Part 1. appeared on July 30.

CONFERENCES OF DEPARTMENTAL HEADS.

By P. W. Blair.

IN all manufacturing establishments the idea of regular periodical conferences of the heads of the various departments is one that is rapidly gaining in popularity.

A large manufacturing concern in Ontario who have adopted this idea, hold meetings on the first Monday in every month, under the direction of the president. The men attending consist of those in charge of the office staff, receiving department and stock rooms, the order routing clerk and the various foremen. The practical adoption of many proposed schemes is discussed, and their relative effects examined before trying out, so as not to upset the shop routine uselessly. Of course, many valuable ideas are discovered and put into practice, while in addition, healthy criticism is made of the company's policy. Thus, quite often the efficiency of the plant is increased and the production cost lowered.

It has been shown in one or two instances that the appointment of committees to investigate situations is a very excellent way to obviate the initiation of many costly practices. The members of these committees pride themselves on their appointment, and strive earnestly to adjust matters to the mutual advantage of the firm and the employees.

Moreover, foremen learn to respect the interests of other foremen, and the company becomes a large co-operative unit. The machine shop learns how to accomplish their work so that the assembling department will experience the least trouble at their end. Likewise the moulder studies the needs of the machine shop, and the draughting and designing departments study the needs of the whole plant.

The conference idea seems to stimulate the departmental heads to work to greater efficiency, and the management as a result operates to vastly better advantage, and can, therefore, be more liberal with its employees.

Series of Practical Questions and Answers for Mechanics

Every care is being taken to include only pertinent practical questions, and give same direct, reliable answers. Catch questions will be avoided. Attention is drawn to the alternating course in arithmetic, a concurrent study of which is recommended with that of the Question and Answer Series.

RELATING TO BEAMS.

IN the previous problems in which this subject was involved it was endeavored to give solutions for problems concerning simple beams likely to be met with by the average foreman and operator. An effort was also made to show the relation of beams to revolving shafts and how the same fundamental formula could be applied in both cases. By understanding this formula the strength of beams and shafting can be calculated, no matter what the material of which they are made, providing that the shearing, compressive, and tensile strength of this material be known.

The valnes given by handbooks are usually those of the ultimate strengths per square inch, or for any material, is the load sufficient to part a bar 1 inch square. To get the working load, it is necessary to apply a factor of safety. For dead loads, such as buildings, this is usually not less than 4; for varying loads, such as bridges, from 4 to 6; and for loads varying from maximum in one direction to maximum in the other direction, or in the form of shocks, the safety factor ranges from 6 to 10, according to judgment of the engineer. This means that it would require from 4 to 6 times the working load of a new bridge to break it down.

So far we have dealt with problems in which the beams were either uniformly loaded or were subjected to single loads acting at the central point. The effect of the loading is simply to change the value of M, the maximum bending moment, in the formula $\frac{M}{S} = \frac{I}{c}$. For a central concentrated load, $M = \frac{Pl}{4}$ where P is the total load in pounds and l the length of the span in inches. For a uniformly distributed load, $M = \frac{Pl}{8}$. Thus it is seen that a beam will sustain twice as much uniformly distributed load as concentrated load. The bending tendency of the load subjects the beam to compression on the upper side and tension on the lower side, hence whichever happens to be the weaker value should be used. The weight of the load tends to shear the beam or break it apart. The shearing action is greatest at the supports, and consequently is equal to the loads on the supports.

Question—A beam has a span of 50 inches and is loaded at three points as follows:—1,200 lbs. at 12 inches from the right hand end, 1,400 lbs. at 24 inches from the same end, and 2,600 lbs. at a point 18 inches from the other end. Find the loads on each support.

Answer—The load on either support is equal to the sum of each load multiplied by its distance to the other support, divided by the total length of the span. The reaction of the right hand support would therefore be

$$\frac{1200 \times 38 + 1400 \times 26 + 2600 \times 18}{50}$$

=2,576 pounds.

2.576 pounds.

The weight on the left support would be

$$\frac{2600 \times 32 + 1400 \times 24 + 1200 \times 12}{50}$$

=2624 pounds.

This could also be found by subtracting the load on the right hand support from the total load, or 5,200 — 2,576 = 2,624 pounds ans.

• • •

—**Question**—In the above problem, determine the bending moments (M) at the three points.

Answer—The bending moment at the 1,200 lb. load would be the reaction of the right support multiplied by the distance of the 1,200 lb. load from the right hand end, or = 12 × 2576 = 30,912 inch pounds.

The bending moment at the 1,400-pound load is the right hand reaction multiplied by the distance of the right hand support from the load minus the 1,200 pound load multiplied by the distance between the two loads. Thus, 2,576 × 24—(24—12) × 1200 = 2576 × 24—12 × 1200 = 618.24—14400 = 47424 inch lbs.

In the same way the bending moment at the 2,600 lb. load is 2576 × 32—1200 × 32 + 1400 × 8 = 83432—38400—11200=34832 inch pounds.

The greatest bending moment is at the middle load, and is therefore the moment used as the value of M in calculating the size of beam.

• • •

Question—A horizontal tubular boiler weighing 18,000 pounds is hung from two I beams in such a way that the weight is equally divided between them. The span of the beams is 8 feet and the points of support of the boiler are 4 feet apart, 2 feet either side of the center. What size I beams would be suitable?

Answer—Formula, $\frac{M}{S} = \frac{I}{c}$.

M is greatest at either point of loading and is the same at both. M is therefore the load on one support multiplied by the distance from the support to the nearest load, or is $\frac{18000}{4} \times 24 = 4500 \times 24 = 108{,}000$ inch pounds.

Using a safety factor of 4, S becomes 15,000, substituting values in formula, $\frac{108000}{15000} = \frac{I}{c}$, or $\frac{I}{c} = 7.2$. Now, looking in the handbook we find for 6-inch beams at 12.25 lbs. per foot I = 21.8; c for 6-inch beam $= \frac{6}{2} = 3$; $\frac{21.8}{3} = 7.27$; 7.2 only is required, therefore the 6-inch 12.25 pound beam would be sufficient.

• • •

Question—A 10-inch I beam at 30 pounds per foot is loaded in the center between supports 12 inches apart. Would it fail by shearing or bending?

Answer—The moment of inertia for this beam is 134.2 and its cross sectional area is 8.82 sq. in.

S = 60,000 pounds per sq. in. $M = \frac{Pl}{4}$; $c = \frac{10}{2} = 5$.

Formula $= \frac{M}{S} = \frac{I}{c}$, $\frac{Pl}{4S} = \frac{I}{c}$, or $P = \frac{I}{c} \times \frac{4S}{l}$, $P = \frac{134.2}{5} \times \frac{4 \times 60000}{12} =$ 536,800 pounds.

Shearing strength of steel = 50,000 pounds per sq. in. Area of this section is 8.82 sq. in.

Load necessary to shear it is then 50,000 × 8.82 = 441,000 pounds. The piece would, therefore, fail by shearing. Beams of any considerable length fail by bending.

• • •

Question—A number of I beams are to be placed to project 6 feet from the wall of a building and at right angles to it for the purpose of hoisting a 7-ton piece of machinery to an upper floor. What combination of beams could be used?

Answer—Formula, $\frac{M}{S} = \frac{I}{c}$.

$M = 7 \times 2000 \times 6 \times 12 = 1{,}008{,}000$ inch pounds.

$S = \frac{60{,}000}{5} = 12{,}000$ lbs. per sq. in.

$\frac{M}{S} = \frac{1{,}008{,}000}{12{,}000} = 84 = \frac{I}{c}$.

Using 2 beams $\frac{I}{c}$ for each would be $\frac{84}{2} = 42$.

From the handbook we find I for the heaviest 12-inch I beam = 245.9 and c = 6.

This gives $\frac{I}{c} = 41$, a little too low; but as we use a safety factor of 5, two 12-inch beams at 40 pounds per foot would do the work. If we used three beams, the $\frac{I}{c}$ for each would be $\frac{84}{3} = 28$.

I for a 10-inch 30-pound beam is 134.2; $c = 5$; $\frac{I}{c} = \frac{134.2}{5} = 26.8$, which is too low.

For a 10-inch 35-pound beam I = 146.4

$\frac{I}{c} = \frac{146.4}{5} = 29.3$, which is a little large. Therefore, three 10-inch 35-pound beams would do. In the same way it will be found that four 9-inch 30-pound beams will do the work.

J. H. Williams & Co. Employees' Welfare Assn.

For some time past this firm have been developing a plan whereby they could make available to their employees' pensions, life insurance and vacation allowances. Announcement of the completed scheme was recently made, and further that it went into operation on July 1. Each employee was given a neat little folder, setting forth in detail the various provisions and conditions.

THE J. H. Williams Co., of Brooklyn and Buffalo, N.Y., has since its inauguration always been to the front in looking after its employees welfare, and this latest idea is one which clearly represents the character of those at the head of the institution. The benefits outlined in this recent announcement are to be distributed through a committee known as The J. H. Williams & Co. Employees Welfare Committee. This will consist of five members, two of whom will be appointed by the company. These, in turn, will appoint a third, who must be a shop employee, while two others will be named by the J. H. Williams & Co. Mutual Aid Association. This welfare committee is to be chosen every two years; the present company will, however, only hold office until Dec. 31, 1915. Every other December, beginning with 1915, a new committee will be appointed.

The Pension Feature.

Those men who are eligible for pensions are such as have reached the age of 65 and have been for 25 years continuously in the service of the company. The company also reserves the right to retire any man on a pension after he has reached the age of 55. In the forge, blacksmith, polishing and case-hardening departments an employee may be retired at the age of 60 after serving the company for twenty years. This retirement at 60 years after twenty years service also applies to any female employee of the company. Further, any employee with not less than 15 years' continuous service, whatever his or her age, claiming to be unfitted by reason of permanent physical or mental disability from following his or her employment in the Company's service, may be retired at the discretion of the welfare committee.

In computing the period of service, it is reckoned from the date since which the person has been continuously and exclusively in the service of the company to the date when retired. Temporary lay-off on account of reduction in the company's force, or absence on account of illness, or dismissal, if followed by reinstatement within one year, shall not be considered as a break in the continuity of service, but if for any reason absence exceeds six months, such length of absence shall be deducted in computing the length of service.

The amount of pension is computed on the following basis:—For each year of active service, one per cent. of the average annual pay during the ten years next preceding retirement. However, at the discretion of the Welfare Committee, this may be altered, in such cases as they see fit, to read "one per cent. of the annual pay of the ten consecutive years of service during which the retired employee was paid the highest rate of wages." The minimum monthly pension in no case shall be less than $15, and the maximum monthly pension not greater than $100. Reasonable restrictions are attached to the system so that an employee cannot abuse these privileges. Also, reasonable measures are taken to protect the company, and pensions may be increased, reduced, or forfeited, according to the discretion of the Welfare Committee, which must be guided by regulations set forth by the company.

The Insurance Feature.

The insurance policy of the company is also of a most generous nature. Every employee who has been in the continuous employ of the company for three years is entitled to benefit by the insurance scheme. Any employee who has been in the continuous service of the company for three years, and less than ten years, shall be insured for six months' wages, while those who have served over ten years will be insured for one years' wages. The continuity of service is computed similarly to that of the pension method. How the insurance is paid, and to whom, is clearly outlined, and conditions which would lead to the forfeiture of the insurance benefits are also definitely stated, so that it is difficult to imagine that any controversy could arise.

Vacation Allowances.

The system of vacation allowances is also very liberal. It simply states that any shop man, who on May 1 of each year shall have been in the service of the company continuously for at least two years and whose record of attendance and faithful discharge of his duties during the twelve months of each year ending with the first Wednesday in May, shall have been satisfactory to the foreman of his department, will receive a vacation allowance of one-half week's pay. If, however, his service shall have extended over a period of five years or more an allowance of one week's pay will be made.

The company expects to close its shops for the first week in July each year, but should it be desired to have the shops working during that week, a vacation at another period may be given. Further, if business conditions are such that no vacation can be taken, the company reserves the right to keep its shops working and to give the equivalent allowances to its employees. The company intimates, and it must be so understood by its employees. that this welfare system can be maintained only during the profitable operation of its business.

The whole plan is highly praiseworthy and might be profitably emulated by many other concerns, as its action is sure to bring the employer and employee together in a common interest.

PROGRESS IN NEW EQUIPMENT

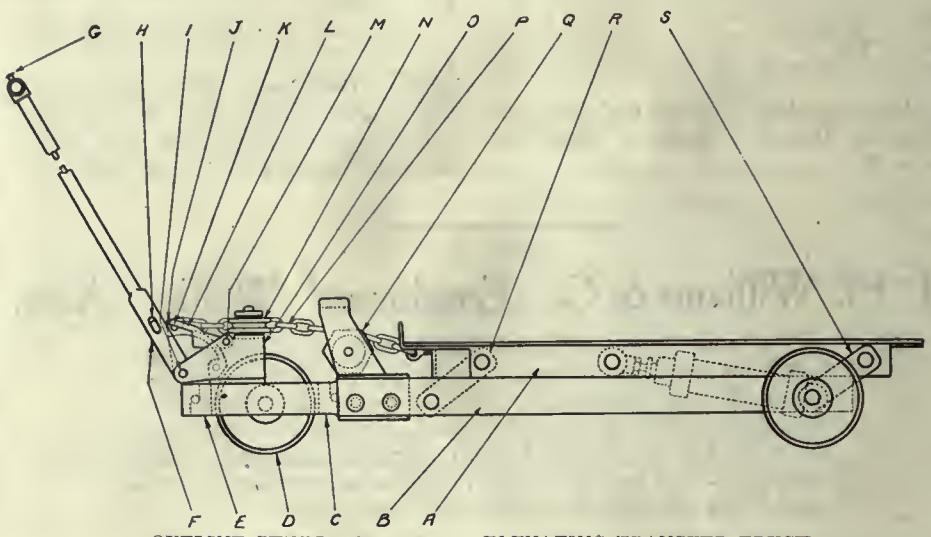
A Record of New and Improved Machinery and Accessories for the Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

A SIMPLE ELEVATING TRANSFER TRUCK.

THE problem of materially reducing manufacturing costs without impairing the quality of the finished product is one that constantly engages the attention of every live manufacturer to-day. Wonderful developments in machinery steel, high-speed tool steel, and improved designing have all tended toward an ever-increasing efficiency. Thus, while improvements along these scientific lines were being developed, some of the simpler ideas have been lost sight of. So it happens when one runs across some simple yet important development, in other than scientific spheres, it is, to say the least, highly refreshing.

Of such a nature is the new elevating transfer truck that the Chapman Double Ball Bearing Co., of Toronto, are about to place on the market. This truck is of one-ton capacity, with a lift of two inches. The entire control is in the steering handle, which, being made from ¾-inch standard pipe, is hollow.

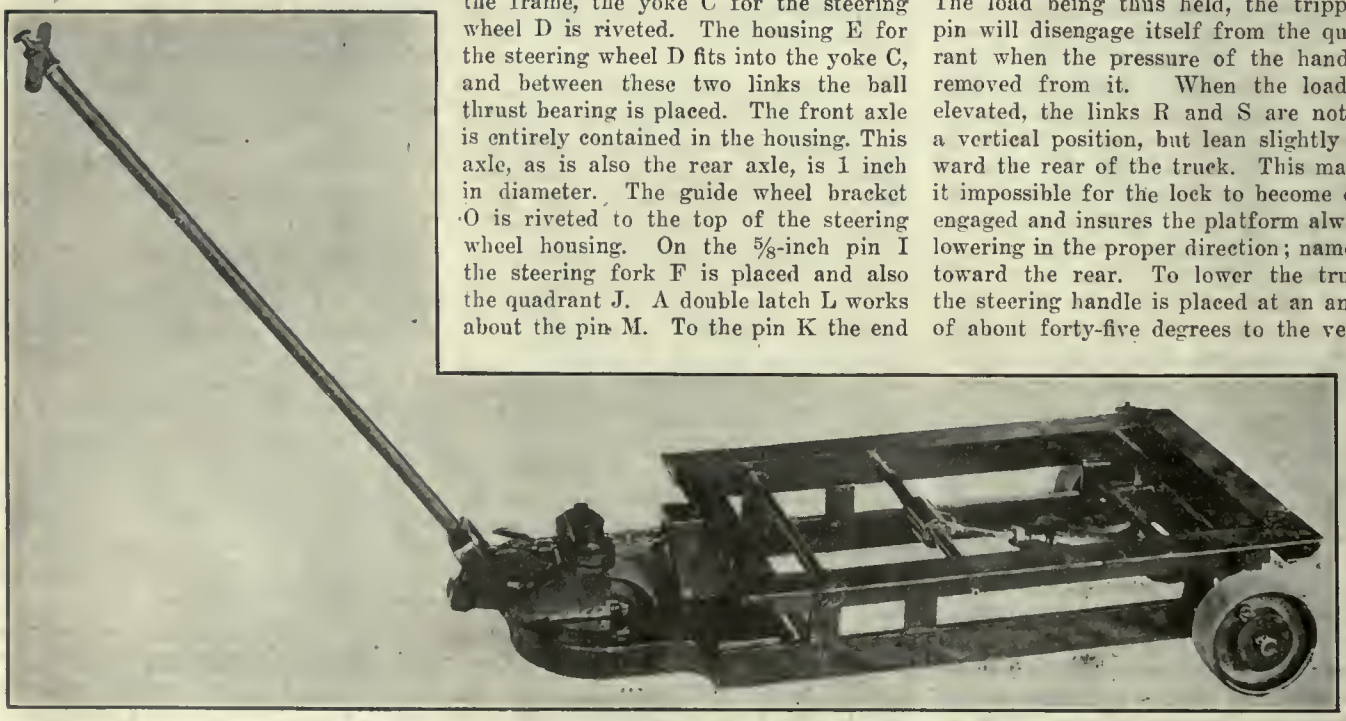
The principal feature of this truck is that it may be operated when the steering handle is turned in any direction. It is mounted on three 7-inch wheels of 2½-inch face, each wheel being equipped with a double ball bearing. In addition to these, there is also a ball thrust bearing in the steering wheel housing, thereby making the truck very easy to turn when loaded. To start to lift the full load of one ton from the floor, it requires something less than a pull of 125 pounds. As soon as the load is started, the pull required rapidly diminishes.



OUTLINE SKETCH OF SIMPLE ELEVATING TRANSFER TRUCK.

The over-all length of the truck is 53 inches and the width 24 inches. The platform A is 36 in. x 24 in., and the frame B is made from a bar of machinery steel ⅝ in. x 2½ in., bent in the shape of a U. In the open end of the frame, the yoke C for the steering wheel D is riveted. The housing E for the steering wheel D fits into the yoke C, and between these two links the ball thrust bearing is placed. The front axle is entirely contained in the housing. This axle, as is also the rear axle, is 1 inch in diameter. The guide wheel bracket O is riveted to the top of the steering wheel housing. On the ⅝-inch pin I the steering fork F is placed and also the quadrant J. A double latch L works about the pin M. To the pin K the end link of the chain P is attached. This chain passes between the two sheaves N in a horizontal plane, and on over the vertical sheave Q to the platform A.

To elevate a load, the steering handle is placed in a vertical position and the button G is pressed, engaging a tripping pin H with the quadrant J. By lowering the steering handle toward a horizontal position, the load is lifted from the floor. When off the floor two inches, the latch L engages with a locking pin. The load being thus held, the tripping pin will disengage itself from the quadrant when the pressure of the hand is removed from it. When the load is elevated, the links R and S are not in a vertical position, but lean slightly toward the rear of the truck. This makes it impossible for the lock to become disengaged and insures the platform always lowering in the proper direction; namely, toward the rear. To lower the truck, the steering handle is placed at an angle of about forty-five degrees to the verti-



NEW ELEVATING TRANSFER TRUCK OF ONE TON CAPACITY.

cal, the button G is pressed, and the steering handle pushed up to a vertical position. As a hydraulic check is fitted

VIEW OF ELEVATING TRANSFER TRUCK LOADED.

to the truck, the load quickly, yet gently, lowers itself to the floor. The elevating and lowering operations can be executed when the steering handle is in any direction. This is made possible by the two horizontal sheaves N which cause the pull of the chain to be properly directed when the steering handle is turned out of line with the truck.

The platform is constructed from steel angles 2½ in. x 2½ in. x ¼ in., and its covers are securely bound together by steel straps. Small steel guides are riveted to the frame, and these cause the platform to ascend and descend in a manner such that it will never bind and cause undue friction and wear. Pieces are also riveted on the truck platform of such shape as to guide it under the portable wooden platforms. Stops are also provided to prevent the truck from passing too far under these wooden platforms.

The truck is substantially built throughout, and all the working parts are simple and not likely to get out of order. The fact that the truck can be operated from the steering handle entirely, and also when that handle is turned in any direction, is a distinctive feature and greatly increases its field of usefulness.

E. G. Buckwell, secretary of the Cleveland Twist Drill Co., Cleveland, left for Europe on a business trip August 1st.

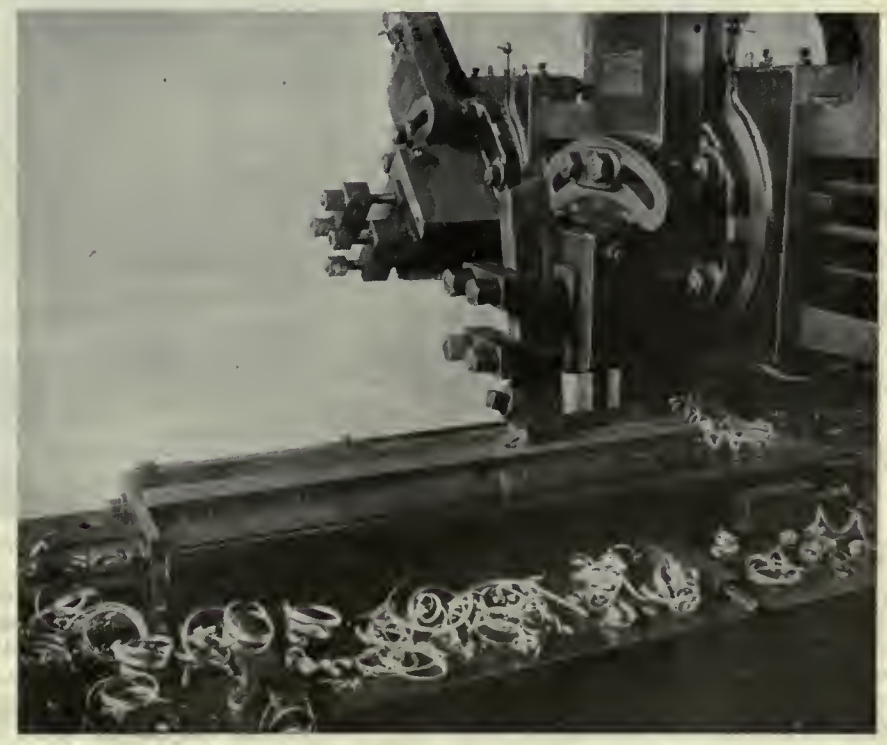
NEW MAGNETIC CHUCK.

THE use of magnetic chucks for holding work to be machined has very much increased of late years. This is due to a number of contributory causes chief of which are the improvements in the chucks themselves. The convenience of chucks in which all labor of clamping and fastening has been done away with can hardly be overestimated particularly for flat and fragile work. Besides this, the magnetic chuck has opened up a large field for itself in work considered practically impossible by the ordinary means.

The time occupied in setting up work occupies from one to seventy per cent. of the total time on the job. Some pieces also require to be specially designed to provide means of fastening in the machines in which they are to be worked up. When the elaborate outfit required for other work is taken into consideration, it can easily be seen that many plants could afford a fairly expensive device to eliminate this work and expense.

The illustration shows the coil arrangement of the new Heald magnetic chuch for planing, milling and grinding machines. The holding power of these chucks has been greatly improved, being 112 lbs. per sq. in. from actual test. This, of course, could be varied if desired by decreasing the current. Uniformity of holding power has also been greatly increased, the maximum variation between any two poles being 5 per cent. The shallow arrangement of the coils as well as their concentration has practically removed the magnetism from the body of the chuck, a very objectionable feature of the earlier types. A very desirable feature is that the chuck may he entirely demagnetized when the current is turned off. This the Heald people claim to have accomplished to such an extent that it can be guaranteed.

The water proofing and non-heating qualities of these machines have made them available for a very wide range of work, making possible the use of any of the cutting and grinding compounds. The unit coil system used makes electrical repairs extremely simple and inexpensive, and the small consumption of



"HEALD" 10 IN. X 32 IN. FLAT MAGNETIC CHUCK ON PLANER WORK TAKING A CHIP 5-16 IN. DEEP WITH A 5-32 IN. FEED, AND WORK SPEED OF 60 FT. PER MINUTE ON MACHINE STEEL.

energy is remarkable when the holding power of the device is considered.

The top plates are made thick enough to allow of truing up several times and when worn out can be easily replaced. Attention is particularly called by the makers to a planing job done on one of their regular chucks. This consisted of a cut 5-16 in. deep with a feed of 5-32 in. at a working speed of 60 ft. per minute on mild steel. The magnetic holding power was sufficient to prevent any tendency of the work to rise throughout the whole job. The above developments have been worked out by the Heald Machine Co. of Worcester, Mass., who manufacture both round and rectangular chucks in various sizes.

THE ZOELLY STEAM TURBINE.

IN 1898 Mr. Zoelly designed a new type of steam turbine which resembled in many respects a water turbine of the impulse type. This machine was designed on the radial flow principle, the blades not being curved. A second machine with curved blades, however, gave better results, the steam in this case striking against the rotor blades in radial direction. The principle of the impulse type has been adopted as being the best, and the only alterations that took place were in the manner of guiding the steam onto the wheels. The Zoelly turbine has gone through many stages of improvement which, however, have been solely of a constructional character, no departure from the adopted principle having taken place.

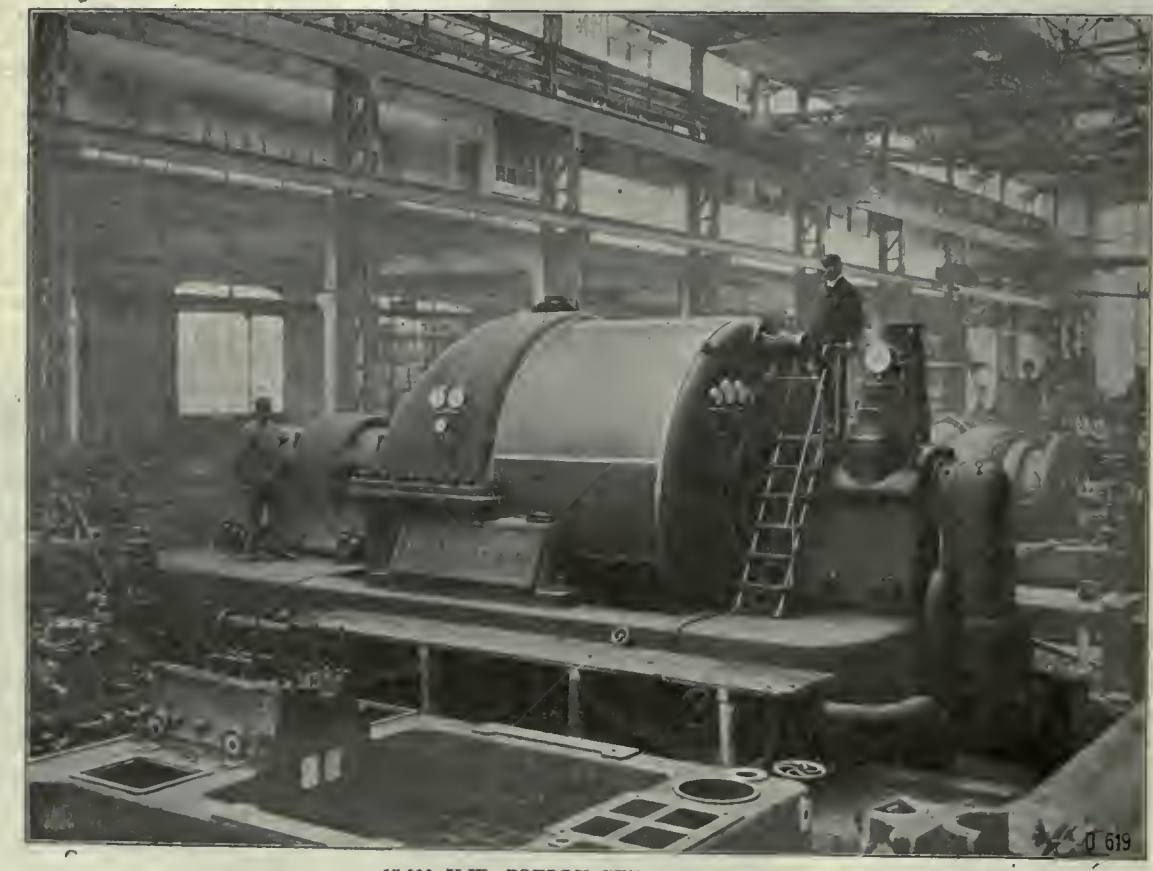
The Zoelly turbine has, in the past, been subjected to a good deal of criticism respecting the steam pressure and temperature in the first stage which were considered to be excessively high and were supposed to have a deleterious effect upon the stuffing boxes. In the case of the present Zoelly machine these criticisms are without foundation as in the first stage a greater pressure drop and likewise a correspondingly higher steam velocity is made use of than previously. This velocity equals or even surpasses that of sound corresponding to the steam conditions of this particular stage.

In order to be able to construct large units without having to employ too large blades in the last two stages, these stages are provided with a greater drop of pressure, so that they also work with steam velocities which may be 5 and even more per cent. higher than the velocity of sound. The intermediate pressure stages work with steam velocities which do not or only in a very slight degree exceed the velocity of sound belonging to the conditions of these stages. At any rate, the excess of velocity over that of sound is in the intermediate stages never so great as in the first and last stages.

The total drop of pressure available has been divided up in such manner that it has been possible to reduce the number of stages and thereby shorten the turbine by an appreciable amount. If necessary, these stages are constructed with expanded guide channels or nozzles. This expansion is not, however, designed for full load, but only part load, i.e., about half or a quarter of full load, in order to insure a good efficiency even at part full load. Such types of Zoelly have been built since the year 1908. The characteristic feature of the Zoelly turbine has always been the design of the runner wheels and guide channels in the diaphragm, the former of which in spite of the high factor of safety required, are enabled to give a relatively high circumferential velocity. Consequently greater latitude is permissible in regard to the number of stages and speed of the steam in each case.

Construction of the Zoelly Turbine.

The Zoelly turbine has from the commencement always been constructed with a horizontal shaft; experience with water turbines having shown that by this method the simplest form of bearing can be used, permitting an easy inspection at all times. In the case of turbines running at 3,600 revolutions per minute a flexible shaft is used, so that the critical speed is sufficiently below the working speed; but in the case of turbines running at 1,800 revolutions per minute and under, the contrary is the case, the shaft



15,000 K.W. ZOELLY STEAM TURBINE.

is rigid and the critical speed is above the working speed. The shaft is supported by two bearings which are lubricated by oil under pressure, and is connected by means of a rigid or flexible coupling (usually rigid) to the generator or machine to be driven. The casing is built up in two halves, the joint being horizontal, so that the rotor can easily be inspected without dismantling the bearings. An idea of the accessibility of all the important parts can be gained from the illustration shown.

The impulse type allows large clearances in radial and axial direction. The axial clearances of the runner blades as well as the radial clearances are about 2 inches., nevertheless, the steam consumptions obtained with the Zoelly turbine is claimed to be lower than that of any other make, particularly for the large size high speed units. It is what can best be called a commerial machine, that is a machine giving, with the greatest reliability, best economy and least wear, with a minimum of attendance required. The total thermodynamical efficiency obtained has been as high as 74 per cent.

Twenty firms are at present licencees of the Escher Wyss Co., of Zurich, who built the first machines and have since supplied the bulk of those put on the market.

Up to 1913, Zoelly turbines of 3,350,000 horse power have been supplied by the Zoelly Syndicate. of which those built by Escher Wyss & Co., had a capacity of over 800,000 horse power. The largest size machine was 15,000 k.w.. equal to 28,000 horse power. Two of these units were supplied to the Rheinisch-Westfaelisches Elektrizitaetswerk (Germany)—one in 1911, and the second as a repeat order in 1913. A number of machines of similar size have been built for other concerns, a plant of four 10,000 k.w. units for the Chile Exploration Co., of New York, being a pertinent example.

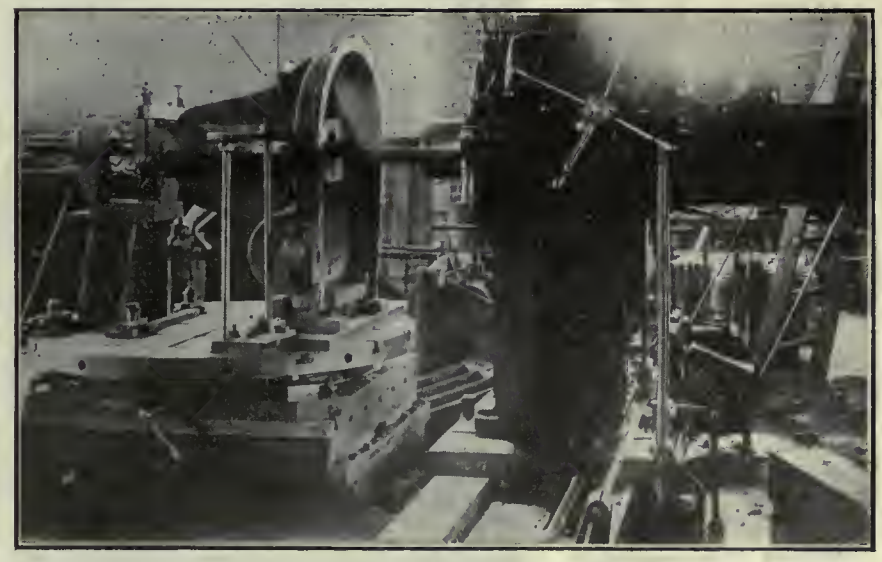
IMPROVING THE ENGINE LATHE

By D. O. Barrett.

IN these days of competition it is highly important that each manufacturer keep as nearly as possible all of his tools working at the very maximum, and while it is not always possible, and sometimes, perhaps, not desirable, to have the very latest type of machine tools suitable for the work, for various reasons peculiar to each manufacturer, it is highly desirable that the tool producing a certain class of work shall do so at the minimum cost as regards the capital invested, the labor expended, upkeep and depreciation. Of course, in the lathe field, the turret lathe for the greater majority of jobs is acknowledged to hold supremacy, yet in a good many cases the old, despised engine lathe will often produce results not obtainable by even the best of turret lathes.

For certain classes of work the engine lathe is without a peer. The main difficulty for the man in charge is to so assign the work that both the turret and the engine lathe may operate most advantageously. In many instances it is possible for one turret lathe to serve as a feeder for several engine lathes; that is, the second or third operation upon certain pieces may be done upon less expensive machines, as well as by less expensive help, also being done somewhat quicker in point of time, thus effecting a double saving. Again, the amount of money invested in a first-class turret lathe is, in many cases, sufficient to install three or four engine lathes.

The purpose of this article is to show a method devised by the writer for improving the engine lathes under his supervision. In this case he was not fortunate enough to have any kind of a turret lathe at all, and consequently the desire was to make the engine lathe perform as nearly as possible all the adjuncts of the turret lathe, and the labor and expense involved were amply justified by the results obtained. In this particular shop there were several engine lathes of practically the same capacity, and the only difficulty was in refraining from overloading these machines.



IMPROVING THE ENGINE LATHE.

The cut shows the style of cast iron bridge which was mounted across the back of the carriage and took the place of the turret. This bridge was dowelled on each side of the carriage back of the tool slide, and the hole for holding the boring bars was bored by means of a bar between the lathe centres, so that it came in exact alignment with the lathe spindle; the bridges on the different lathes were bored the same size, so that the tools of any one lathe could operate, if necessary, on any other. The bars were held in position by means of a shoulder on the bar, slightly larger than the bored hole.

In the cut, in which a cam box for a gasoline engine is shown, the bar was slotted and the boring tools held in place by means of a wedge at the front, these being removed and replaced again at each operation. A bushing was provided in the holding fixture for guiding the bars at the outer end. After the hole was bored the carriage was run back until the bar came entirely out of the case, when a reamer was slipped on the tapered end and then fed through by hand. For facing, the ordinary cross slide was used, but this does not show in the cut, as the tool was removed to get a better view of the method of holding the piece. It was not necessary to remove the tool post at each operation, as the cross slide could be run back out of the way when boring.

In this particular case there is, of course, one disadvantage to this method which cannot be overcome, and that is that facing and boring cannot be done simultaneously; but in the shop where a turret lathe is at hand this work would probably not be done on this machine.

The cost of these bridges and tools is in most cases very insignificant in comparison with the results which can be obtained, and the writer would recommend this method to anyone who desires to further increase the field of usefulness of the engine lathe.

The Canadian Westinghouse Co., Ltd., Hamilton, has opened an office and warehouse in Fort William, Ont., with B. James, of Hamilton, in charge.

THE VALUE OF A WORKMAN.

A SHORT time ago the American firm of Niles-Bement Pond Co. were awarded a contract involving some millions of dollars for the equipment of new arsenals in China. Although other considerations than the amount of the bid, such as time, quality and capacity of the machinery involved, were large factors in bringing the work to this aggressive firm, the whole transaction furnishes some food for thought on the part of all patriotic citizens of Canada and the United States.

This business was secured in the face of the keenest competition of Britain, Germany and other great manufacturing countries who specialize in this kind of work. Machinists and tool makers of Belgium are said to receive less than one dollar per day, while the corresponding employees on the American continent receive as much as four dollars for the same period of work. Taking into account the recognized fact that the American workman is the highest paid artisan in the world, it would seem that under certain conditions at least, the size of the wages paid in the process of manufacture does not materially affect the cost of the product.

It can hardly, however, be fairly assumed that the American mechanic can do at least four times as much work as his foreign competitor, even though he obtain about this proportion of results. The greater part of this achievement must be charged to other factors than physical stamina and endurance. There exists in America as in no other land, a condition of free competition among employees as well as employers. This rivalry is without ill-will, and is towards the attainment of methods of reducing labor and bettering working conditions as well as to obtaining a greater amount and better quality of the product.

The manufacturers encourage this by rewarding the more productive employees with increased pay and promotions in positions, and even though the remuneration is often complained of, the American workman, more than any other, is paid in proportion to his accomplishments. The employers have shown considerable daring in making the goods and creating the market for them afterwards, and results have shown that, just as sure as the condition of the demand affects production, so production will set up a demand.

By far the greatest element in the enlargement of the scope of our workmen is the universal spread of broad and practical education. America is the home of the correspondence school, the cheap technical journal and the greatest attainments in university education. The application of trained mechanics' brains and unhindered personal effort to the production of the necessities and comforts of life have enabled the workman of this continent to produce, in comparison with all others, the most for his employer, to be of the greatest value to his country and to obtain the most out of life for himself.

ROOM FOR IMPROVEMENT IN THE FOUNDRY.

IN nearly all branches of the mechanical trades a very large part of the gray matter has been devoted to reducing, if not practically eliminating, the physical and mental effort required of the operatives. This has ,particularly in some branches of the machinists line, resulted in practically making it a sedentary occupation, and what so-called skilled labor is left, is not calculated to severely tax the brawn of the mechanic. In the pattern shop, the addition of the universal saw, jointing and grinding machine is working towards the same end, the stool or chair now being a necessary part of the patternmaker's equipment. In the foundry alone the progress of mechanical improvement is having the reverse effect, if any.

A number of companies have put forth creditable efforts in the direction of making life easier for the moulder but much remains to be done in this direction. The cutting of the sand by machinery and feeding it to the moulds from overhead hoppers; the transference of the moulds to a pouring floor to be poured by a separate crew of men, and the extended provision of improved lifting and handling machinery have been inaugurated completely or in part by a number of progressive firms. The improvement of conditions in the foundry, heretofore more or less neglected, requires and is worthy of the best brains of mechanical engineers.

INDUSTRIAL NOTABILITIES--No. 46

HON. GEORGE A. CLARE, M.P., was born at Preston, Ont., June 6, 1854, of German descent, the son of John and Marguerite (Beck) Clare. He was educated at Preston Public School and started in his father's stove business in 1875. With his brother Frederick, and Henry C. Hilborn, he acquired the business in 1881, and operated under the name of Clare Bros. & Co., being later incorporated under the present name in 1901.

In matters commercial, Hon. George A. Clare is president, Clare Bros. & Co., manufacturers of stoves and furnaces, Preston, Ont.; president Galt Stove & Furnace Co., Galt, Ont.; president Clare & Brockest, Winnipeg, Man., manufacturers of stoves and furnaces; president Canadian Office and School Furniture Co., Preston; president Solid Leather Shoe Co., Preston; director Preston Car & Coach Co., Preston; director

HON. GEORGE A. CLARE, M.P.

Stamped & Enamelware, Hespeler, Ont.; and director Wellington Mutual Fire Insurance Co., Guelph, Ont.

He was councillor of Preston for two years; Reeve ten years; first mayor in 1900, when Preston was incorporated a town; member County Council of Waterloo, 1888-1898; warden County of Waterloo in 1895; elected Member of House of Commons, 1900; re-elected, 1904, 1908 and 1911, and appointed Member Privy Council of Canada, Jan. 1st, 1913.

He married Catherine Fink, daughter of Paul Fink, Waterloo, on April 19, 1876, there being one son and three daughters of the union.

In religion, Hon. G. A. Clare is a Lutheran, while his club life embraces the Albany, Toronto; Waterloo, Waterloo; Waterloo County Golf and Country; Galt, Galt; and Deutscher Verein, Toronto. His residence is at Preston, Ont.—Photo, courtesy the International Press.

The General Market Conditions and Tendencies

This section sets forth the views and observations of men qualified to judge the outlook and with whom we are in close touch through provincial correspondents.

Montreal, Que., August 3, 1914.—The prevailing dullness of the last few weeks in machinery circles still continues. The European crisis seems to have overshadowed the optimistic outlook, and business is now at a complete stand still. Prospective buyers hesitate to close any deals, and a general anxiety is very evident; all cables from the seat of the trouble being received with feverish interest. For the past week, however, small orders have been continuing to pour into the machinery supply houses. This business serves the purpose of keeping their organizations intact, although representing but a small turnover.

The intense gravity of the situation seems to impress everyone. To what extent the Canadian and American markets and commerce will be affected is a matter of conjecture, and the outlook seems to be generally far from bright. Banks have practically ceased to advance money on even the best of security, and business is thus additionally crippled. Nevertheless, as far as the month of July is concerned the returns issued by the civic building department show that the number of permits granted totaled 354, valued at $2,521,520, an increase of nearly a million dollars over the permits issued in the same month last year. The figures for July, 1913, were 352 permits, valued at $1,555,665. The reason for the increase was that there were issued permits for three churches and for the large Loyola College that is to be erected in Notre Dame de Grace.

Dealers in steel and iron, who aim to supply largely European products, and on account of the uncertainty of receiving further shipments, prefer rather to conserve their stock and await developments. On account of the low prices of this class material all dealers have a pretty large stock on hand, and feel certain that they can supply all demands for some time to come. However, should it become necessary, these goods can be imported from the United States.

Metals.

The metal market is also very dull. Little or no change in prices has occurred, and all orders are of the hand-to-mouth variety. A fair advance in the price of tin is about the only change of note in the price list.

On August 1 the London Metal Exchange was closed until further notice.

Toronto, Ont., August 4, 1914.—It is impossible to form any definite opinion as to what will be the effect on business in Canada of the international complications in Europe. The extent of the effect will depend upon the length to which the powers concerned will go in prosecuting their respective causes. It is unthinkable that such a calamity as a general European war should become an accomplished fact, but the situation is very grave and signs are not wanting this will happen. Even if better counsels prevail and peace reigns once more, the effect already produced will leave its mark on business conditions for some time. Great difficulty will be experienced in obtaining funds for financing new works, as banks will be obliged to conserve their resources to the utmost. The improvement in trade which we were beginning to enjoy will receive a serious set-back, and it is highly probable that construction work of any magnitude will be stopped until the trouble has subsided and confidence is restored in financial circles.

The crop reports are not quite so satisfactory, and indications are that about an average crop will be gathered this year. If the war continues, better prices will be obtained, which will offet to some

extent the disappointment occasioned by the reduction in yield.

The Steel Market.

No change of any importance is noticeable in the iron and steel markets as yet, although the outlook of hostilities in Europe is bound to have a serious effect on the steel trade here. It is difficult to say how serious the situation really is, but it will no doubt call a halt to any large expenditures as railway ex- to any large expenditures, such as railway extensions and on public works.

European war news has not yet affected the steel trade in the United States except in the rise in price of some imported products, such as galvanized sheets, etc. An effect will no doubt be felt on account of the increased difficulty in financing. Up to the present time a slight improvement in the situation had been noticeable, July proving practically as good a month as June both as regards tonnages booked and production. The United States Steel Corporation statement for the June quarter shows a falling off in earnings of 50 per cent. over the corresponding quarter last year, but an improvement over the first quarter of this year.

Pig Iron

The pig iron market is dull, and does not show any indication of improvement. Reports from the United States indicate that the pig iron market generally is quiet, although in some districts better conditions prevail. Prices continue stationary.

Machine Tools.

The demand for machine tools is quiet, and shows no tangible improvement. In view of events in Europe it is highly probable that the demand will fall off still further, and the market become quieter than it has been for months.

Metal Markets.

The European crisis is affecting the metal market, and a general slowing up in business is noticeable. Prices are fairly steady, with the exception of tin, which has taken a big jump, having advanced 20 cents a pound, with the prospect of a further rise. The New York Metal Exchange will reopen to-day after being closed for several days.

Personal

T. R. Perkins, assistant manager of Toronto branch of the Pedlar People, Ltd., has been appointed manager of the Winnipeg office.

A. F. Hatch, formerly president of the Canada Steel Goods Company, of Hamilton, Ont., has been appointed general manager and treasurer of the Hamilton branch of the Steel Goods Company, of New Britain, Conn., the latter company having absorbed the former. Operations will be commenced without delay on the erection in Hamilton of an extensive new plant.

Captain Alex. Cameron died on July 22, at Owen Sound, Ont., at the age of 84. Captain Cameron was born in Scotland and came to Canada at the age of 7.

Trade Gossip

The Eberhard & Wood Mfg. Co., have purchased two Wright & Wood motors from the Dominion Machinery Co., Toronto.

The Turbine Equipment Co., Ltd., Toronto, has recently obtained an order from the J. W. Danforth Company for two De Laval 125 h.p. steam turbine-driven centrifugal pumps.

The Crescent Machine Co., Ltd., 20 Longueuil Lane, Montreal, are going to manufacture the "Warner" silent tumbling barrel, described in Canadian Machinery issue of July 16 as a product of the Warner Bros. Co., Bridgeport, Conn.

The Refrigeration & Engineering Co., of Winnipeg, have been awarded a contract for a Campbell oil engine by the town of Shoal Lake, Man. The Canadian General Electric Co., Toronto, was awarded a contract for the electrical equipment.

Mussens, Ltd., Montreal, have received an order to equip the shop of the Cook Construction Co., of Halifax, N.S., with a complete line of machine tools, including lathes, planers, drills, and pipe machines. The Cook Construction Co. is engaged in the extensive improvements now being made to Halifax harbor.

Representation Discontinued.—We are advised that the arrangement whereby the Canadian Fairbanks-Morse Co. have been exclusive agents in Canada for the Niles, Bement, Pond Co. ,and their Canadian subsidiary, the John Bertram & Sons Co., Dundas, Ont., has been discontinued as at August 1. The Canadian Fairbanks-Morse Co. will continue to represent the product of the R. McDougal Co., Galt, Ont., as also the Brown & Sharpe line of milling machines, grinders, screw machines. Arrangements have further been made with William Seller & Co., Philadelphia, who for many years have been manufacturers of railroad machinery, etc. In lieu of the representation of the Pratt & Whitney line of small tools, which was also discontinued at August 1, the following lines will be carried by the Canadian Fairbanks-Morse Co.:—Cleveland twist drills and reamers, Brown & Sharpe milling cutters, and Wells Bros., of Canada, Ltd., taps and dies.

Tenders

Ottawa, Ont.—Tenders will be received until Monday, August 31, 1914, for the construction of harbor improvements, being a wharf and approach at the foot of Wentworth street, in the City of Hamilton. Plans and forms of contract can be seen and specification and forms of tender obtained at the Department of Public Works and at the offices of the District Engineers, Confederation Life Building, Toronto, Ont.; Windsor, Ont., and on application to the Postmaster at Hamilton, Ont. Blue prints can be obtained at the Department of Public Works by depositing an accepted bank cheque for the sum of $20, made payable to the order of the Honorable the Minister of Public Works, which will be returned if the intending bidder submit a regular bid. R. C. Desrochers, secretary.

Toronto, Ont.—Tenders will be received up to Monday, October 5th, 1914, for constructing across the Don Valley a bridge consisting of five steel arch spans, with piers and approaches, the width being eighty-six feet and the length, approximately, sixteen hundred and eighteen feet. Bidders may obtain specifications, including plans and form of tender, on application to the Commissioner of Works, Toronto, after paying to the Commissioner of Works, $25 for each set, this sum to be refunded upon return of plans. The engineer's estimate of quantities will also be sent on request. Specifications, including plans, may be seen at the offices of the Commissioner of Works, Toronto; the Commercial Intelligence Department of the Board of Trade, London, England. Those desiring to submit tenders on reinforced concrete construction for the above bridge are hereby notified that they may prepare and submit, without any expense whatsoever to the city, their own plans and specifications, based on the loading given in the specifications for steel construction, and may tender on the same. These tenders will be received up to noon on Monday, October 5th, 1914.

Refrigeration

Regina, Sask.—The buildings and plant of the Regina Cold Storage Co. have been sold for $27,000.

Lethbridge, Alta.—Delany's, Ltd., have installed a $5,000 ammonia cold storage plant in their market on Fifth Street.

Montreal, Que.—R. E. Bostrom, McGill Building, Montreal, is the architect for the proposed artificial ice plant for the Montreal Arena Co.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News.

Engineering

Pembroke, Ont—James Sarsfield is in the market for 800-gallon fire engine.

Shawinigan Falls, Que.—The Belgo-Canadian Pulp and Paper Co. will install a new power plant.

Kincardine, Ont.—The Water and Electric Light Commission has purchased a boiler from Hunter Bros. of this town.

Rigaud, Que.—The Rigaud Granite Co. are in the market for a stone crushing plant, cars, electric motors and other equipment.

Weyburn, Sask.—Keely Bros., of Omaha, Neb., have established a temporary plant for making boilers and will later build a modern shop.

Berlin, Ont.—A Toronto syndicate has purchased the plant of the Berlin Central Heating Co. It is proposed to make considerable extensions to the plant.

Montreal, Que.—Damage estimated at $5,000 was done on July 29 when the main building of the Bordeaux Foundry Co., at 6332 Bordage Street, was gutted by fire. The origin of the blaze is unknown.

Prince Rupert, B.C.—Mr. T. W. Sheffield, formerly Industrial Commissioner of Regina, is reorganizing the Rupert Marine Iron Works, an industry which promises to be of great importance to this city.

Stony Mountain, Man.—Good progress is being made on the power house and station for the street railway, which is being built in Oak Park. The steel is already laid to this point, ready to bring in the machinery.

Medicine Hat, Alta.—The Saskatchewan Bridge and Iron Co. is now employing a large force of men in the completion of their new plant, the steel work being already up. By fall, according to the plans of the directors, the factory should be in full operation. About one hundred hands will be employed in the new plant, and a capital investment of something like $100,000 is involved.

Penticton, B.C.—The Okanagan Valley Electric and Power Co. has completed the purchase of the Oroville electric light plant from the Similkameen Power Co. It is stated from a reliable source that the company intends to develop the power at the Similkameen Falls to the fullest extent, with the purpose in view of operating an electric line, the northern terminus of which will be Penticton.

Edmonton, Alta.—Six million dollars is the estimated cost of a hydro-electric plant which may be installed in the Saskatchewan River, fifty miles west of here, by Sir John Jackson & Co., of Glasgow, Scotland. The plan contemplates the development of 40,000 horsepower. Representatives of Sanderson & Porter, of New York, submitted an offer to the municipality two weeks ago to install a plant, costing $3,500,000 to supply electrical power to the city on a sliding scale, ranging from one cent to a half cent per k.w.h., according to the quantity used. Under this plan the minimum guarantee is 5,000,000 k.w.h. a year. The council will deal with these propositions within the next two or three weeks.

Electrical

Bolton, Ont.—Result of voting here last Monday on Hydro-Electric by-law was 120 for and 4 against.

Strathroy, Ont.—Hydro power, it is expected, will be turned on here early in September. Wiring operations are now being rushed along.

Weston, Ont.—Now that the matter of electric lighting on Scarlett road has been completely dealt with, the Weston Hydro Commission will take up the extension of a line into York Township.

Toronto, Ont.—Plans, submitted by the Toronto Hydro-Electric Commission, for a one-storey brick and stone addition to the Macpherson Avenue sub-station, have been approved by the city architect's department. The addition will cost $15,000.

Walkerville, Ont.—The town is to have light and power competition, the same as Windsor, the Hydro-Electric Power Commission offering to pay $75,000 for the plant and stores equipment of the Walkerville Light & Power Co., while the company held out for $9,500 more.

Brampton, Ont.—In response to a petition of Robert Noble Co., Ltd., millers of Norval and twenty other ratepayers of the village, the council of the township of Esquising has passed a resolution to the effect that the council contract with the Hydro-Electric Power Commission to obtain a supply of power for Norval.

Brantford, Ont.—Work on the hydro-electric branch line between Brant sub-station and Port Dover is to be commenced immediately, and in a short time power will be available for Burford, Scotland, and elsewhere. Engineers have been over the ground and have laid out a route. The construction of the line will be gone ahead with as rapidly as possible.

Waterloo, Ont.—The demand for hydro power in Waterloo and vicinity is constantly increasing. The Hydro-Electric Commission is taking steps to supply the farming community west of the town and have a number of men engaged in the erection of a line from Waterloo which will supply the farmers with current for lighting and power purposes. It is expected that it will be completed within two weeks.

Windsor, Ont.—In connection with the extension of the main transmission line—St. Thomas to Windsor—it is reported that the Provincial Hydro-electric Commission were able to deliver power in Windsor on August 1. It is understood, however, that Windsor is not quite ready with its distributing plant, and that a week or two may elapse before such is available. The new line between Dundas and Niagara is expected to be completed by the beginning of September. About eighteen miles of concrete footings have already been carried through, and thirty men are working at the rate of about a mile of footings in a day.

General Industrial

Wingham, Ont.—The Bell factory, of the Canada Furniture Co., is at present undergoing repairs.

Hull, Que.—The machinery and plant of the Canada Cement Co. has been badly damaged by fire. A loss is estimated at $25,000.

Galt, Ont.—It is announced that purified gas will be delivered to Galt by September 1. Construction of the purification plant at Glenwood is proceeding in a satisfactory manner.

Sarnia, Ont.—It is understood that Hon. W. J. Hanna, who is in England at present, is endeavoring to secure for this

city the proposed Canadian branch of a large British smelting concern.

Hamilton, Ont.—Mayor Allan announced that it is almost certain that the United Gas & Fuel Co. will build a $1,500,000 coke and gas plant here, as was first announced several months ago.

Iroquois Junction, Ont.—The first pulp ever manufactured in Timiskaming was made on July 29 in the big machines at the plant of the Abitibi Pulp and Paper Co. Regular production and daily shipments of pulp started last Monday.

Cobourg, Ont.—Geo. Thompson, of the Thompson-Macdonald Co., is promoting a new industry here for the manufacture of drain tile. The project is to form a syndicate to purchase a drain tile machine and make tiles here.

Windsor, Ont.—The Ideal Concrete Machinery Co. has closed the contract for its new factory branch on McDougall Avenue. The building will be started without further delay and the company expects to be in operation in September. The manager of the company will be C. F. Pulfer, formerly of Walkerville.

Port Arthur, Ont.—A brick plant is to be established on the property of the Canadian Resources Development Co. At first the plant will turn out 5,000 bricks daily, which will eventually be increased. It will be in operation this fall, the material for the erection of the plant having been already shipped from England.

Brantford, Ont.—Operations are now going on for the reconstruction of the Canada Glue Works at Echo Place, after the fire that destroyed the plant there last April. Work has been going on now for the past six weeks. Construction has now begun on the walls of the new building which will be larger and better equipped than the old plant. Up-to-date machinery will be installed.

Beamsville, Ont.—President Jas. Ross of the Dunnville, Wellandport and Beamsville Railway has announced that the Hydro Commission has agreed to take over the D., W. & B. Railway and complete it to Beamsville. The plan, according to Mr. Ross, is to make this line a feeder for the main line ,which the Commission is now surveying for between St. Catharines and Hamilton.

Bridgeburg, Ont.—A branch of the Hard Mfg. Company, of Buffalo, may be located here, providing negotiations at present under way are consummated. The company ask that fifty thousand dollars stock be subscribed locally. This, it is thought, can be arranged for without any serious difficulty. An option has been secured on five and one-half acres of land adjacent to Crook Street.

Estevan, Sask.—F. W. Newcombe, manager of Estevan Brick & Coal Co., is at present in Mason City, Iowa, making arrangements for the installation of new dies at the brick plant here for the making of hollow brick and other kinds of hollow ware. The change will also necessitate some new kilns being built, as a special process is required in the drying different to the method now being used at the plant.

Granby, Que.—Work on the installation of the new power plant at the Empire Tobacco Factory is expected to commence very shortly. There is much work to be done, including the excavation of a tunnel and the placing of new machinery, so that it will be several months before the new building is occupied and the extra plant in active operation. About four hundred hands are at present employed, which will be increased as business improves and the new additions to this establishment are completed.

Dundas, Ont.—In the course of the next few weeks Dundas will have another manufacturing plant added to its list. The Mercury Mills, Ltd., of Hamilton, has taken a two years' lease of one of the plants in the old cotton mill, now used by the Chapman Engine Works, and intends establishing a branch factory here. Workmen are now engaged in making extensive alterations and repairs, and as soon as these are completed the machinery for carding and spinning of the finer classes of woollen yarns will be installed.

Toronto, Ont.—The incorporation notice of the National Explosives, Ltd., a company capitalized at $2,000,000, with head office at Toronto, appeared recently in the Canada Gazette. Mr. Gerard Ruel, solicitor of the C.N.R., states the company is being formed in connection with a reorganization of the Olympic Powder Co., which has a dynamite and explosive manufacturing plant at Deseronto. The incorporation of the new company is merely a financial reorganization, and does not mean that the plant will undergo any changes.

Municipal

Rosetown, Sask.—The ratepayers have passed a by-law for the purchase of fire-fighting equipment.

Ottawa, Ont.—The Board of Control have decided to purchase road repairing equipment immediately.

St. Thomas, Ont.—The City Council has authorized the expenditure of $20,000 on repairs and improvements to the gas plant.

Guelph, Ont.—The new artesian well near the pumping station is supplying about 50,000 gallons of water per day to the reservoir for city use.

St. Thomas, Ont.—The City Council has authorized the expenditure of $20,000 on repairs and improvements to the present city gas works plant.

Montreal, Que.—The city will shortly call tenders for 200 lamp standards with cable connections. The new standards will be of the single lamp type.

Stratford, Ont.—The Fire, Light and Cemetery Committee of the City Council signed the contracts for its new fire fighting apparatus last Friday.

Outremont, Que.—The purchase of road-making equipment, including concrete mixer, steam drill and a tar kettle, has been sanctioned by the council.

Regina, Sask.—The City Council has awarded to the Regina Foundry Co., Ltd., Regina, the contract for fabricating the steel work for the new 5,000,000 gallon reservoir.

Dutton, Ont—By a unanimous vote the ratepayers last Friday endorsed a by-law which provides for a supply of gas for the municipality from the Southern Ontario Gas Co.

New Toronto, Ont.—Plans for the new pumping station in connection with the waterworks system have been approved by the Board of Health, and as a result tenders will be called shortly.

Vernon, B.C.—The city will spend $100,000 on improving the sewage system. A new disposal plant will be erected. Cummins & Agnew are the engineers.

Courtright, Ont.—Great progress has been made under direction of O. M. Post, of the Union Gas Co., in laying the pipe lines into this town, and this week will likely see this part of the work completed.

Montreal, Que.—Tenders for the erection of a fire and police station for the town of Maisonneuve, at a cost of $70,000, will be called shortly by the architect, Marius Dufresne, Ontario Street, Maisonneuve.

Winnipeg, Man.—Two sets of preliminary plans for better traffic facilities at the St. James subway have been placed before the works and property committee by the Winnipeg Electric Railway Co.

Sarnia, Ont.—City Engineer McLean states that if nothing goes wrong, the new waterworks, under construction at the lake shore, will be pumping water by the

beginning of August. The last shipment of pipe has been received.

Victoria, B.C.—To provide for the installation of the water supply, the Saanich Council on July 14 authorized a call for tenders for the material required for the system, and decided to take up the necessary by-law for the undertaking at a special meeting of the council at an early date.

Berlin, Ont.—The Berlin Water Commission have taken steps to have a filtration plant installed at the lake on Shoemaker Avenue. Work will begin at once, and is expected to be completed by September 1st. The water which was previously taken from the Glasgow Street well, is too hard.

Chatham, Ont.—The Council has decided to purchase new ladders for the present hook and ladder truck, and not purchase a motor truck at the present time. The ladders will be of such a character that they can be made part of the equipment of a motor truck when that machine is purchased.

Regina, Sask.—About two hundred letters have been received by Publicity Commissioner Ruse from firms in the East and the States to whom his department has mailed copies of a booklet illustrating the points of interest in Regina, and setting forth the city's claims as a desirable place for industries to locate.

Chatham, Ont.—A resolution has been adopted by the City Council authorizing the committee to open negotiations with the Hydro Power Commission for current. The report also stated that all negotiations with the Chatham Gas Co. are at an end, as the company had refused the recommendation of the Commission.

Carleton Place, Ont.—The waterworks contractors have commenced on their operations of crossing the river. After this contract there will be only a short distance to finish, and as work has already been started on the power house and septic tank, it will not be long before water supply service will be completed.

Stratford, Ont.—The council have finally decided to purchase the following fire-fighting apparatus:—One type 12 combination chemical engine and hose car, motor-driven; one second size city service hook and ladder truck, for $9,055, and the old fire engine; one 800-gallon capacity Waterous fire engine,

Peterborough, Ont.—A by-law will be voted on to give the city power to expropriate the property and plant of the Peterborough Light and Power Co. The by-law will also give power to the city treasurer to make a cheque payable to the Power Committee for the sum of $100,000, the purchase price of the property of the Peterborough Light and Power Co.

Stratford, Ont.—After some weeks of hard work on the part of the Hydro-Electric Commission's engineer and a large staff of workmen and the Stratford Light and Heat Commission, the new street lighting system for the main thoroughfares was completed last Friday and tested for the first time. On Saturday night it was turned on for the opening of the regular service.

Sherbrooke, Que.—By an overwhelming vote, 720 to 89, the ratepayers of this city on July 27 defeated the by-law to borrow $200,000 for permanent work on the streets of the city. Those who opposed the measure took the stand that the City Council had not given a proper statement of the city's financial standing, and until such time as this statement was available, they would vote no more money.

Swift Current, Sask.—The Local Government Board at Regina has authorized an issue of debentures by the town of Swift Current to total $196,000 for the financing of necessary local improvements. Of this amount, one issue will be for sewer construction amounting to approximately $112,000; one for an electric lighting plant at $60,000; and a third to provide for concrete sidewalks totaling $15,000.

Regina, Sask.—The city is considering sites suitable for stock yards and abattoir. Two properties have been inspected, but before a selection is made it is likely that other locations will be considered. The city has had the question of locating stockyards and an abattoir at Regina under consideration for some time past, and it is expected that in the immediate future definite steps will be taken with this end in view.

Calgary, Alta.—Four by-laws will be submitted to the ratepayers on next by-law voting day, which has been set for August 14. These are the by-laws authorizing the expenditure for the Fourth Street west subway, the exact amount of which has not yet been determined; the Ninth Street bridge, $165,000; the Hillhurst athletic park purchase, $60,000; and $80,000 for waterworks extensions in the northern section and other parts of the city.

Moncton, N.B.—Work is almost completed on the big McNutt Brook reservoir, which has been constructed for the city, four and a half miles from the city limits, at Cherryfield. When the reservoir is finished a big lake will be formed over a mile in length and covering an area of some ninety acres. The work is so far advanced that it is expected the reservoir will be connected with the city and in actual use during the coming fall.

Hamilton, Ont.—Engineer Macallum's plan for the alteration and enlargement of the east end disposal works is to have two-storey septic tanks, and to treat the sewage with merely the screens and the tanks. The estimated cost would be $141,000, made up of $82,000 for the alterations to the present plant to allow for the increase of sewage, and the balance for the addition of new tanks which will be required in the near future to accommodate the east end sewage.

Charleswood, Man.—The ratepayers turned down two by-laws on July 18, aggregating $65,000. One by-law was for a new gravel road to be built under the Manitoba Good Roads Act and called for an expenditure of $60,000. The other was for a new municipal hall, to be erected one mile beyond the terminus of the Tuxedo Park car lines. In each case the majorities against were large. The defeat of the road by-law was probably due to the desire of the electorate to wait and secure a paved highway instead of a gravel road.

Calgary, Alta.—Waterworks Engineer Fawkes will recommend to the council that Walsh & Charles, with Trident Disc Meter, receive the contract for 40 of the 50 three-quarter inch meters required by the city at the price of $16.38 each, and that the remaining ten be supplied by the Western Supply Equipment Co., with Siemens meters, at a price of $10.70 each. He will also recommend that the 100 one-inch meters be awarded to the National Meter Co., with No. 9 Nash meter, at the price of $21.80 each, and that the contract for the 20 two-inch meters be divided between the National Meter Co. and Walsh & Charles as follows:—Ten No. 9 Nash, National Meter Co., at $65 each; ten Trident, style 3, Walsh & Charles, at $65 each.

Railways - Bridges

New Westminster, B.C.—The plans for a new station submitted by the Great Northern Railway to the Council, have been approved.

Cornwall, Ont.—The contract for the erection of the Cornwall station of the Glengarry and Stormont Railway has been let to Atchison & Co. and Henry Williams, of Cornwall. The work will be commenced at once.

St. Thomas, Ont.—A re-opening of negotiations with the London and Lake Erie Transportation Co. for an extension

of the line to Aylmer and Port Burwell is anticipated by the Aylmer and other interested municipalities.

Ottawa, Ont.—The councils of the Township of Williamsburg and Winchester held meetings recently and gave first and second readings to by-laws to guarantee bonds for about one-sixth of the cost of construction of the Morrisburg and Ottawa Electric Railway.

London, Ont.—The London & Port Stanley Railway, the city's road, the electrification of which the ratepayers authorized last January, is being reconstructed at the rate of a mile a day, and will be in operation very shortly. The Pere Marquette has the rehabilitation contract.

Montreal, Que.—The plan for the temporary station which the C.N.R. will erect at the corner of St. Monique and Laganchetiere streets have been completed by Messrs. Warren & Wetmore, architects. They show a building two storeys high above the street level and one storey below. The measurements are 150 feet frontage and 100 feet depth along St. Monique Street. The station will be constructed in steel and concrete. The facade will be finished in stucco and embellished with several marble columns. The baggage will be handled in a separate portion of the building in the rear approached by special driveways. The station, which will be completed by May 1, 1915, will cost $250,000.

Ottawa, Ont.—Work towards the completion of the National Transcontinental Railway is being rushed forward. Late last fall the steel on the whole eastern division was linked up, and since then the engineers have been at work getting the roadbed in shape for carrying traffic. Eleven thousand men are now engaged at this work, and the expectation is that the whole line will be ready for operation by October. The big car ferry Leonard, built in England, will be ready to carry trains between Quebec and Levis, thus providing through communication over the whole line of the Transcontinental. Early rumors that the Grand Trunk Pacific would be unwilling to take over the eastern division are not being borne out as time goes on. The line is being completed in accordance with the provisions of the contract, and the Grand Trunk Pacific is giving no sign of a disposition to evade carrying out its share of the arrangements.

Pacific Great Eastern.—The contractors for the construction of the Pacific Great Eastern Railway are rushing work with all haste. Several thousand men are now employed along the route between the Cheakamus Canyon and Fort George. The entire line is now in course of construction, sub-contracts having been awarded by Mr. P. Welch. Track laying is in progress beyond Cheakamus, where a number of bridges have recently been completed. Steel has already been extended twenty-eight miles north of Squamish, the ocean terminus of the P.G.E., towards Pemberton Meadows, and a large force of men is engaged in this branch of construction work. Practically all the grade has been finished between Squamish and Lillooet, a distance of 120 miles. On the section between Clinton and Lac La Hache ten per cent. of the grading has been accomplished. The line is expected to be ready for the rails between Clinton and Lillooet later in the year.

Tenders

New Toronto, Ont.—Tenders are being received until August 3 for the construction of pump well, pumps, filters and pump house.

Regina, Sask.—Tenders are being called for the installation of an electric lighting system in the new wing of the General Hospital.

Orillia, Ont—The date of receiving tenders for sections (E), (F) and (G) covering equipment for the waterworks extensions has been extended to Aug. 24.

Moose Jaw, Sask.—Tenders will be received up till Wednesday, August 26, 1914, for high pressure steam pipe and appliances for a 3,500 horse-power plant. Plans and specifications may be obtained upon application to J. D. Peters, electrical superintendent, Moose Jaw.

Winnipeg, Man.—Tenders will be received up to Monday, August 10, 1914, for the "mechanical coal and ash handling plant," central power house, Winnipeg. Plans, specifications, conditions of contract, and all particulars may be seen at the office of the Provincial Architect, 261 Fort street, Winnipeg.

Winnipeg, Man.—Tenders will be received up to Monday, August 10, 1914, for the "heating and plumbing, pumps, heaters, etc.," Central Power House, Winnipeg. Plans, specifications, conditions of contract, and all particulars may be seen at the office of the Provincial Architect, 261 Fort street, Winnipeg.

Montreal, Que.—Tenders will be received up till August 11 for supplying and erecting at the low level pumping station a 24,000,000 imperial gallon steam turbine driven high lift centrifugal pump. Plans and specifications may be obtained from the Superintendent of Waterworks, City Hall, Montreal, Que.

Ottawa, Ont.—Tenders will be received until August 6 for the construction of a Drill Hall at Powassan, Ont. Specifications may be seen and full particulars obtained at the office of the Officer Commanding the 2nd Division, 215 Simcoe Street, Toronto; the Town Clerk, Powassan, Ont., and the Director General of Engineer Services, Headquarters, Ottawa.

London, Ont.—Tenders will be received up to August 7 for steam piping and fitting to new boilers at the incinerator in conjunction with the heating of Victoria Hospital. Copies of specifications may be seen in the city engineer's office, and all further particulars secured on application to H. P. Elliott, consulting engineer, 484 Ridout Street, London, also of Toronto.

London, Ont.—Tenders will be received up to Friday, August 7, for the furnishing of steam boilers at the incinerator in conjunction with the heating of Victoria Hospital. Separate tenders will be received for setting the boilers. Copies of specifications may be seen in the city engineer's office, and all further particulars secured, on application to H. P. Elliott, consulting engineer, 484 Ridout Street, London, also of Toronto.

London, Ont.—Tenders will be received at the office of the City Clerk up to Friday, August 7, for the furnishing of steam boilers at the incinerator in connection with the heating of Victoria Hospital. Separate tenders will be received for setting the boilers. Copies of specifications may be seen in the City Engineer's office, and all further particulars secured, on application to H. P. Elliott, consulting engineer, 484 Ridout Street, London, also of Toronto.

Winnipeg, Man.—Tenders will be received up to Saturday, September 19, 1914, for the construction of eighty-five miles of concrete aqueduct in five sections of approximately equal length. Plans, specifications and form of tender can be secured by application accompanied by certified cheque for one hundred dollars, which deposit will be returned upon submission of tender or return of documents. S. H. Reynolds, chairman of commissioners, 901 Boyd Building, Winnipeg.

Canora, Sask.—Tenders will be received until August 18 for the following works:—(A)—Laying cast iron water mains. (B)—Construction of pump house. (C)—1, Construction of steel water tower; 2, construction of concrete foundation; 3, housing of water tower. (D)—Furnishing cast iron pipes and specials. (E)—Furnishing fire hydrants and valves. (G)—Furnishing and erecting

"WILLIAMS" MACHINERY LIST

New Machine Tools in Stock

New Engine Lathes.

12 x 6′ R. K. Le Blond.
14 x 6′ American Tool Works.
14 x 6′ Fay & Scott.
14 x 6′ Cisco.
16 x 8′ Le Blond.
16 x 6′ Canada Machinery Corporation.
16 x 8′ Rockford.
17 x 8′ Le Blond (Heavy Duty).
18 x 10′ Hendey (Taper Att.).
18 x 8′ Stevens Co.
18 x 8′ Canada Machinery Corporation.
24 x 16′ New Haven.
28 x 14′ New Haven.
26 x 48 x 16′ McCabe "2 in 1."

New Milling Machines.

No. 2 Schuchardt & Schutte Plain.
No. 2 Hendey Universal.
No. 2 Le Blond Universal.
No. 3 Hendey Universal.
No. 3 Le Blond Plain.
No. 2A Kearney & Trecker Plain.
No. 3B Kearney & Trecker Plain.

New Shapers.

14″ Smith & Mills.
16″ Schuchardt & Schutte.
16″ Walcott.
16″ Canada Machinery Corporation.
16″ Smith & Mills.

New Grinders.

Cincinnati Universal Tool & Cutter Grinder.
Le Blond Tool and Cutter Grinder.
Walker Outfit "D."
Stevens Universal Tool & Cutter Grinder.
No. 3 Brown & Sharpe Universal.
Gardner No. 4 Disc Grinder.
Diamond 18″ Disc Grinder.
Yankee Drill Grinder.
Assorted stock of Bench & Floor Grinders.

New Drilling Machines.

Kokomo Roller Bearing Sensitive 16″.
Barnes' 10″, 15″, 20″, 22″, 22½″, 25″, 26″, 28″ Drills.
Allen Ball Bearing Sensitive 16″.
Snyder 23″ Tapping Att.
3′ American Radial (Speed Box).
2′ Fosdick Radial.
42″ Rego Radial.

Turret Lathes and Screw Machines.

14″ Warner & Swasey (Auto. Chuck).
16″ Warner & Swasey (Auto. Chuck).
No. 2 Warner & Swasey Screw Machine.
No. 2A Warner & Swasey Universal Hollow Hexagon Turret Lathe.
2 x 24″ Stevens (Jones & Lamson) Turret Lathe, both equipments.

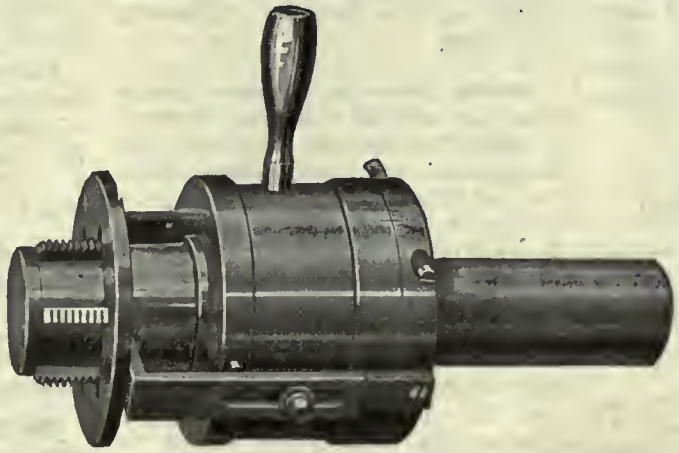
Presses and Punches.

No. 180, 190, 200 Brown Boggs inclinable.
No. 18, 19 Banfield "Bliss Pattern."
No. 2, 3, 4 Brown Boggs "Styles Pattern."
1 x 1 x 24″ Scott D.E. Punch and Shear.
¾ x ¾ x 18″ Scott D.E. Punch and Shear.

MACHINE TOOL DEPT.

The A. R. Williams Machinery Co., Ltd., 64-66 Front St. W., Toronto

A Thread To Tap?



No Time To Waste?

A Geometric Adjustable Collapsing Tap is What You Want.

Whether a Straight Thread, or a Standard Pipe Thread,

The Geometric Will Tap It Out.

Set the trip for the desired length, and when this is reached the chasers will automatically recede. Draw out the Tap. Move handle to again adjust the chasers, and continue your thread tapping

Without Waste of Time, Material or Effort.

Geometric Adjustable Collapsing Taps are for use on Turret Head Machines or on Live Spindles.

ALWAYS TAP TO SIZE. **CHASERS REGROUND OR RENEWED AT SLIGHT COST.**

Send for our Catalogue.

THE GEOMETRIC TOOL COMPANY **NEW HAVEN, CONN.**

pumping machinery. Plans and specifications may be seen at the offices of Chipman & Power, engineers, Toronto and Winnipeg, or at the Town Hall, Canora.

Montreal, Que.—Proposals were received at the office of the Board of Commissioners, City Hall, Montreal, up till Tuesday, August 4, 1914, for the furnishing and erecting at the Low Level Pumping Station of the Montreal Water Works, two water tube boilers, as follows:—(1) one horizontal of 500 h.p.; (2) one vertical of 350 h.p., with all their fittings and appurtenances complete; the whole in accordance with the specifications and plans to be seen and examined at the office of the Engineer Superintendent of Water Works, City Hall, Montreal.

Ottawa, Ont.—Tenders will be received until Monday, August 31, 1914, for the construction of a wharf at Kensington, Algoma District, Ontario. Plans and form of contract can be seen and specification and forms of tender obtained at the Department of Public Works and at the offices of the District Engineers at Sault Ste. Marie, Ont.; Confederation Life Building, Toronto, Ont., and on application to the Postmaster at Desbarats, Ont. Blue prints can be obtained at the Department of Public Works by depositing an accepted bank cheque for the sum of $10, made payable to the order of the Honorable the Minister of Public Works, which will be returned if the intending bidder submit a regular bid. R. C. Desrochers, secretary.

Contracts Awarded

Swift Current, Sask.—The contract has been awarded the A. H. Reid Incinerator Co., Toronto, for a hot blast tube garbage and refuse incinerator of 15 tons daily capacity.

Steelton, Ont.—The contract was awarded recently to Rock & Power Machinery, Ltd., Toronto, for two Hill-Trip centrifugal pumps, each of 600 gallons per minute capacity, and for motors to drive the same.

Toronto, Ont.—The Board of Control has awarded a contract to the McLaughlin Motor Car Co. for the supply of a 1,500 lb. truck at $1,725, and to the Wilson Motor Sales Co. for a 4,000 lb. truck at $2,850.

Welland, Ont.—The contract has been awarded by the Dominion Government to A. T. Bradley, St. Catharines, and David Walker, Thorold, for the stone protection required on the Summit Level of the Welland Canal, between Thorold and Port Colborne, Ont.

Calgary, Alta.—The contract for the first building of the Calgary University has been approved by the building committee of the university. The work goes to Archibald & Co., Winnipeg. The price to be paid for the building is in the neighborhood of $100,000. P. Harcourt O'Reilly, chairman, Dr. MacRea and Dr. McDougall are members of the building committee.

Toronto, Ont.—Contracts for work in connection with the new Technical School totaling $36,778 were last Thursday awarded by a sub-committee of the Advisory Industrial Committee of the Board of Education, subject to ratification by the board. The successful tenders are as follows:—Refrigeration, Keith's, Ltd., $6,000; filtration, Fred Armstrong Co., $3,800; electricity and gas, A. R. Rice, $8,700; plumbing, Fred Armstrong Co., $20,678.

Regina Sask.—The City Council has approved of the following contracts representing an expenditure of $51,882 for street lighting and generating equipment for the new power house. For a switchboard consisting of 26 panels of blue Vermont marble, to the Canadian Westinghouse Co. at $32,000; for 100 arc lights complete, to the Canadian General Electric Co. at $6,050; and for minor supplies to the Northern Electric Co. at $268, the Maloney Electric Co. at $594, the Siemens Company of Canada at $7,850, and the Burnham Engineering Co., $2,600.

Ottawa, Ont.—The Dominion Government has awarded a contract to the C. S. Boone Dredging and Construction Co. for the dredging at Little Detroit River, Ont., at $12,000. The Soo Dredging Co., Ltd., will fill a dredging contract at Bruce Mines to cost $6,975. George A. Proctor has been given a contract for the construction of a public building at Kingsville, Ont. The price is $25,837. A public building to cost $18,211 is to be built at Burford, Ont., by P. H. Secord and Son. The Dominion Radiator Co. obtained the contract for heating the east block of the Parliament Buildings at $10,200.

Wood-Working

Nanaimo, B.C.—The lumber mill of the New Ladysmith Lumber Co. has been completely destroyed. The loss of $30,000 is fully covered by insurance.

Brockville, Ont.—The Smart Manufacturing Co. will replace their planing mill, which was destroyed by fire a month ago, with an up-to-date three-storey concrete structure.

Marmora, Ont.—Word has been received that the plant at Deer River, belonging to the Trenton Cooperage Mills, Ltd., was totally destroyed by fire, entailing a loss of $10,000 or $12,000.

Goderich, Ont.—The Goderich Lumber Co. has asked for a loan of $25,000 to help them erect a furniture factory over their sawmill. They intend rebuilding their mill and would put the factory up at the same time.

Regina, Sask.—The Watt-Gibson Co. of Toronto will establish a lumber yard and planing mill in North Regina without delay. The site for this new industry has already been secured and no time will be lost in establishing the business here.

Berlin, Ont.—The Berlin Office & Fixture Co., Ltd., has been formed in this city, capitalized at $60,000. The new firm has taken over the Brubacher planing mills and will also erect a large addition for the manufacture of interior hardwood furniture.

Ottawa, Ont.—A fire broke out in Gilmour & Hughson's lumber yards just east of Brewery Creek, Hull, shortly before ten o'clock last Monday night. Three million feet of valuable lumber was destroyed. The estimate of the loss is in the neighborhood of $500,000.

New Incorporations

The Lorne Power Co., Ltd., have been granted permission to increase their capital from $300,000 to $1,000,000.

The Ontario Fertilizers, Ltd., has been incorporated at Toronto with a capital of $100,000 to manufacture fertilizers at Toronto. Incorporators: L. McCaulay, J. C. MacFarlane, and H. J. McLaughlin, of Toronto.

The Neal London Bread Co., Ltd., has been incorporated at Toronto with a capital of $40,000 to manufacture bread, biscuits, etc., at Toronto. Incorporated: H. J. Neal, J. Bridge, and J. Ruddy, of London, Ont.

The Builders Cement Tiles, Ltd., has been incorporated at Toronto with a capital of $40,000 to manufacture brick and tile, etc., at Toronto. Incorporators: J. G. Gauld, C. V. Langs, and L. H. Gray, all of Toronto.

H. R. Goodday Co., Ltd., have been incorporated at Ottawa with a capital of $250,000 to deal in all kinds of lumber and wood at Quebec. Incorporated: A. C. M. Thompson, W. F. Fanning, and H. G. Blair, all of Quebec.

The Arnprior Felt Co., Ltd., have been incorporated at Ottawa with a capital of $50,000 to manufacture felt and woollen goods at Arnprior. Incorporated: J. T. Griffith, M. Sullivan, and J. Cunningham, all of Arnprior, Ont.

Electrical Equipment for Motor Driven Machine Tools-I

By C. Fair *

The importance of motor drive for the machine shop is every day becoming more evident and more thoroughly appreciated, and it is worthy of note that in practically all new industrial plants where power is required, electrically-driven machinery has been installed. Little trouble is now experienced with either motors or control for the ordinary type of machine tool, due largely to a better understanding of the situation between machine builder and user.

ORIGINALLY, lighting was the principal, if not the only, advantage claimed for electricity. Little was known of shop equipments as we now see them. It is doubtful if there were any electrically operated cranes or if there was any electrical transportation in shops. The first few motor drives were scattered and confined practically to line shaft drives and to portable drills with flexible shafts, while the individually driven machine tool was about as much of a curiosity then as an individually steam engine driven machine tool is to-day. When motors were installed to replace the numerous engines scattered about the shops or to break up the long mechanical transmission lines, a great saving in power and improvement in continuity of service were noticed, and it was during this period that many of the claims of saving in power were made that now appear rather extravagant.

It will be seen how enormous were the power losses when one considers that steam was often transmitted to numerous engines for long distances, from one or more power stations, through small pipes which were often uncovered, or else the power was distributed by long shafts transmitting power from one building to another or from one shaft to another, around corners, by quarter turned belts and to various floors, etc. When the long shaft or any part of the long transmission system was broken, it often tied up a large part of the plant until key-ways could be cut and the shafts re-coupled or a section of the shaft replaced, or the belts repaired, as the case might be.

The Manufacturers' Attitude.

To-day the two important questions continually before the manufacturer are how to increase production and how to decrease cost. In the majority of cases labor is the greatest cost of production. Thus, where machine tools are a considerable factor in the production, the importance of obtaining a maximum output from the tool is evident. Tools that are limited in their productiveness because of the lack of power at the tool are a source of expense to the manufacturer, not only on this account, but on account of the excessive labor due to the additional time required. The power cost of production is comparatively small, roughly, varying from one to three per cent., while the labor cost is usually a very large item of the production cost, often amounting to 50 per cent. and upward. If, therefore, by increasing the power on a given tool its output can be increased, the conclusion is obvious.

Motor Drive Importance.

The importance of motor drive for the machine shop is every day becoming more evident. Recent tariff legislation is causing American manufacturers to see, as never before, the necessity of using the most modern methods in order to compete with manufacturers of other countries where labor is cheaper; hence the continuous growth in the installation of electrically driven machinery. In practically all new industrial plants where power is required, electrically driven machinery has been installed. Due to the great improvement in motors, accessories, and methods of application, and owing to the large number and variety of motor-driven tools in service to-day, the relationship of motors and control to machine tools is much better understood by the machine builder and the user than heretofore. Consequently, comparatively little trouble is experienced with either motors or control for the ordinary type of machine tool. Misapplications of both motor and control occur occasionally, due largely to insufficient or unreliable information regarding the characteristics of the machine, but the number of these misapplications is relatively small.

The tendency for both over and under-motoring machines is constantly growing less, owing to the large number of tests which have been made, to the accurate information available, and to the great number of motor-driven machines now in service. There is still, however, a slight tendency on the part of some machine builders to over-motor their machines either with the mistaken idea of the strength of the machine or with the idea that possibly prospective customers will be impressed with the enormous power required by their "heavy type" machines.

Conversely, other manufacturers want to show how little power it takes to operate their "very efficient" machines, and consequently get into overloaded motor troubles. These extremes are gradually disappearing, and a more normal condition is taking its place. In a comparatively short time the greatly over-motored and under-motored machine will be a thing of the past, at least in so far as the general type of machine is concerned.

Motor Drive Ratings.

A number of manufacturers have already recognized three ratings of motor drive on certain of their machines; namely, heavy, medium, and light. Much of the existing trouble in motor applications to special machines, or to machines rigged for special operations, could easily be avoided if only preliminary tests were made with a temporary motor before making the permanent installation. A not uncommon source of trouble with motor-driven tools, and one that could easily be avoided, is that of attempting to increase the productiveness of the tool considerably by speeding up the machine, increasing the cuts, or attaching automatic feeding devices, etc. Although any one of these changes will increase the productiveness of the tool, the motor must not be overlooked for, if the tool were originally under-motored and the capacity of the motor is not increased when the change is made, trouble is very apt to result. Increasing the productiveness of the tool calls for an increase in power, although there are some cases where this is not true.

Motor Drive Advantages.

Although the advantages of the motor drive have been dwelt upon at length numerous times, a brief statement of the advantages derived from electrical installations will perhaps be worth repeating:

1.—Maximum output of the direct connected tool, due to greater power and overload capacity, absence of slipping belts, closer speed regulation which allows a maximum cutting speed for metals of varying degrees of hardness, rapid speed changes, quick starts, stops, reversals, independent operation of auxiliaries and ease of manipulation through convenient control stations. Too much stress cannot be laid on maximum output of tools.

2.—Power distribution not only for

*Power and Mining Engineering Department, General Electric Co.

tools, stationary or portable, but for lights, cranes, elevators, furnaces, welders, transportation, etc. This means that power and light can be had quickly and cheaply in any part of the buildings or yard, permanently or temporarily without regard to structural conditions.

3.—Elasticity in the arrangement of tools. Tools can be arranged to the greatest advantage for sequence of operation in routing work, and also for good lighting as well as for compactness when necessary.

4.—Ease of adding new tools and of moving and rearranging tools. Ease of adding new tools means a great deal in growing plants. Rearrangement becomes necessary after reasonable growth or because improvements in methods of manufacture call for a better routine of work.

5.—Head room for cranes, hoists, etc. For example, note the expensive manner in which work is often handled because belts or shafting interfere with the installation of cranes or hoists.

6.—Facility for running only such tools as are required for overtime work.

7.—To a large extent the elimination of belts and belt troubles.

8.—Unobstructed light and sanitation. Numerous belts obstruct light, whether natural or artificial. Under the modern structural conditions, avoidance of the well understood difficulties of line shaft installation in concrete buildings.

9.—Safety to operators. The individual motor drive offers absolute protection to the operator from accidential starting up of the machine by merely opening a switch. Machines so protected cannot be started unexpectedly by the starting up of line shaft, the creeping of belts from loose to tight pulley, the sticking of clutches, etc., or by the accidential tripping of clutches by the operator. This additional safety is of particular advantage on machines requiring certain setting up operations, as on punch presses, etc., also by the fact that machines can be quickly stopped from any one of a number of motor control stations.

10.—Competition to-day necessarily means the monotonous duplicate system of manufacturing wherein the individual makes only one part of the finished product. It is now recognized as not only desirable but as economical that some form of interest be restored to help break this monotonous routine of duplicate manufacturing. This can and is being accomplished in a manner by making the surrounding attractive. Electric drive not only increases production, but reduces to a minimum many of the unattractive features of the shop, such as overhead revolving pulleys, masses of moving belts, noisy transmission, stirring up of oil and dust, and bad lighting conditions. Electric drive also reduces many heavy manual operations to a minimum by the use of auxiliaries. It pays to capitalize cheerful surroundings.

Increased Cutting Speed Feature.

The general use of high speed steel has made it not only possible, but necessary for economical production, that the cutting speed be increased in order to meet competition. Increasing the cutting speed naturally means more power; and while much has been said from time to time regarding the increased production and saving in power due to applying the power direct to the tool, yet the writer has very serious doubts if anything like the real importance of this direct application of power is realized in many cases, even by those who are advocating it. For instance, the saving of power is looked upon generally as a matter of how much of the transmission friction load can be saved, and, though this saving may amount to 50 per cent., it is in many cases only a part of the real saving, as has been proved by numerous tests made by the writer.

The slipping, due to a belt not being able to pull its cut, means waste power and loss of production. If the cut be heavy enough, the maximum slip will be reached when the machine is stalled, the power input remaining approximately the same. The load is now entirely one of friction due to slip in the belt. A familiar illustration of this fact is that of an operator decreasing the depth of his cut on account of the slow down, because the belt will not carry the load. The solution of this would seem to be to increase the size of the belts. This will suffice in some cases, but there are numerous instances where either there is not room to increase the width of the belt or where step cones are used the number of steps will have to be decreased; such means as multiple countershafts or additional gearing being included to complete the speed range. Furthermore, it is difficult to shift large belts, and this method generally results in much loss of productive time.

As previously mentioned, up until a few years ago in the majority of shops where motors were used they were usually belted to the line shaft or countershaft of the tool. Adjustable speed motors were not so commonly used then as now, nor were they made in the great variety of sizes and speeds now obtainable. To-day, especially in the case of new tools with their requirements of high power and close speed regulation, it becomes not only more convenient, but in many cases almost a necessity, to apply the motor directly to the tool.

In driving tools with individual motors it will be noted that the motor not only supplies the power and speeds best adapted to the tool, but that in the case of variable speed tools the speed range of the adjustable speed motor alone in many cases will cover the entire speed range of the tool. The motor and its controlling apparatus should whenever possible be connected directly to the tool, thus making a compact unit. This has also the additional advantage of allowing the entire machine to be moved by simply disconnecting the leads and connecting them in the new position. In the case of portable tools this, of course, is an absolute necessity.

Kind and Power of Motor.

Many tests have been, and are being made, to determine the kind, and the horse power of the motor that should be used for different types and sizes of tools; but to the present time the motor is generally considered only as a means of driving the tool and not as one of the main elements of the tool construction. Recent motor improvements will produce many new designs in tools with corresponding higher efficiencies.

While there are numerous motor applications to machine tools which are a decided credit to the machine designers and for which due credit should be given, there are still many motor applications where it is only too plainly to be seen that the motor is an after-thonght and thus much of the advantage of the application is lost. In order to derive the greatest advantage from motor drive, the motor should as far as possible be direct-connected to the machine. There are to-day many cases where motors are driving machines through nnnecessary auxiliary apparatus. This additional apparatus not only takes up valuable floor space and wastes power, but fails to give the maximum output available when the motor could be connected directly to better advantage and in some cases at actually less cost.

From the foregoing it will be seen that the advantages derived from an up-to-date direct method of applying the motor not only increases the productiveness of the tool, but also decreases the actual power required, by the extent of the friction load loss, and also decreases the first cost of the motor on account of the less horse power required. The writer knows of cases where improved drives have cut the power required to half and even less. A cheap first cost is sometimes an expensive investment.

The advantages of individual motor drive for large tools and for certain of the smaller tools have been conceded for years, but there are many tools where either the cost of the motor or the cost of applying the motor to the tool on account of the construction of the machine is prohibitive. This cost could be modified in making the motor a part of the tool rather than a mere addition to it.

The Coming Foundrymen's Convention and Exhibition

Despite the general business depression in existence for a considerable period previous to the outbreak of an all-European war, with all its horrors, and the certain further dislocation of industrial enterprise, there is ample evidence that in attendance, quality, quantity and influence of subjects to be discussed and manufactures exhibited, this combination function will surpass all of its predecessors.

THE advance programme for the Annual Convention of the American Foundrymen's Association at Chicago, September 7-11, has now been prepared, and will be generally as follows:—

Monday, September 7.—Registration at the LaSalle Hotel.

Tuesday, September 8, 10 a.m.—Joint meeting with the American Institute of Metals and Associated Foundry Foremen at the LaSalle Hotel. Formal addresses to be followed by a number of papers on "Safety Work in Foundry Operations."

Tuesday, 2 p.m.—Individual session of the American Foundrymen's Association at the LaSalle Hotel. Papers will be presented on "Foundry Construction and Equipment."

Wednesday, September 9, 10 a.m.—Joint meeting with the American Institute of Metals at the Saddle and Sirloin Club, adjacent to the International Amphitheatre, where the Foundry and Machine Exhibition Co. will conduct its big exhibition of foundry equipment and supplies. This session has been termed a "Cost Congress." Papers will be read and addresses delivered on the necessity of obtaining accurate costs in foundry operations. How to make bids for work will be discussed, and a report on this all-important subject will be submitted. The cost committee of the American Foundrymen's Association will present its annual report, suggesting a revision of the Standard Foundry Cost System and a number of papers will be read on "Efficiency in Foundry Operations."

Wednesday, Noon.—Ladies' luncheon at the Stockyards Inn.

Wednesday, 2 p.m.—Entire session devoted exclusively to the discussion of "Malleable Foundry Practice."

Wednesday Afternoon. — Stockyards inspection.

Wednesday Evening.—Visit to the White City.

Thursday, September 10, 10 a.m.—This session will be devoted to "Steel Foundry Practice," the programme being prepared by R. A. Bull, senior vice-president of the American Foundrymen's Association.

Thursday, 2 p.m.—This session will be devoted exclusively to the presentation of papers and the discussion of "Grey Iron Foundry Practice."

Thursday Evening.—Banquet at the LaSalle Hotel, for members only. Speeches will be limited to one or two addresses by speakers of national fame. Banquet for ladies at the LaSalle Hotel.

Convention Papers.

We are advised that both the American Foundrymen's Association and the American Institute of Metals have prepared technical programmes of unusual length, and which will contain many features of interest to all foundrymen. Practically forty papers and reports will be presented and discussed by the members of the American Foundrymen's Association at their various sessions. A partial list of papers and reports follows:—

Papers on Safety Work.

"Safety in Foundry Operations," address by M. W. Alexander, General Electric Co., West Lynn, Mass.

"Safety First," by W. F. Riedenbach, Genesee Metal Co., Rochester, N.Y.

"Progress in the Safety First Movement," by Arthur T. Morey, Commonwealth Steel Co., St. Louis.

"Safety in Connection with Grinding Wheel Operations," by R. G. Williams, Norton Co., Worcester, Mass.

"Safety and Sanitation," by A. W. Gregg, Bucyrus Co., Milwaukee.

"Safety First—Driving Back the Saloon," by Thomas D. West, Cleveland.

Foundry Equipment and Appliances.

"Electric Motors and Controllers for Foundry Operations," by S. H. Libby, New York.

"The Second Storey Foundry," by G. K. Hooper, Hooper-Falkenau Engineering Co., Detroit.

"Economics of Motor Drive," by H. F. Stratton, Electric Controller & Mfg. Co., Cleveland.

"Abrasives in the Foundry," by Mr. Dietz., Norton Co., Worcester, Mass.

"Refractory Material," by — Kelly, Harbison-Walker Refractories Co., Pittsburgh.

"Molding Sand Tests," by Dr. Richard Moldenke, Watchung, N.J.

Cost Congress.

"Foundry Cost Keeping," address by F. J. Stevenson, cost expert National Association of Stove Manufacturers, Hoosick Falls, N.Y.

"Efficiency in Foundry Operations, the Essential Factor in Reducing Production Costs," address by A. K. Hathaway, Tabor Mfg. Co., Philadelphia.

"Efficiency in Foundry Work," by F. A. Parkhurst, Aluminum Castings Co., Detroit.

"Revision of the A. F. A. Standard Foundry Cost System," by Harrington Emerson, 30 Church Street, New York City.

"Prevailing Practice in Estimating the Selling Price of Castings," by A. O. Backert.

Malleable Iron.

"Manufacture of Malleable Cast Iron," by Harrold Hemenway, H. W. Cooper Saddlery Hardware Mfg. Co., Moline, Ill.

"Test of Malleable Cast Iron," by Enrique Touceda, Albany, N.Y.

"Effect of Silicon and Carbon in Malleable Iron Practice," by A. L. Pollard, Johnston Harvester Co., Batavia, N.Y.

"Malleable Iron Practice," by J. P. Pero, Missouri Malleable Iron Co., East St. Louis.

"Researches in the Annealing Process for Malleable Castings," by Oliver W. Storey, University of Wisconsin, Madison, Wis.

Steel Session.

"The Electric Furnace in the Steel Foundry," by W. L. Morrison, Welland, Ont.

Discussion of Mr. Morrison's paper, by G. J. Stock, Darlington, Eng.

"Making Steel Direct from Ore in the Electric Furnace," by Prof. T. A. Louden, Toronto, Ont.

"Side Blow Converter Practice," by John Gregson, Sivyer Steel Castings Co., Milwaukee.

"Manufacture of Acid Steel for Castings," by A. F. Blackwood, Detroit.

"Notes on the Microstructure of Steel," by Prof. Wm. Campbell, New York City.

"Some Defects in Steel Castings and Remedies for Them," by John Howe Hall, New York.

"Report of the Committee on Steel Foundry Standards," by Dudley Shoemaker, chairman American Steel Foundries, Indiana Harbor, Ind.

Grey Iron Session.

"Cast Iron With Unusual Structure," by K. W. Zimmerschied, General Motors Co., Detroit.

"Elimination of Waste in Bench Molding," by J. C. Pendleton and R. E. Kennedy, University of Illinois, Urbana, Ill.

"Report of the Conservation Congress," by Paul Kreuzpointer, Altoona, Pa.

"Report of the Committee on Industrial Education," by Paul Kreuzpointer, Altoona, Pa.

"Iron and Its Properties," by Peter F. Blackwood, Michigan Steel Castings Co., Detroit.

Green Sand Cores," by James Mulvey, Rensselaer Valve Co., Troy, N.Y.

"Dangers of Specialization," by Thomas D. West, Cleveland.

"Semi-Steel," by R. H. Probert, James Leffel & Co., Springfield, O.

"Tests of Cast Iron," by W. P. Putnam, Detroit Testing Laboratory, Detroit.

"Memorandum on the Preparation of Standard Specifications for Cast Iron for International Export Use," by Dr. Richard Moldenke.

"Industrial Pioneering, or the Establishment of a Foundry in a New Territory," by L. L. Anthes, Anthes Foundry Co., Detroit.

AMERICAN INSTITUTE OF METALS.

AN advance programme covering the 1914 Convention of the American Institute of Metals at Chicago, September 7-11, has been issued by the executive as follows:—

Monday.—Registration.

Monday Evening. — Foremen's banquet, LaSalle Hotel.

Tuesday, 10 a.m.—Joint meeting with the A.F.A. Addresses of welcome.

Tuesday, 2 p.m.—Reports and A. I. M. papers. Both meetings on Tuesday to be held at the LaSalle Hotel.

Tuesday Evening.—Programme open.

Wednesday, 10 a.m.—Joint meeting with A. F. A. Saddle and Sirloin Club. Cost congress. Papers and discussion.

Wednesday, Noon.—Ladies' luncheon at the Stockyards Inn.

Wednesday Afternoon. — Stockyards inspection.

Wednesday Evening.—Open.

Thursday, 10 a.m.—Saddle and Sirloin Club. Papers and discussion.

Thursday, Noon.—Ladies' luncheon, Marshall Field & Co.

Thursday, 2 p.m.—Papers and discussion. Election of officers.

Thursday Evening.—Banquet at the LaSalle Hotel (for members only).

Friday, 10 a.m.—Last session.

FOUNDRY AND MACHINE CO. EXHIBITION.

THE exhibition of foundry equipment and supplies, under the auspices of the Foundry and Machine Co., will be held in the International Amphitheatre, Chicago, from September 5 to September 11, and the following manufacturers have already reserved space for the display of their products:—

Ajax Metal Co., Philadelphia.
Arcade Mfg. Co., Freeport, Ill.
Armstrong-Blum Mfg. Co., Chicago.
Ayer & Lord Tie Co., Chicago.
Berkshire Mfg. Co., Cleveland.
Besley, Charles H., & Co., Chicago.
Blystone Mfg. Co., Cambridge Springs, Pa.
Brown Specialty Machinery Co., Chicago.
Buch's, A., Sons Co., Elizabethtown, Pa.
Buckeye Products Co., Cincinnati.
Carborundum Co., Niagara Falls, N.Y.
Cataract Refining Co., Buffalo.
Central Iron Works, Quincy, Ill.
Chicago Pneumatic Tool Co., Chicago.
Clark, Chas. J., Chicago.
Clark, Jas., jun., Electric Co., Louisville, Ky.
Cleveland Pneumatic Tool Co., Cleveland.
Clipper Belt Lacer Co., Grand Rapids, Mich.
Coburn Trolley Track Mfg. Co., Holyoke, Mass.
Curtis Pneumatic Machine Co., St. Louis.
Dixon, Jos., Crucible Co., Jersey City, N.J.
Edgemont Machine Co., Dayton.
Essley, E. L., Machine Co., Chicago.
Electric Controller & Mfg. Co., Cleveland.
Federal Foundry Supply Co. Cleveland.
Felt & Tarrant Mf. Co., Chicago.
Flexible Steel Lacing Co., Chicago.
Foundry, The, Cleveland.
Garden City Sand Co., Chicago.
Gardner Machine Co., Beloit, Wis.
General Electric Co., Schenectady, N.Y.
Gisbolt Machine Co., Madison, N.Y.
Goldschmidt Thermit Co., New York.
Gould & Eberhardt, Newark, N.J.
Great Western Mfg. Co., Leavenworth, Kas.
Great Western Melting & Refining Co., Chicago.
Hayward Co., New York City.
Henion & Hubbell, Chicago.
Hill-Brunner Foundry Supply Co., Cincinnati.
Hill & Griffith Co., Cincinnati.
Hunter Saw & Machine Co., Pittsburgh.
Independent Pneumatic Tool Co., Chicago.
Industrial Press, New York.
International Molding Machine Co., Chicago.
Iron Trade Review, The, Cleveland, Ohio.
Janesville Wisconsin Molding Sand Co., Janesville, Wis.
Kawin, Chas. C., Co., Chicago.
King, Julius, Optical Co., New York City.
Lupton's, David, Sons Co., Philadelphia.
McCormick, J. S., Co., Pittsburgh.
McLain's System, Milwaukee.
MacLeod Machine Co., Cincinnati.
Midland Machine Co., Detroit.
Monarch Engineering & Mfg. Co., Baltimore.
Norma Co. of America, New York.
Norton Co., Worcester, Mass.
Obermayer, S. O., Co., Chicago.
Osborn Mfg. Co., Cleveland.
Oxweld Acetylene Co., Chicago.
Pangborn Corporation, Hagerstown, Md.
Paxson, J. W., Co., Philadelphia.
Peerless Parting Co., Ottawa, Ill.
Picklands, Brown & Co., Chicago.
Pridmore, Henry E., Chicago.
S. K. F. Ball Bearing Co., New York.
Sand Mixing Machine Co., New York.
Shepard Electric Crane & Hoist Co., Montour Falls, N.Y.
Sly, W. W., Mfg. Co., Cleveland.
Smith, R. P., & Sons Co., Chicago.
Sterling Wheelbarrow Co., West Allis, Wis.
Stevens, Frederic B., Detroit.
Sullivan Machinery Co., Chicago.
Superior Oxygen Co., Pittsburgh.
U. S. Graphite Co., Saginaw, Mich.
Vulcan Engineering Sales Co., Chicago.
Wallace, J. D., Chicago.
Warner & Swasey Co., Cleveland.
Westinghouse Electric & Mfg. Co., East Pittsburgh, Pa.
Whiting Foundry Equipment Co., Harvey, Ill.
Wilmarth & Morman Co., Grand Rapids, Mich.
Wood's, T. B., Sons Co., Chambersburg, Pa.
Wyoming Shovel Works, Wyoming, Pa.

DARK GREEN GOLD FINISH.

A DARK green gold can be made in the following manner:—

Cyande of potash	3 oz.
Pure silver to be made into chloride	¼ oz.
Pure gold to be made into chloride	¾ oz.
Water	1 gal.

Use hot with a gold anode composed of three parts gold and one part silver. This solution will give you a green deposit. In order to get a dark green, make up a solution of:

Water	1 gal.
Caustic potash	1 oz.
White arsenic	½ oz.

Boil together, then add a few drops of this solution to the above green gold solution until you get the desired color.

Metal Statistics.—Coincident with the announcement of the members of the New York Metal Exchange that that institution would discontinue operations until further notice, the Copper Producers' Association on August 4 announced that the usual monthly statement of copper production and stock on hand would be omitted because of the mixed conditions of the copper market.

PRODUCTION METHODS AND DEVICES

A Department for the Interchange and Distribution of Shop and Office Data and Ideas Evolved from Actual Practical Application and Experience

TURRET LATHE AND VERTICAL BORING MILL PRACTICE.—III.*

By Albert A. Dowd.

PARTS I. and II. of this series of articles dealt with the first and second settings and sequence of operations relative to the machining of the

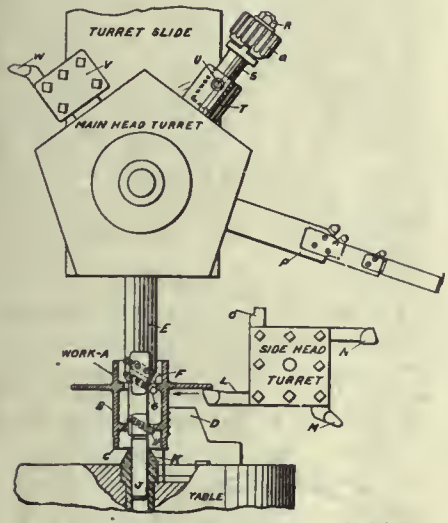

FIG. 5. FIRST OPERATION — FIRST SETTING.

rear hubs of an automobile on the vertical turret lathe. The present and succeeding article discusses the procedure adopted in machining a front hub.

Machining a Front Hub on the Vertical Turret Lathe.

We shall now take up the machining of a front hub in which the bearing seats at the two ends must be in perfect alignment with each other. The work A shown in Fig. 5 is of malleable iron and is held by the outside of the hub B in the special laws D. These jaws are provided with a shoulder against which the end of the hub C locates, thereby obtaining uniform vertical position. A hardened and ground tool steel bushing is fitted to the center hole of the table and acts as a guide for the piloted ends of the boring bars.

Attention is called to the fact that the upper end of the bushing is of conical shape, so that any chips or dirt falling on it will have a tendency to slide off on to the table. The boring bar E is of .040 carbon steel and is piloted at its lower end J in the bushing K. This pilot is carbonized, case-hardened and ground to a running fit. Three high-speed tools F, G, and H are angularly placed in the bar and are provided with backing-up screws so that fine adjustments may be readily made for diameters.

The finishing bar P is identical in construction with the roughing bar, and the tools are set for the finishing cut, making due allowance for the reaming cut in the bearing seat. The reamer Q is of high-speed steel and is finished with a taper hole which fits the conical stem on the arbor S, a suitable driver being provided as shown in the illustration. The nut B holds the reamer firmly on the arbor. The steel holder T is securely clamped in the turret hole and the pin U acts as a driver for the reamer arbor. Clearance is provided in the hole so that the reamer may float and follow the generative hole produced by the boring bars. A standard tool holder V contains a finish facing tool W of high-speed steel. The tool L in the side head is used for rough undercutting the flange, while that at N is the finishing tool for the same surface. A rough turning tool at M and a corner rounding tool at O complete the side head turret tooling.

Sequence of Operations—First Setting.

First operation:—The tools shown in cutting position on the work in Fig. 5 are used for the first operation, which is that of boring the bearing seat and the two inner clearance holes with the main head. During the operation of these tools the undercutting tool L in the side head rough faces the under side of the flange. The purpose of boring the two inner clearance holes is to make sure that the required clearance is obtained at these points, and in the case of the lower and smaller of the holes, the bored surface is used in the second setting of the work.

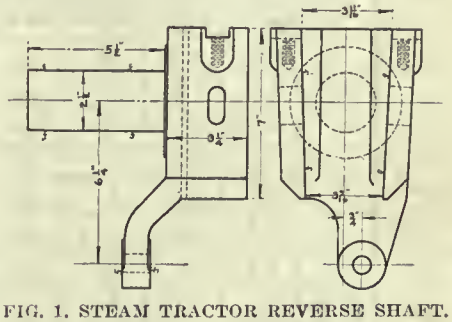

FIG. 1. STEAM TRACTOR REVERSE SHAFT.

Second operation:—Fig. 6 shows the remainder of the operations in the first setting of the work. The second operation consists of finish boring the interior surfaces previously rough bored in the first operation, the boring bar P being used for this purpose. While this operation is taking place, the side head is used to face the end of the hub and trim up the outside of the flange, the tool M being brought into play for the work.

Third operation:—Immediately after the second operation of boring has been accomplished, the rapid power traverse on the machine is started to withdraw

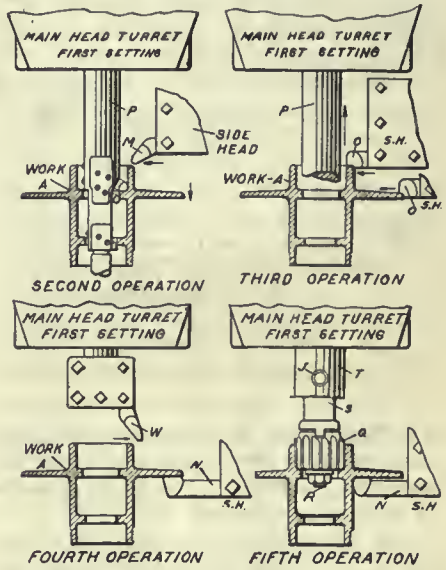

FIG. 6. REMAINING OPERATIONS — FIRST SETTING.

the bar from the hole, and the tool O in the side head is brought up against the flange and end of hub and used to break the corners. Very little time is lost by this method of procedure.

Fourth operation:—The finish facing tool W is now used in the main head turret to face the end of the hub, and the finish undercutting tool N in the side head takes a light finishing cut with a coarse feed on the under side of the flange.

Fifth operation:—Before the side head has finished its work, the floating reamer Q in the main head is indexed into position, the speed of the machine slowed down and the hole reamed to size. This completes the first setting of the work.

AN INDEXING MILLING FEATURE.

By A. S. Loy.

THE casting shown in Fig. 1 was used as the reverse shaft on a well-known make of steam tractor. This piece has two internal faces milled at a taper with respect to each other, being 3 11-16 inches apart at the one end and 3 3-16 inches at the other. Each of these faces is provided with a steel taper key so that the insides come parallel for a sliding wooden block. Studs are placed in

*Parts I. and II. of this series appeared in our July 30 and August 6 issues.

the tapped holes shown, and the tapered keys provide a ready means of adjustment.

The first operation on the piece was chucking and turning the 2½ inch leg. The tapered sides were then shaped in as correctly as possible, and the keys which had previously been milled on the one side were then fastened in place and

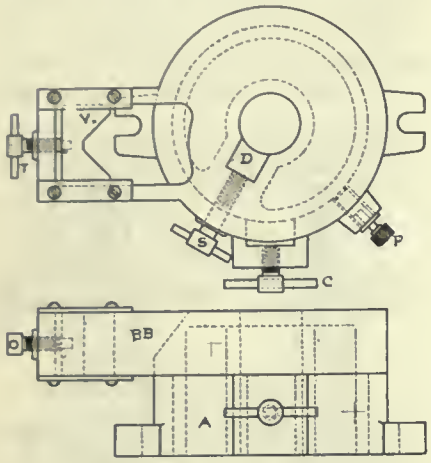

FIG. 2. INDEXING MILLING FIXTURE.

a milling cutter of the proper width run through them. This did not make for interchangeability and a great number of complaints resulted.

The fixture shown in Fig. 2 was then designed for milling the sides and producing duplicate parts. The base A was provided with keys to fit the miller table slots and was bored out to receive the table B which was clamped in the base by the screw C. The index pin P located the table at the proper angle. The reverse shaft was dropped into the hole in the center of the table, and the V-block run up by means of the screw T against the round boss at the one end. The shaft was clamped in the table by the screw S, which pushed up the piece D, bearing along the full length of the leg. A milling cutter was set at the proper distance from the center of the fixture so that, by indexing the fixture nearly halfway around, both faces could be milled with the one setting.

PISTON RING DATA.

By D. O. Barrett.

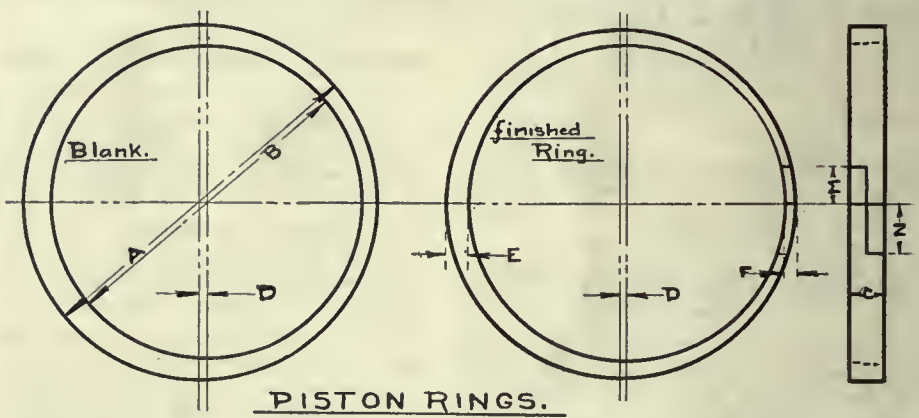
PROBABLY there is no part of a gasoline engine upon the design of which there is such a lack of accurate knowledge as the piston ring. Most piston rings are the result of hit-and-miss design, or are merely copies of some competitor. Of course, a properly proportioned piston ring for any particular engine can only be determined after long experimenting and trials under actual conditions. There are, however, a few points which, if understood, would make the calculation of piston ring sizes somewhat easier for the average man.

Piston rings may be turned either concentric or eccentric, each style of ring having its advocates, but, in general, nearly all manufacturers return their rings to the piston diameter after first having split them. The amount left for the returning is usually about 1/32 of an inch. For stationary horizontal engine work, the lap joint requiring two cuts is almost universally adopted. The amount to be cut out of a ring to give the proper amount of tension when in the cylinder is another matter of experiment. For the sake of example, let us say that the amount to be taken out of a lap joint ring is 5/8 inch, and the bore of the cylinder is 6 inches.

The circumference of the cylinder bore will measure 6×3.1416, or 18.850 ins., and the circumference of the ring before splitting will be 18.850+0.625, or 19.475 ins., which corresponds to the diameter of 19.475÷3.1416, or 6,199 ins. Let us assume that 1/32 inch has been left for returning; then the diameter of the ring blank before splitting should be 6.199+0.031, or 6.230 ins. The diameter of the returning fixture for holding the rings while clamping, would of course, be about 6 1/32 inches. However, since in splitting the rings the sides of the cut are parallel, the edges only of the split will meet when the ring is closed together, necessitating a small amount of filing to bring both edges radial. The ring blanks will, therefore, have to be slightly larger than 6.230, or allowing 0.02 for filing, the diameter will be 6¼ inches. In actual practice the diameter of the returning fixture is obtained by trial, fitting a ring by filing the edges to the proper fit before inserting. No fitting will then be necessary after the rings are returned for the bore of the cylinder.

The accompanying table gives the piston ring practice of one of the large companies building gasoline engines. One side of the ring was cut with a 5/8 milling cutter and the other side with a 7/8 cutter. This left a ¼ inch opening on one side when the ring was closed together for a pin in the slot to prevent the movement of the ring around the piston. The blank diameters were made ¼ inch larger than the bore diameters, leaving slightly more than 1/32 inch for returning.

The ordinary practice of dimensioning a finished ring is to be deprecated. The dimensions for turning and boring the blanks should be given on a drawing of the blank, shown separate from the drawing of the finished ring itself.



PISTON RINGS.

Bore of Cylinder.	Ext. Diam Blank. A.	Int. Diam Blank. B.	Width of Ring. C.	Eccentricity. D.	Thickness. E.	Thickness. F.	Returned Diameter.	Cutter for M.	Cutter for N.

THE COLLEGE GRADUATE.—III.*

By D. S. Mann.

A GOODLY number of graduates, upon leaving school, depend upon their instructors or department heads to locate positions for them and in most cases these men are always glad to recommend them. However, would it not be infinitely better for a man, after graduation, to break loose from the ties which have bound and restricted his thoughts and activities for four years and to actually hunt for a job himself. Would not the job carry with it a greater sense of responsibility under these conditions? The man who depends upon another to locate and choose a position for him is in the same class with the man who lets some one else prepare his lessons for him. He has missed an opportunity to show the world that he can stand on his own feet. The writer recently saw an adage to the effect that a man who has made a success in business was only justly entitled to credit if his business had been a competitve one. The commercial world is practically summed up in the one word, competition, and the fact must not be lost sight of that business enterprises are operated in order to pay the stockholders a profit on their money invested and not merely to provide a lot of convenient openings for men who are looking for high-salaried positions with cane-seated chairs and eight-hour days.

The writer has always contended and has conducted himself along these lines: that a man gets or will get, if he has any ambition, just exactly what he is looking for and (most important of all), what he is prepared for. All one has to do to prove to his own satisfaction that positions of trust and responsibility are open is to look through the want columns of our engineering journals. The majority of these call for trained men and our colleges do not make any pretence of turning out specialists. A man who takes the average college course certainly deserves a lot of credit for the time and energy which he has expended but he must not let his energies flag in the least, in fact, the hardest part is before him, for he must now get out and, furthermore, produce in competition with men who are trained along these particular lines. He has now to devote himself to whatever line of work he has undertaken and proceed to make himself a specialist and he must concentrate all his efforts and know no limiting hours.

*Parts I. and II. appeared in our issues of July 30 and August 6, respectively.

The letter of John Fritz to Dr. Goss which was published after his death should certainly be an inspiration to college men who have had the preliminary training which he, however, was not fortunate enough to have. It is certainly high time that our colleges woke up their students and put some life into them outside of that engendered by their studies and, perhaps, athletics. To do this it would probably be necessary to plant some tacks in the cushions of some of our college professors' easy chairs. How is it that we expect to turn out $10,000 a year men under the tutelage of $2,000 instructors? If these positions are available, why are there not more instructors leaving the schools and accepting these for which they should be most admirably fitted?

Writing to Technical Journals.

The writer supplies considerable material to several technical journals and is in receipt of letter after letter asking for the names of parties who can write on various subjects. Numerous college men, both freshly graduated and with several years' experience, have been approached, but they have all expressed the opinion that they were unqualified for this work. This would hardly seem possible when all college courses contain a period devoted to English literature. How many practical men are there whose methods of expression are exceedingly raw, yet these self-made men bring forth ideas that prove to be wonderful time-savers and money-makers and, after all, is it not ideas which really count? Does the college man who thus readily acknowledges his incompetency as compared to the average man without his education reflect any credit either on the institution which matriculated him or upon himself?

Only one professor during the writer's college career, and he has already been mentioned, ever brought to mind that any such opportunity existed. While it is perhaps tedious work for some, and whether the remuneration is ample or not is a somewhat debatable question, yet the experience gained is exceedingly valuable and more than repays any extra effort exerted. A man's vision is broadened, his method of expression improved, and he is brought into contact with other men in such a way that only good can result. During the course in English would it not be a good plan to assign a subject to the class for a theme and, picking out the most valuable of these, to send them to some magazine for publication. Such a method as this would stir up interest in a course in Englsh which at present is almost an impossibility in an institution devoted to engineering studies.

It would also seem a wise provision in our colleges to insist upon, or better perhaps, add as an integral part of the four-year course, two or three months actual shop or drafting room experience during the summer vacations. A man would come back in the fall with a better idea of just the sort of preparation necessary, and would see the benefit of some portions of the course and perhaps the folly of some others. The writer is willing to express his belief that those schools which have the most practical work incorporated into their courses, both in the shop as well as the laboratory, turn out the best men, at least men who are able to go out and hold their own. A man coming directly from school is suddenly thrown into an entirely new atmosphere and he quite naturally sees things in a different light from those who have been actually engaged in the work for some time; but that is no reason why he should immediately suggest a lot of impossible reforms which do not do his good judgment any credit. Perhaps many of these have already been tried or for some particular reason are not feasible in the line of work.

With some sort of a preliminary practical training, much of this would be brought to his mind, and he would not feel hurt the first time some of these visionary methods are proposed to those in authority and turned down. Any firm is willing and glad to receive suggestions from their employees which will enable them to decrease the cost of manufacture of their product, or will enable them to increase their efficiency in any way.

The writer may, perhaps, have some radical views on the subject, but is guided entirely by his experience and observations and of those with whom he has come in contact. As industrial conditions change and become more and more competitive, so should our methods of education change, and men should be prepared for the conditions as they find them. It should hardly be necessary for a man, after putting in four or five years at college, to put in three or four more in order to become conversant with any one line of work. Our colleges must wake up to the fact that much is expected of them, and that their development is being keenly watched by those less fortunate, and any disappointing results throw a light upon this kind of an education.

Arithmetic for the Machinist and Workshop Operative

By J. H. Rodgers

With the further development of this course in arithmetic. it will be found by those who have followed the introductory lessons and profited by them that the various practical applications resulting from the succeeding lessons will be easily observed and their time and labor-saving features so appreciated as to be adopted at every available opportunity.

FEEDS.

NO doubt the adjustment of cutting tools for machining jobs in different machine tools in the shop is in large degree a matter of guesswork on the part of the operator, and where this guesswork on the mechanics part is derived from much experience, the adjustment of the tools or tables becomes very accurate; but when young and inexperienced men are adjusting the lateral or vertical feed of a tool or table, the proper adjustment will in most cases be only a matter of chance. To help overcome this failing to some extent, and instill the practice of using figures in work where their application obviates to a large degree the guesswork of the shop, a few practical examples are here given.

In chart 31 is shown a skeleton sketch of the cross feed of a lathe. A piece of work W requires 3-16 in. of metal removed in two cuts, the finishing cut to reduce the diameter 1-32 of an inch.

The roughing cut must remove 3-16 in. —1-32 in.=5-32 in. of metal, or the cutting tool must advance into the work 5-32 in.÷2=5-64 of an inch.

The cross feed has 6 threads per inch, and the graduated disc has 50 divisions.

The general way (and possibly the best one) would be to follow up the cut with a pair of calipers set to the required diameter, but as this series of lessons is for the purpose of showing the usefulness of calculations in the general run of shop problems, an approximate method of determining the proper adjustment of the tool may prove of some benefit to those who have been formerly taking a chance.

Most lathes or other machine tools of modern make usually have a graduated disc placed on parts of the machine where micrometer adjustment is desirable. In the cut, chart 31, (a) represents the graduated disc, (S) the cross feed screw, (t) the cutting tool and (W) the work. To find the lateral feed (F) we divide the number of divisions moved on disc (a) by the total number of divisions (d) on disc (a), and multiply by the pitch of the cross feed screw (S), or by formula.

$$F=\frac{M}{d}\times p,$$ or to find the movement of (a), use formula $M=F\times d\times n$.

To solve the above question, the required result is the number of divisions to move the disc (a) to remove 5-32 of an inch in diameter.

$$M=F\times d\times n=\frac{5}{64}\times\frac{50\times 6}{1}=\frac{375}{16}=23\ 7\text{-}16 \text{ divisions.}$$

For finishing cut of 1-64 in. deep.

$$M=\frac{1}{64}\times 50\times 6=\frac{75}{16}=4.68,$$ or a little over 4½ divisions. These solutions are only as a guide to approximate adjustment; accurate sizes must always be determined by the calipers or micrometers.

It is required to remove 3-32 inch of metal from a block of steel, the feed screw in the shaper head having a pitch of 1-6 inch or 6 threads per inch, and the graduated disc being divided into 80 divisions. What movement of the feed screw is required?

By formula chart 31

$$M=F\times d\times n=\frac{3}{32}\times\frac{80\times 6}{1}=45 \text{ divisions.}$$

In the foregoing example, if the feed screw had been revolved one turn and 15 divisions, what would have been the depression of the tool?

By formula chart 31

$$F=\frac{M}{d}\times p=\frac{95}{80}\times\frac{1}{6}=\frac{19}{96},$$ or expressed in the nearest 64th.

$$\frac{19}{96}\times\frac{64}{1}=\frac{38}{3}=12\ 2\text{-}3 \text{ or } 13\text{-}64 \text{ inch.}$$

In chart 32 is shown an arrangement, often seen on machine tools whereby the movement of the handwheel is transmitted to the feed screw through a pair of bevel gears. These gears may be of equal size or a pinion and a gear, thus compounding the movement of one shaft with the other. A general formula for adjustment of cut is given in chart 32.

$$M=\frac{N\times G\times D}{P}\times E,$$

$$\text{or } E=\frac{M}{\frac{N\times G\times D}{P}}, \text{ where}$$

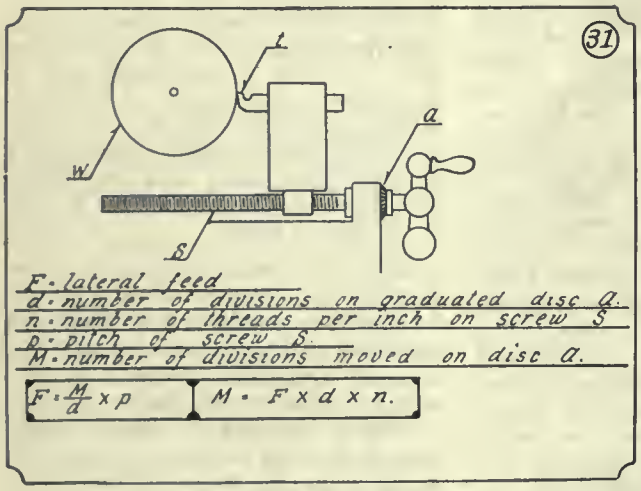
M=number of divisions moved on disc (a).

N=threads per inch on screw (S).

d=number of divisions on graduated disc (a).

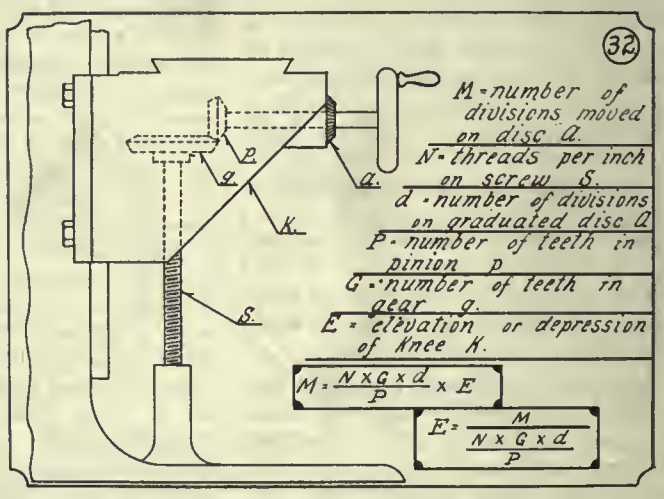
P=number of teeth in pinion (p).

G=number of teeth in gear (g).



31
t
a
W
S
F - lateral feed
d - number of divisions on graduated disc a.
n - number of threads per inch on screw S
p - pitch of screw S.
M - number of divisions moved on disc a.
F = M/d x p
M = F x d x n.

ARITHMETIC CHART 31.



32
M - number of divisions moved on disc a.
N - threads per inch on screw S.
d - number of divisions on graduated disc a
P - number of teeth in pinion p
G - number of teeth in gear g.
E = elevation or depression of knee K.
p
g
a.
K
S
M = N x G x d / P x E
E = M / N x G x d / P

ARITHMETIC CHART 32.

E=elevation or depression of knee (k).

The elevating screw on a milling machine has a pitch of 1-5 inch or 5 threads per inch, the graduated disc (a) has 100 divisions, ratio of the bevel gears is 2 to 1, and the pinion is on the horizontal shaft. What movement will the knee (k) have if the handwheel is revolved one turn and 40 divisions?

By formula

$$E = \frac{M}{\frac{N \times G \times d}{P}} = \frac{140}{\frac{5 \times 2 \times 100}{1}}$$

$$\frac{140}{5 \times 2 \times 100} =$$

7.50 in. or expressed as a decimal=.149 in.

In the above example, the ratio of the gears was used instead of the number of teeth, but the result would be the same, as 2:1 or 30:15 or 48:24, etc., would answer the same purpose when figuring, as definite sizes are not essential.

If, in the above problem the adjustment vertically was required to be .375 in., what would be the movement of the disc (a)?

By formula

$$M = \frac{N \times G \times d}{P} \times E = \frac{5 \times 2 \times 100}{1} \times .375 =$$

$$\frac{375}{100} = 3$$ turns and 75 divisions.

If the adjustment required were 7-64 inch.

$$M = \frac{N \times G \times d}{P} \times E = \frac{5 \times 2 \times 100}{1} \times \frac{7}{64} =$$

109⅜ divisions, or one turn and 9⅜ divisions.

In a certain small die slotter the bevel gears are completely hidden, the screw (S), chart 32 has 6 threads per inch, and the graduated disc (a) has 50 divisions. If each division represents an elevation or depression of the knee (k) equal to .001 of an inch, what is the ratio of the two gears (p) and (g)?

By formula

$$M = \frac{N \times G \times d}{P} \times E \text{ or}$$

$$\frac{G}{P} = \frac{M}{N \times d \times E} = \frac{1000}{6 \times 50 \times 1} = \frac{10}{3}, \text{ or } \frac{40}{12} \text{ or } \frac{50}{15}$$

Collingwood, Ont.—The management of the Imperial Wire Company state that they hope to start the entire plant almost immediately. For some time the keg mill has been in operation and this will be continued.

Questions and Answers

FOUNDRYMEN having difficulties of any kind in connection with their work are invited to forward them to this department for solution. The causes of lack of success in the foundry are of such variety that one man cannot possibly succeed in mastering them all. The greatest possible care will be taken to give only reliable and tried out advice on all questions submitted.

Light Casting Trouble.

Question. — We are having much trouble in getting sound castings in certain lines of work. Our coke is low in sulphur, and, as our castings are very light we are using iron with the silicon running up to 3 per cent. We have also used chills, but do not get satisfactory results.—A. O. B.

Answer.—Iron containing 3 per cent. of silicon is only suitable for very light castings, such as light hardware, and will give trouble in those of any size. Have your moulds well vented and use skim gates. Get some ⅜ or ½ inch rod aluminum and melt a piece about 1 inch long in 75 lbs. of metal. This aluminum is pure and will unite with the gas to form dross and thus eliminate it.

Large Cylinder Mixture.

Question.—Will you kindly give an analysis for a first-class heavy cylinder mixture?—T. R. W.

Answer.—A most suitable mixture for this purpose would contain: Silicon, 1.20 to 1.40 per cent.; sulphur, 0.09 per cent.; phosphorus, 0.35 to 0.50 per cent., and manganese, 0.50 to 0.80 per cent. The transverse strength of a test bar 1 inch square by 12 in. long should not be less than 2,600 lbs., and the tensile strength per square inch should be at least 24,000 lbs. per square inch.

Shrink Holes in Aluminum

Question.—We are making aluminum castings and would like to know how to overcome shrink holes which give us considerable trouble.—D. S.

Answer.—There are several causes for shrink holes in aluminum. There may not be enough feeders or they may not be large enough. The moulds are often rammed too hard or the casting may not be gated in the proper places. The constitution of the metal itself is often the greatest cause of the trouble. If some copper be used in the alloy and the zinc content be decreased as much as possible, the shrink holes will be less numerous. If ingot aluminum is being used, the trouble is not likely to be in the metal, and can be overcome by proper feeding and the use of chills on the heavy points.

Flux for Brass.

Question.—Please furnish us with what you would consider a reliable flux for brass.—T. G. Co.

Answer.—Common salt is the cheapest and best flux for brass. Put it in the crucible at the beginning of the heat in the proportion of about a small handful to 100 pounds of metal.

Light Malleable Mixture.

Question.—Will you give the chemical composition of first-class malleable iron for light hardware castings?

Answer.—A good mixture for this purpose will contain: Silicon, from 0.80 to 1.25 per cent.; sulphur, not over 0.05 per cent.; manganese, not over 0.25 per cent., and phosphorus not over 0.20 per cent. The carbon must not run below 2.75 per cent. and the silicon should be kept as near the lower limit as possible.

Plumbers' Ferrules.

Question.—We would like to know of a good cheap mixture for making brass ferrules for plumbers.

Answer.—A very much used composition for this purpose is made up of copper, 53 lbs.; zinc, 41 lbs. 10 ozs.; lead, 5 lbs., and aluminum, 6 ozs. This is a good fluid mixture, and you will have no difficulty in running any size ferrule.

Question.—Will you kindly tell me what treatment should be given acid burns of the eyes?—J. B.

Answer.—If clean warm water be obtainable, it should be applied immediately and liberally. Follow with application of sweetmilk, allowing the liquid to flow freely over the eyeball. After the milk and water washing, warm a few drops of cocaine hydrochloride and apply to the eye, and then apply a little castor oil; next saturate a small piece of absorbent cotton with warm water and bind over the eye with a light bandage. This cotton should be renewed frequently. The cocaine hydrochloride may be warmed by putting a few drops in a teaspoonful of hot water. If the burn be a bad one, and the eye becomes inflamed, use an ointment at bedtime consisting of vaseline and 2 per cent. cocaine hydrochloride. Burns of the eye resulting from potash or hot cyanide copper solution should be immediately washed with clean cold water and then bathed with a strong solution of boracic acid. This treatment will relieve the soreness and avoid inflammation, which would otherwise cause the eye to become very troublesome.

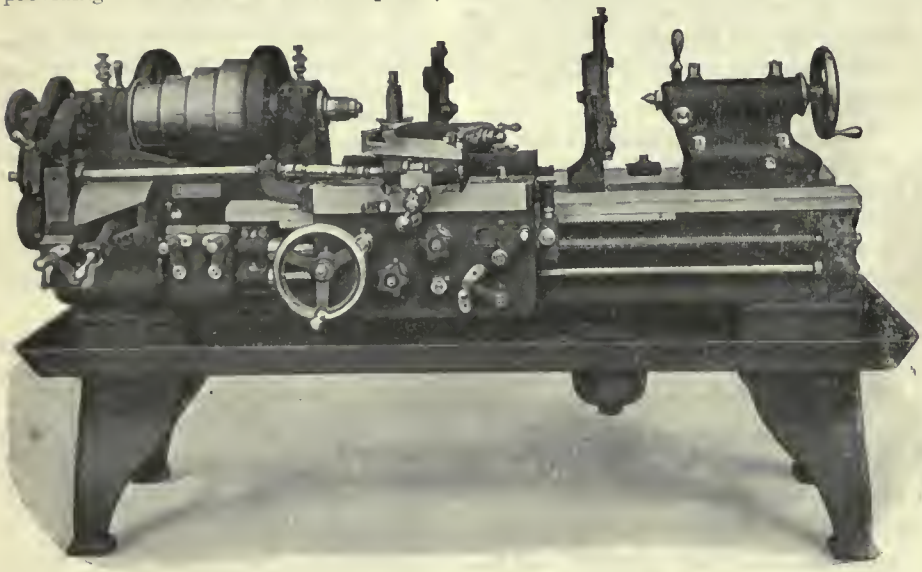
PROGRESS IN NEW EQUIPMENT

A Record of New and Improved Machinery and Accessories for the Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

"AMERICAN" TOOL ROOM LATHE.

THE 14 in. x 6 ft. lathe, with complete tool room equipment, described and illustrated herewith, is a product of the American Tool Works Co., Cincinnati, Ohio, and was supplied through the manufacturers' agents (Rudel-Belnap Machinery Co., Toronto and Montreal) for tool room work in the Toronto plant of the S. F. Bowser Co.

This lathe has a patented type of bed providing what is known as a drop vee; that is, the inner or tailstock vee is dropped below the level of the outside vee. The construction provides greater swing over the bed than the rated swing of the lathe, viz., 15¼ inches. Probably, however, the greatest advantage of the patented bed construction is that it permits the use of a very deep carriage bridge, thus greatly strengthening the machine at that point, and thereby eliminating the possibility of chatter. It should also be noted that the ways of the bed are chilled, offering a very hard, close grained surface to the carriage bearings, which, being less subject to wear, confines whatever wear that does take place to the carriage bearings, where it will not effect the alignment of the machine. The chilled ways also prevent the bed from wearing hollow; consequently, it will hardly be found necessary to resort to replaning to regain the original alignment.



14 IN. X 6 FT. AMERICAN TOOL ROOM LATHE.

It is further to be noted that the quick change gear mechanism fitted is particularly adapted to tool room work, for not only does it provide a wide range of threads and feeds, but it is so designed that special threads can be cut when desired by simply making a slight change in the gearing of the back quadrant, very similar to the change required on a loose change gear lathe to cut different threads. This feature provides practically an unlimited range for the lathe, consequently the machine need never be found wanting in any emergency. All gears in this mechanism are steel, the cone and tumbler gears being cut with 20° B. & S. cutters, producing a tooth of wide section at the base and pointed at the top. Both lead screw and feed are furnished, all threading operations being confined to the lead screw and all feeding operations to the feed rod. This tends to insure greater accuracy and longer life to these members than when only a splined lead screw is provided, which is called upon to do both the feeding and threading.

The apron is of substantial design, being of the box type with a back plate, giving all studs a double support, and thus eliminating all overhang. All gears are cut from bar steel with the exception of the large friction gear, which is a steel casting, and every bearing is hushed with a renewable phosphor bronze bushing and is provided with efficient means of lubricating. Oil reservoirs are cast in the back plate of the apron, into which the oil is led by means of gravity through pipes from the front. Oil ducts lead the oil from the reservoirs to the various bearings, and over each duct a strip of felt is placed, which filters the oil and insures a good, clean lubrication at all times, and also regulates the flow of the oil and prevents waste.

Probably the most important and desirable feature for tool room work, however, is the extreme accuracy claimed. This machine is positively guaranteed to work within .001 of an inch in 24 inches. The workmanship of this lathe is also fully guaranteed to be of the very best that intelligent effort, combined with long experience, skilled workmen and a complete jig and tool system can produce, likewise a positive guarantee is given of every piece of metal entering into construction.

A 12-IN. PRECISION GRINDER.

IN the accompanying cut a 12-in. precision grinder recently put on the market by the C. G. Garrigus Machine Co., of Bristol, Conn., is shown. The feature in this grinder wherein it differs from most grinders, lies in the fact that it operates on the rotary principle instead of the reciprocating. This, of course, increases the speed with which work can be done over that of the reciprocating types. The limit of the machine is a casting that comes within a circle of 12 in. diameter, and is not thicker than 8 in. It is claimed by the manufacturers that the machine will grind to within .0004 in. of accuracy.

A 12-IN. PRECISION GRINDER.

The head is supported on a vertical oscillating column 41 in. long. This column is attached to the feed shaft which receives its motion from a pawl and ratchet. One tooth movement of the ratchet wheel lowers the head .000125 in. A magnetic chuck is mounted on a spindle, which is operated by a cone clutch pulley and connected by gearing to the cam which operates the wheel column. The amount of oscillation is regulated by the adjustment of this cam roll. Throughout the machine, the bearings are amply large for all requirements, and in the wheel column the construction is such that slight wear in the bearings does not appreciably effect the accuracy of the machine.

The lever controlling the movement of the head and the rotation of the clutch is situated at the side of the machine.

A NEW STARTING UNLOADER.

TO maintain a uniform pressure in the receiver and pipe lines, and to prevent the engine or motor driving the air compressor from stalling through overload,

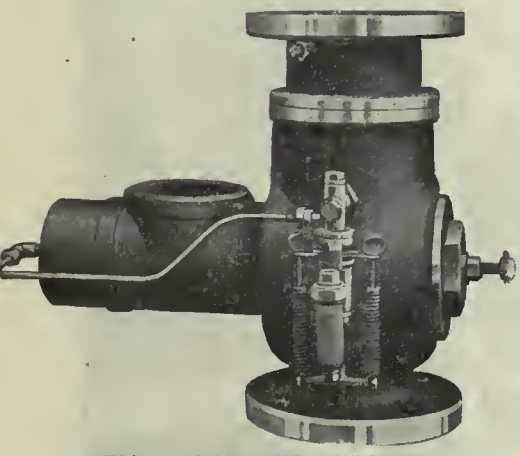


FIG. 1. STARTING UNLOADER.

it is essential that the compressor, whether steam, gas or motor-driven, be provided with some device that will unload it, when the desired receiver pressure is attained, and start the air into the receiver again when the pressure has fallen but a small amount below maximum or any predetermined point.

An interesting starting unloader for motor-driven compressors, in which the motor current is cut out or in to stop or start the compressor when a maximum or minimum load is reached, has recently been added to the field of air controlling devices by George M. Richards, formerly of Erie, Pa. In this latest apparatus the unloading action is obtained by the velocity of the air pressure passing through the chamber and the variation of the receiver pressure. The compressor is completely unloaded when speed is reduced about 25 per cent., and by this action any recoil on the last revolution experienced when stopping against a load is obviated.

When the motor starts the air is by-passed to the atmosphere, until the desired speed is obtained, at which point

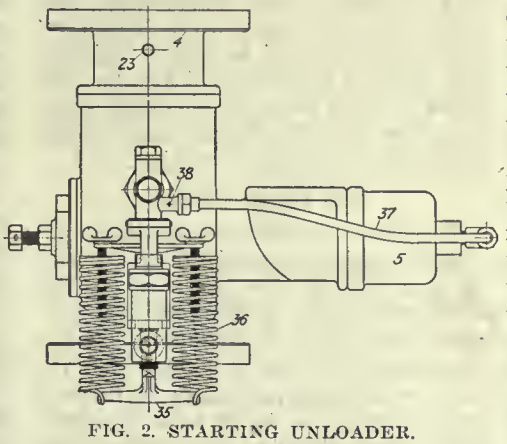

FIG. 2. STARTING UNLOADER.

the by-pass valve closes and the air passes to the receiver until the predetermined pressure at which current is cut out is reached. Then the by-pass is opened by the receiver pressure, via the trigger, against the unloading piston. The intake air has then, with the compressor unloaded, a practically free passage through the cylinder, with resultant cooling effect until the machine stops. The different loading and unloading operations are dependent upon the speed of the machine, and, therefore, entirely automatic. When the current is cut out and the compressor slows down, the by-pass valve opens automatically and unloads before the compressor stops. When the current is cut in, compression does not occur until the motor has obtained the desired speed. The principal advantage claimed for this new unloader is the fact that a compressor equipped with it will require very much less power to start it. Such a compressor can, therefore, be driven by a motor of much less

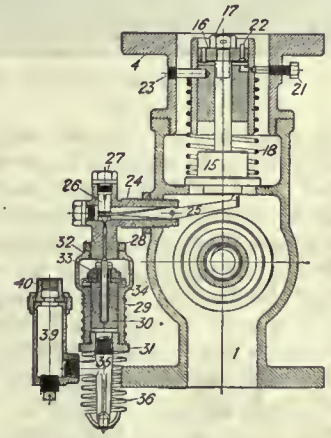

FIG. 4. STARTING UNLOADER.

power than ordinarily used. The operating parts of this new unloading device are few and simple, and consist of a by-pass valve (3), a check valve (15), unloading piston (6), and trigger (35). The detailed operation in connection with Figs. 2, 3 and 4 is as follows:—

Operation Features.

The air from the discharge port of the compressor enters at the bottom of the unloader and passes through the open valve (3), Fig. 3, to the atmosphere until the by-pass valve (3) is closed by the velocity overcoming the tension of spring (10). It then lifts check valve (15) and passes to the receiver connected to the top of the unloader. Check valve (15) is controlled by dash pots (16) and (19) to prevent its seating at every stroke; the time of seating being regulated by vent screw (21), Fig. 4. The small valve (22) is a vacuum breaker to allow the check valve to lift freely, while (23) is a fixed pin for holding the dash pot bushing in place.

The receiver pressure to operate the trigger mechanism enters trigger cylinder (29) through port (40) and filter (39), Fig. 4, and constantly acts on piston (30) to close bleeder valve (32), and closes valve (32) when pressure is within 3 lbs. of the maximum. As soon as the motor current is cut out and the speed is reduced about 25 per cent., the

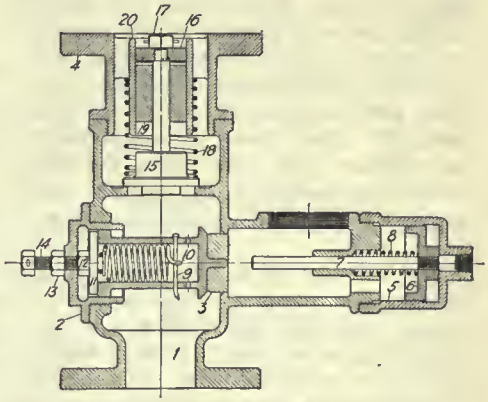

FIG. 3. STARTING UNLOADER.

check valve (15) seats and presses down lever (25) and lifts pilot valve (26), admitting pressure from chamber (1) through tube (37), Fig. 2, behind piston (6). Fig. 3 in cylinder (5), and by-pass valve (3) is forced open by piston rod (7), Fig. 3.

When the receiver pressure has dropped about 3 lbs., or any predetermined amount, tension springs (36), Fig. 2, pull down the trigger piston (30), Fig. 4, and bleeder valve (32). After starting again and the velocity has closed by-pass valve (3), the accumulating pressure in the valve chamber (1) blows out of the pilot valve (26) and bleeder valve (32) until check valve (15) lifts and lever (25) releases pilot valve (26) and allows it to close. The tension on springs (36) is usually so adjusted that the pressure under piston (30) closes bleeder valve (32) when within 3 lbs. of maximum and opens the valve when the

pressure has dropped about 3 lbs. In order to prevent any possible leakage past pilot valve (26) from acting on piston (6) and forcing by-pass valve (3) open a minute hole is drilled at (38), Fig. 2, to permit this air to escape.

Just before unloading occurs the bleeder valve (32), Fig. 4, closes and allows the full pressure to act on piston (6). While loading it is kept open to prevent the pressure from acting on the piston. The baffle washer (34) is to prevent cylinder oil which may blow out of the bleeder valve from coming in contact with piston (30).

The unloader is generally placed on the discharge port of the compressor cylinder, but may be placed anywhere in the discharge line near the cylinder, and efficient operation will not be hindered. The adjustment of the unloader to the required condition of the compressor is particularly simple. When the compressor is near the desired speed, lock nut (13) is backed away and thrust screw (14) is turned in, thus moving by-pass valve (3) towards its seat till it closes automatically by the velocity of the escaping air, then the lock nut is set up. When the receiver pressure is within about 3 lbs. of the maximum or cutting out point, then springs (36) on the trigger are so adjusted that the pressure under piston (30) closes bleeder valve (32), and, conversely, opens the valve when the pressure has dropped the same amount. After these two single spring adjustments have been made, the compressor is ready for its regular work under the required condition of speed and pressure.

The unloader in no way controls the starting and stopping of the motor. It merely unloads the compressor and keeps it unloaded until it is again started and up to required speed. The control of the motor current is accomplished by some one of the standard controlling switches and circuit breakers.

The Yarnall-Waring Co., Chestnut Hill, Philadelphia, Pa., will in the future manufacture and sell all of the Richards air-controlling devices.

MACHINE-FIRING IN RAILWAY SYSTEM POWER STATION.

FORMBY power station is situated about half-way between Liverpool and Southport, England, close to the River Alt, thus ensuring a cheap and abundant supply of water for condensing purposes. Current is generated for the electric railway owned by the Lancashire & Yorkshire Railway Co. and links up Liverpool and Southport. The passenger traffic carried over this line in the course of a day is large, joining up as it does the important seaport shipping center with the residential seaside town of Southport. Trains follow each other in rapid succession from early morning until midnight in both directions and it will be understood that a delay on this section of the line would have serious results. It is thus very important that the principal factor in the power station, i.e., the steam-raising plant, should be maintained in a high state of efficiency and also be composed of units which after careful study have been found to be the most reliable under all conditions of working.

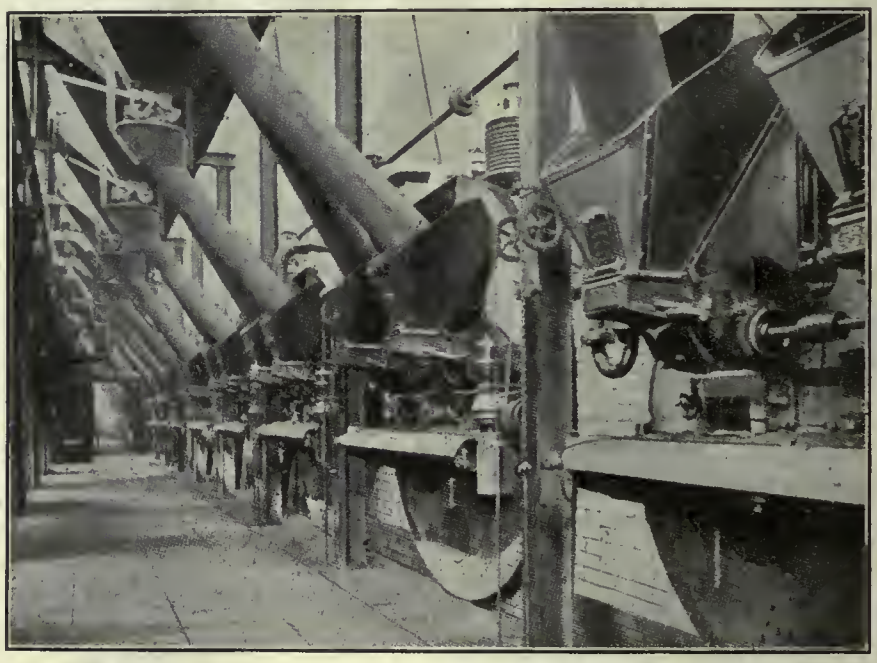
The Power Factor.

The power factor is necessarily an extremely variable quantity. At certain times of the day the trains are heavily laden and at other portions traffic is comparatively light. It is thus incumbent upon the officials to be certain that the steam-raising plant is highly flexible and that heavy peak loads may be easily taken when offered without imparing the efficiency of the line.

Coal is brought from colleries about twenty miles away, and is delivered by gravity from hopper wagons on to a bucket conveyor by which it is carried to overhead bunkers. From the bunkers, which hold about 130 tons, the coal is fed to the boilers by Bemis machine-stokers. The bucket conveyor, it may be mentioned, is also used for the disposal of the ashes. It should here be said that the boiler-room is 280 ft. long and 56 ft. wide and contains sixteen Lancashire type boilers. Each boiler is 32 ft. 6 in. long, 8 ft. 6 in. diameter, and has a grate area of 420 sq. ft., and 1,200 square feet of heating surface, with a normal evaporation of 12,000 lbs. per hour. The boilers are arranged in two batteries, north and south. The products of combustion on leaving each boiler pass through a superheater of 35 tubes, of 158 sq. ft. heating surface, and then go to the main flue, 10 ft. x 6 ft., which runs parallel to and against the wall between the engine-room and the boiler-room. The draught is induced by two fans 9 ft. 6 in. in diameter, one placed at each end of the main flue. Each fan has eight radial blades, being driven at a normal speed of 160 revolutions per minute by a compound vertical enclosed engine of 100 i.h.p. The products of combustion on their way to each fan pass through economizers, one being placed at each end of the flue. Each economizer consists of 720 tubes, 9 ft. long by 3 11-16 ins. internal diameter, embracing 7,200 square feet total heating surface.

Steam is generated at a pressure of 160 lbs. per square inch, and passed from each boiler through a superheater formed of a nest of U tubes, giving 150 deg. F. superheat into the main steam range. Each battery is a complete unit in itself, having, as already intimated, an efficient set of economizers so as to utilize the heat in the waste gases. A separate fan and chimney distinguishes each battery. At the same time, the arrangement of the dampers renders it easily possible to run the whole of the boilers through either set of economizers to either chimney. The chimneys are of steel, about 50 feet high, and the draught is created by a fan, direct-coupled to a high speed engine. It is possible when the fan is working at full speed to produce a suction equal to 2 ins. water gauge at the outlet of the economizers.

Previous to the installation of mechanical stokers, the boilers were hand-



BENNIS STOKERS IN A RAILROAD SYSTEM POWER STATION.

fired and burning a good class **Burgy** coal, but the constantly increasing demands for steam became a serious problem. After careful inquiry and due consideration, the railway company decided to install mechanical stokers, and Edward Bennis & Co., Ltd., who are represented in Canada by G. H. Tod, Toronto and Winnipeg, were given instructions to fit eight of these boilers, that is, the whole of the south battery, with their latest type **sprinkler** stokers and self-cleaning compressed air furnaces.

The order was placed subject to severe and minute guarantees. Any or all of these boilers were to be capable of evaporating 14,000 lbs. of water per hour as from and at 212 deg. F. for twenty-four hours continuously if required, and for peak purposes 16,000 lbs. of water per boiler per hour for short duration. Under special conditions as to feed temperature, pressure, superheat, etc., and when burning ordinary Lancashire **slack**, the boilers, whilst evaporating the quantities of water stated above were not to exceed a coal consumption of 1,200 lbs. for each 10,000 lbs. of water evaporated. The steam and power required for the driving of the stokers, fan, engine, steam jets, was to be deducted before the total evaporation was recognized. Without the fan at work and with very little draught available, each boiler was to evaporate 10,000 lbs. of water per hour.

The tests were carried out in the presence of the company's officials, and the results were highly satisfactory and more than fulfilled the guarantee given. The water was measured in tanks, each holding 10,000 lbs. of water, carefully weighed and calibrated, previous to the test. The coal was weighed in trucks on the company's weighbridge which was guaranteed correct to 7 lbs.

The tests showed that the over-all efficiency was 81 per cent on the whole eight boilers and on a maximum evaporation test the evaporation per boiler per hour, from and at 212 deg. F. reached 23,000 lbs. The economical guarantees were satisfactorily fulfilled and the plant was then taken over by the company. It should be stated that the fuel was changed by adopting the stokers to a much cheaper grade, and also that the boiler capacity had been increased. After five months' operation, instructions were given to fit up the remaining battery of eight boilers with similar stokers.

During the period that elapsed between the fitting of the two batteries, several improvements in the throwing mechanism of the stokers were introduced by the patentees, and, as a consequence, the last eight boilers were fitted with the **balanced double shovel arm gear.** The plant was erected and tested, to the satisfaction of the officials of the company and taken over, and the improvements in the throwing mechanism having given satisfaction, the latter has been since applied to the first eight stokers installed.

The boiler-house may now be considered as a scientific part of the whole generating plant. CO_2 recorders are installed, careful details kept of all particulars necessary to perfect combustion and efficiency, and test results have always been maintained, which fact is a credit alike to the stoker manufacturers and to those in charge of the plant operation.

BRONZE MIXTURES.

COMBATTING THE MENACE TO WORLD-WIDE FREEDOM.

CANADA IS AT WAR. Although hard of realization because of our distance from the territory in which the nations of Europe are so involved, 'tis nevertheless true. As a nation within an Empire to whom honor, freedom and right made duty clear, we are out to help wipe out the menace and crush the octopus of militarism which for years has kept Europe sitting on a powder barrel, so to speak; generally retarded the progress of civilization over all the world, and kept in chains and slavery a people who in spite of the latter have shown themselves to be worthy of a wider and higher field of effort.

We are at war now instead of later, because the time seemed opportune to his self-deified majesty, the Kaiser, and to those moral degenerates who pampered his inborn whim of a world dictatorship. We are not at war with the people of Germany, but on their behalf, for away deep down in their heart of hearts, could they now express it, there would be found hearty appreciation of the activities against the yoke of autocracy.

Whether the war be long or short, its termination will only materialize when freedom from the curse of militarism has been achieved, and the men and women of Germany have opportunity to turn their universally admitted talents to higher and nobler purposes. We are enthusiastic in Canada, because at one with the whole Empire in the determination to exterminate this military fanaticism once and for all, but we must needs be sober and be prepared to make the every sacrifice demanded.

In the mad rush amounting almost to panic that has been in evidence within our borders during the early days of this red letter month, we have had the spectacle of **Rule Brittania** being shouted at one moment, and in the next the attempt to corner everything in sight in the provision line, forgetting meanwhile that those who will make it possible for Britain and her allies to come out on top, will have in many cases to give of their life blood, and in others have to suffer and endure privation and hardship. Again, this food panic on the part of those who have the means is nothing short of criminal, playing, as it does, into the hands of human vultures who will not hesitate to screw prices up regardless of the sufferings of those who at normal times find it hard enough to make ends meet.

If we need not fight, it is because others are doing it for us, therefore let us at least acquit ourselves like men by sacrifice to keep our commerce and industries as close to normal as possible. It will be worth while, for of the ultimate outcome of the struggle there need be no fear because right is might. When the smoke of battle has passed, this old planet of ours will realize a prosperity hitherto undreamt of, much less attained, for the war spectre which aforetime stalked abroad stifling civilization and crushing humanity will have vanished in thin air. Needless to say, we in Canada will participate largely in that prosperity.

FOUNDRYMENS' CONVENTION AND EXHIBITION OPPORTUNITY.

THE opportunity to inspect and see in practical operation another year's achievement in foundry and accessory equipment is almost available and, together with the data relative to the ways and means of their accomplishment which will form the substance of the various papers to be read and discussed before and by the delegates in convention assembled, will make Chicago the Mecca of every foundryman for whom circumstances conspire favorably.

As in previous years, Canadian foundrymen, administrative and operative, will be much in evidence, but much as has been the representation in the past, we are of opinion that many more could not only be present, but for educative reasons should be so.

There is every indication that the coming convention and exhibition will, like its predecessors, be an easy record-breaker, and Canadian foundrymen of every class and kind should so lay their plans that theirs may be a record attendance, being assured that the educational reward will not fall short of bestowal on them.

INDUSTRIAL NOTABILITIES--No. 47

JAMES HENRY SHERRARD, president Alaska Feather & Down Co., manufacturers of beds and bedding, 400 Ambroise St., Montreal; vice-president, the Ideal Bedding Co., Toronto; vice-president, Alaska Bedding Co., Winnipeg; vice-president, The Alaska Western Bedding Co., Calgary; vice-president, Alaska B. C. Bedding Co., Vancouver, was born at Shediac, N.B., Sept 21, 1866, the son of Thomas F. and Mary Elizabeth (Durham) Sherrard.

He was educated at Shediac Grammar School, and started his business career with O. M. Melanson & Co., general merchants, Shediac, in 1883. He came to Montreal in 1891, and established the present business in the same year.

JAMES HENRY SHERARD.

Mr. Sherrard was chairman Montreal Branch Canadian Manufacturers' Association in 1911; is vice-president Canadian Manufacturers' Association for 1914; was alderman, Westmount, 1909; was chairman, Parks Committee; is vice-president, Victorian Order of Nurses, and a member Board of Management, Montreal General Hospital.

He married Lucy Warren Atwater, daughter of Henry W. Atwater, Montreal, June 24, 1898, and has one son.

His clubs are St. James and Canada, Montreal; Garrison, Quebec; National, Toronto, and Manitoba, Winnipeg; while his recreations are golf and fishing. He is a Conservative in politics and a Presbyterian in religion, and his home is 1 Forden Ave., Westmount, Que.—Photo courtesy the International Press.

The General Market Conditions and Tendencies

This section sets forth the views and observations of men qualified to judge the outlook and with whom we are in close touch through provincial correspondents.

Montreal, Que., Aug. 10, 1914.—The war in Europe has had the effect of putting an effective check on the very hopeful outlook of a few weeks ago. Since the declaration of hostilities there has been no real business transacted, but this, of course, is what would naturally be expected, because the situation is entirely unique, being one that knows no precedent. In a flash the whole of Europe has been precipitated into this struggle. Foreign exchange and all commerce has been suspended. The prevailing opinion here seems to be one of entire confidence in the ability of Britain and France to confine the hostilities within the boundaries of Germany, or at worst not far beyond these. The financial situation might be a great deal worse. Money is, of course, **tight**. However, no nervousness is evidenced, and up to the present no great difficulty in obtaining funds for business purposes has been felt.

The Steel Market.

During the past week very little steel has been purchased. Those firms who prefer to use European products usually carry fairly heavy stocks in hand, because of the fact that the delivery across the Atlantic takes several weeks under normal conditions. Thus, with little or no business their stocks remain complete. All orders are being filled, and no great change of price is to be noted. It is felt that it will only be a matter of a short time before trans-Atlantic shipping is resumed. No large orders are being sought. Some firms still have their salesmen on the road. Although the tendency is to conserve stocks of European steel, no orders are refused. All quotations are, of course, for immediate acceptance, and, therefore, are merely nominal. An important factor in assisting to steady the market is the fact that American rolling mills can supply the Canadian trade in the unlikely event of trans-Atlantic shipping being suspended very long.

Pig Iron.

The market in European pig iron remains quite steady. No delivery can be guaranteed. Several vessels which sailed before the declaration of war have since safely arrived, and no shortage is being felt meantime. The fluctuation in price is small. There is also here a tendency to conserve stocks; still no orders are being refused. Large orders are, however, scarce, because manufacturers are awaiting definite developments before purchasing.

Machine Tools.

Here, of course, the crisis is being felt more keenly than in any other line. No sales for the past week have been reported. Those firms representing European manufacturers, of course, cannot sell, because no delivery can be guaranteed. However, those houses dealing in machine tool supplies are enjoying quite a brisk business, and are able to keep their organization pretty well intact, although the turnover is quite small.

Metal Markets.

There has been no change in prices of metals except tin and aluminum. Tin has jumped up to 65 cents a pound, while antimony has gone up to 15 cents a pound.

Toronto, Ont., Aug. 11, 1914.—A week of suspense and uncertainty has passed, and the country is becoming rather more accustomed to a situation which is without a parallel in modern history. Having no precedents to follow as a guide in dealing with the situation, it will take some time for the business affairs of the country to become adjusted to the abnormal conditions. It is difficult, if not impossible, to foretell what effect the European war will have on Canada, but there is no doubt that it will disorganize trade for some time, the extent depending more or less upon the length of the struggle. Upon the ability of the Brit-

ish Navy to keep open the trade routes, of which we have no doubt, depends to a large extent the effect of the war upon trade, both export and import.

As far as can be seen at present it appears to be highly probable that the export trade will be increased, which will offset to some extent the depression in internal trade, which seems bound to result from the disturbance in financial circles, consequent upon the war. The export trade, however, only effects a few commodities, principally foodstuffs, and will not benefit our manufacturers to any appreciable extent.

It is possible that the entire surplus of this year's crops, not required for home consumption, will be shipped to the Old Country at a price which will result in a substantial return to the farmers, and offset the deficiency in yield which appears to be probable, judging from recent reports from the West.

Steel Market.

At this writing, the iron and steel markets are in rather a chaotic condition owing to the uncertainty as to what effect the war will have on the trade of the country, and also on account of the financial disturbance following on the outbreak of hostilities. There is every possibility of a drastic curtailment in building operations and municipal works, although we believe the latter will be carried on as far as is possible under the circumstances. We understand that the Dominion Government will continue progress with public works as far as the financial situation will allow.

Tin plate and galvanized sheets have advanced in price, but the market is so irregular that it is practically impossible to obtain quotations except against definite specifications and for prompt acceptance. The European sources of supply have been temporarily cut off, leaving only firms in the United States to supply the market. The prices of steel products have advanced, which, together with the increased difficulty of making satisfactory financial arrangements, will no doubt hinder the development of both private and public works. Makers of agricultural implements who do a large European business, will suffer severely, and will no doubt be obliged to curtail their operations.

In some lines no contracts for future delivery are being booked, quotations being made only for immediate acceptance. Prices are sure to fluctuate, and little business is being done. The British Government has prohibited the export of all metals, including ferro-manganese, which will vitally effect steel manufacturers, and what export trade we have in steel products will be stopped for the time being until the trade routes are reopened.

The United States Steel Corporation has withdrawn all prices on its products, and quotations have been advanced $2 per ton. The reason we believe is partly on account of the favorable rate decision by the Interstate Commerce Commission, and also because foreign competition on certain products has been eliminated. This advance will, of course, affect Canada, but how long it will remain in force or be still further increased remains to be seen. It is highly probable that the United States mills will eventually benefit from the war through their export trade.

Pig Iron.

Pig iron is perhaps the least affected of any. Owing to the conditions which have prevailed for some time in the market, comparatively little pig iron has been imported from the Old Country; the cutting off of the supply from that source will, therefore, not have much effect. The price of pig in the United States remains stationary, consequently prices have not changed except in the case of "Victoria" iron, which is slightly weaker. There is little business being done, and the market is very quiet.

WAR MARKETS.

NOTE.—Owing to the unsettled condition of the markets generally, and consequent upon rapid fluctuation in prices, it is impossible to give firm prices in our selected market quotations for many products, as prices on a number of lines are liable to change daily or oftener. The quotations will, however, serve as a guide while at the same time indicating the general trend of the market.

Machine Tools.

Little can be said regarding the machine tool market, except that there is practically no business being done, and prospects for an improvement are hardly possible until the European crisis is on a fair way to a settlement. A certain amount of business in single tools will no doubt be done right along, but orders of any size are not likely to be placed. The business which was expected from the railroads will be delaped indefinitely.

Metals

The metal markets as regards the amount of business being done are distinctly quiet; one firm, however, report satisfactory business. The war has cut off the supply of tin, which has jumped to 70 cents. The tin situation is assuming serious proportions, and a famine is probable. The British Government has prohibited the export of spelter and antimony, the supply of the former having also been cut off from Germany, consequently a further advance may be expected. Antimony advanced to 25 cents and spelter to 6 cents a pound to-day. Copper is steady, but an advance may be expected; prices are quite nominal. Both London and New York Metal Exchanges are closed indefinitely.

Ottawa, Ont., Aug. 10, 1914.—With the first scare over the war news passed, business is settling down to a little more like normal. That Canada was on the verge of a financial panic a week ago when the war scare was at its height is undoubted. In a number of Ottawa banks there were incipient signs of a run. Sir Edmund Walker and other banking leaders at once came to Ottawa, and a conference was held with Hon. W. T. White. As a result of the prompt action taken by the Government, the danger of a panic was stopped. Financial men at the capital believe that now even if things started to go against the allies there would be no serious disturbance in Canada.

How will the war affect Canada is the question that is now being asked in official financial circles? It is the belief that as soon as Great Britain secures absolute control of the sea and commerce to the United Kingdom can pass without danger of menace, trade will immediately pick up, and that there will be a big improvement in business conditions. That Western Canadian farmers and agriculturists will receive higher prices is undoubted. The millions of Europe cannot be taken from the farms of that continent without having a serious effect on the grain markets of the world. Higher wheat prices will help out the West, which, to speak frankly, has only about a sixty per cent. crop, and high prices will tend to compensate a little at least. While many manufacturing lines will be seriously hurt by the war, and will have to run on half-time, yet industries which produce commodities needed in warfare will be given an impetus. Leather manufacturers, cotton manufacturers, etc., will without doubt see an improvement in conditions.

Many Government officials in the Trade and Commerce Department believe that the result of the present war should give an impetus to Canadian export trade in manufactures. They point out that Germany now is an enormous exporter to South Africa, South America and Australia. They think that as soon as the trade lanes are free, Canada should be able to secure more than its share of the present German trade in these countries.

The announcement that the Canadian

Government had offered the Imperial authorities a million bags of flour and that the offer has been accepted has more than a sentimental side to it. It has an important business side. Owing to the difficulties in the exchange market, due to the financial moratorium in England, it has been impossible to send any foodstuffs to the Old Country. The port of Montreal is crowded with grain and other foodstuffs, which the shippers are willing to take chances on moving if they could only make the necessary financial arrangements. The Canadian Government, along with the English authorities, are making arrangements for the shipping of this grain, flour, etc. This will tend to relieve the situation, while it will generally assist the business situation in Canada.

It is the general belief that the industries which will temporarily be hurt most will be those relating to iron, steel and machinery. Railroad construction is bound to drop off, if not to stop altogether. The C. N. R. only got part of its bonds sold before war broke out, while the Grand Trunk Pacific bonds have not been put on the market, and cannot be now. Both roads will certainly have to curtail work.

Winnipeg, Man., Aug. 8, 1914.—The Grand Trunk Pacific Railway, who recently asked prices on a long list of machine tools for their McBride shops, have since notified dealers that the order for these will probably not be placed for some time. This action is said to be the result of the war in Europe. Most firms are cutting down their demands, and improvement is not anticipated until things are more settled.

The Saskatchewan Bridge & Iron Works of Moose Jaw have secured a contract for several bridges, the steel for which is coming forward to be fabricated at Moose Jaw. Their new plant at Medicine Hat is making progress towards completion, and when the work is finished, machinery will be installed gradually.

The Canadian Fairbanks-Morse Co., commenting on the business being done, state that woodworking tools have been up to the average this year, although inquiries are dropping off now. Metalworking tools they have found much duller this year than last. Jobbers are taking no chances on carrying stock under present conditions; yet, while admitting that machine tools are moving slowly, they state that a fair business is being done in supplies.

Wells & Gray, Ltd., Toronto, have been awarded a contract for the erection of a factory at Windsor, Ont., for the Remington Arms Co.

FORBIDDEN CANADIAN EXPORTS.

A proclamation was issued by the Government at Ottawa, on August 7, prohibiting the exportation from Canada of the following articles:—"Aluminum, aluminum alloys, armor plating, armor quality castings and similar protective materials, asbestos, cables, telegraph and telephone, camp equipment, articles of cannon and other ordnances and parts thereof, carbolic acid, carriages and mountings for cannon and other ordnance and for machine guns and parts there of, coal, steam and large compasses and parts thereof, including fittings, such as binacles cresol, engine and boiler packings, explosives of all kinds, fuel, manufactured implements and apparatus designed exclusively for the manufacture of munitions of war, for the manufacture or repair of arms, or of war material for use on land and sea; india rubber sheet, vulcanized, manganese, mercury, mica, mineral jellies, mines and parts thereof, molybdenum nitrocresol, nitrates of ammonium, nitrates of potassium, nitrates of sodium, nitratulol, nitric acid, picric acid and its components, range-finders and parts thereof, rope and steel wire, and hawsers, saltpetre, sounding machines and gear, steam vessels, lighters and barges of all descriptions, sulphur, sulphuric acid, swords, bayonets and other arms not being firearms and parts thereof, tin, tinplates, torpedo tubes, torpedoes and parts thereof, tungsten, vanadium, four-wheeled wagons, capable of carrying one ton and over, two-wheeled carts capable of carrying 15 cwt. and over, harness and saddlery of all kinds, brass wire for long spans 450 lbs., per mile, horse and pony shoes, materials for telegraphs, wireless telegraphs and telephones, field glasses and telephones, field glasses and telescopes, railway materials, both fixed and rolling stock, men's marching and shooting boots, heliographs, portable forges, farriers', carpenters', wheelers' and saddlers' tools and transport service sets, glycerine, alcohol as covering rectified spirits uniform clothing and military equipment, accoutrements, walnut wood of scantling which can be made into rifle butts and forends."

WEST INDIAN TRADE.

THE results of the preference given to Canadian goods by the West Indies under the recent treaty made therewith were reviewed in a report to the Trade and Commerce Department recently by Commissioner Tripp, of Trinidad. In a number of cases, the preference has been without result, among them the following:—Cement, glass, glassware and plated ware, boots and shoes, brooms and brushes, butter, meal, hardware, lard, iron and steel manufactures, milk, paper, etc. It is to be concluded that there was an object in placing cement in the tariff bill, as the exports of that commodity from Canada have greatly diminished during the last few years. It is presumed that the local demand exceeds the supply, says the report.

There are several commodities, however, which, it is considered, should be open to Canada to supply in the near future, such as china and earthenware, coal and coke, electrical apparatus, jewelery, and refined sugar. Then there are a number of commodities which have already shown the beneficial results of the trade agreement and which have been received in increased quantity from Canada since the treaty came into effect. These include traveling bags, cordage and twine, cars, carriages, etc., flour (this being a striking increase), farinaceous preparations, meats in brine, paints and manufactures of wood.

May Acquire Nail Co.—It is stated in circles close to the Dominion Steel Corporation that considerable progress has been made in negotiations leading up to the acquisition of the Maritime Nail Co. by the Dominion Steel Corporation. Under present plans, should the deal go through, it is the intention to merge the Maritime Nail business with that of the nail department of the Steel Corporation, and take over the staff of the Maritime Nail Co. to operate the nail department of the Steel Corporation.

C. G. E. Patriotic Offer—The Canadian General Electric Co., Toronto, gave tangible expression in the accompanying telegram to Premier Borden of their desire to be of service to the Empire and the Dominion in the present crisis, and, needless to say, acceptance was gratefully acknowledged:

"Toronto, August 6th, 1914.

"The Right Honorable
Sir Robert L. Borden,
Prime Minister, Ottawa, Ont.

"The Board of Directors of the Canadian General Electric Co., after full consideration, and having regard to the present serious war situation, have resolved to submit to your Government an offer to raise, equip, and pay the salaries of a company of twenty-five skilled electrical and mechanical operatives who would be available for service in any part of the Dominion, and be under the control of the Minister of Militia as part of the Canadian forces. Probably their services could best be uitlized in the erection, repair and maintenance of wireless telegraph stations, cable stations, bridges, transport vehicles, artillery, etc.

"(Sgd.) Frederic Nicholls,
"President."

Engineering

Redcliff, Alta.—The Imperial Brass Mfg. Co., of Chicago, Ill., will build a factory here.

Jonquieres, Que.—A New York syndicate is contemplating erecting pulp and paper mills here and a power plant at Alma. B. A. Scott, of Quebec City, is interested in the project.

Sault Ste. Marie, Ont.—The new open hearth furnace at the Algoma Steel Corporation steel plant is now making steel and the first heat was tapped with satisfactory results on August 3.

Humboldt, Sask.—The town council has awarded to Theodore Kipp & Co., of Winnipeg, the contract for the supply and installation of pumping machinery and accessories for pump house at $12,350.

Princeton, B.C.—The British Columbia Copper Co., will make extensions to their plant at Copper Mountain. Machinery for the treatment of ore will be installed, and a large pump will be required.

Galt, Ont.—The officers of the Galt Machine Screw Co., Ltd., are R. W. Roelofson, president; F. D. Palmer, vice-president, and C. K. Jansen, secretary-treasurer, all of this town: The company is capitalized at $40,000.

Galt, Ont.—Ratepayers last Monday voted on two by-laws—one for a loan of $12,000 to the Galt Machine Screw Co., and the other for $20,000, to be expended on roads and machinery. The vote was small, but both passed by more than 250 majority.

Halifax, N.S.—President Harris, of the Nova Scotia Steel & Coal Co., has announced that as a result of the unprecedented financial situation created by the war it has been decided to close down a portion of the plant at Wabana Mines, and the blast and open hearth furnaces at Sydney mines have been temporarily stopped.

Ford, Ont.—It is reported that a $300,000 addition to the Ford Motor Co.'s plant will be erected at once. The new section will replace the only remaining old buildings. The new building will be six storeys high and 200 feet square. It will be of reinforced concrete, of the same design as the main building of the plant.

Hedley, B.C.—The Granby Consolidated Mining, Smelting & Power Co. now has three blast furnaces running at its copper smelting works at Anyox, the third furnace having been blown in lately. The capacity of the plant is stated to be about 2,000 tons of ore a day, but tonnage figures have not been made public as yet, so it is not generally known what quantity of ore is actually smelted daily. Besides its Hidden Creek mines, near Anyox, the company is operating two mines in south-east Alaska; and the ore from these is also to be shipped to the works at Anyox for reduction .

AUSTRALIAN RAILWAY WORKSHOP TENDERS.

Tender forms for the undermentioned supplies required for the Victorian Government Railway shop at Ballarat and Bendigo have been received by the Canadian Government Department of Trade and Commerce, Ottawa. Tenders close at Melbourne on September 23, and the last mail available to Canadian manufacturers is that leaving San Francisco on September 1.

27085—44 tons copper rod.
27086—109 tons copper plates.
27087—19 tons best iron angles.
27088—347 tons steel boiler plates
27089—4,244 cwts. brass locomotive tubes.
27090—476 cwts. copper locomotive tubes.

Electrical

Florence, Ont.—The proposed route of the hydro-electric road from Strathroy to Dresden will pass through this town.

Nottawa, Ont.—The question of extending hydro-electric lines here is being considered.

The Dominion Machinery Co. have received an order from the Cordova Mines, Ltd., for two 75 and one 10 h.p. Westinghouse motors, transformers and other electrical equipment.

Brantford, Ont.—Work on the Hydro-electric branch line between Brant sub-station and Port Dover is to be completed immediately, and in a short time Hydro power will be available for Burford, Scotland and elsewhere. Engineers have been over the ground and laid out the route, and construction of the line will be gone ahead with as rapidly as possible.

Municipal

Berlin, Ont.—It is announced that there will be no civic abattoir established here.

Belleville, Ont.—The by-law endorsing an agreement with the Trenton Electric and Water Co. has been passed by the ratepayers.

Cranbrook, B.C. — Work on the new city water works will start next week. The contractors are Leder, Hotson & Goode, of Lethbridge, Alta.

Moose Jaw, Sask.—The Southern Saskatchewan Oil & Gas Co., which has its head office in the Walter Scott building, have appealed for the franchise to supply natural gas to the city.

Saskatoon, Sask. — The ratepayers have defeated the by-law conferring a 20-year contract to supply and distribute gas in this city. Voting was 608 for, 600 against. As a two-thirds majority is required, the by-law is beaten.

Haileybury, Ont. — Continuing their agitation for cheaper light the town council on August 3, discussed the by-laws of the Hydro-Electric Commission. The Northern Ontario Light & Power Company's franchise expires early next year.

Ottawa, Ont.—Hazen & Whipple, of New York, are the engineers in charge of the preparation of plans for the Ottawa River water supply. It is stated that these will be ready for submitting to the Provincial Board of Health for approval by the middle of August. The plans are for the construction of a filtration plant.

St. Thomas, Ont.—Reeve Smith, representing the township of Yarmouth, and a special committee of the board of works, held a meeting recently, relative to the proposed Hughes street viaduct. The estimated cost of the improvement is placed at $7,582. Filling in will cost, $2,000; culvert, $1,600; excavation, $1,978; pipe, $1,904.

INDUSTRIAL EXPANSION NUMBER

August 20th 1914

Vol. XII CANADIAN MACHINERY AND MANUFACTURING NEWS No. 8

Facts and Figures Relative to Industrial Opportunity

Staff Article

The accompanying article seeks to focus within easily appreciable compass the widespread natural resources, developed and otherwise, and the desirableness of a multitude of locational opportunities from the viewpoint of raw and finished market product transportation by land and water, which the Dominion of Canada offers manufacturers, enabling thereby prompt and wise decisions to be made concerning the establishment or extension of particular enterprises.

CONSIDERABLE progress has been made during the last twelve months in the industrial development of Canada, although the expansion in trade has been retarded by a severe depression, now somewhat aggravated. The position of most industries is sound and the check only of a temporary character, to be followed in due course by a period of good trade which will surpass any which the country has yet experienced.

An encouraging feature is the boundless faith which manufacturers in this and other countries have in the future of Canada. This is especially true of manufacturers in the United States, who are coming over in greater numbers every year and building branch establishments to take care of their increasing business with us. More manufacturers from Great Britain are establishing branches here now than formerly, having realized the opportunities which this country offers. The difficulty of obtaining reliable information regarding suitable locations is becoming less every year, as many organizations are at work with the object of furnishing information to help prospective industries.

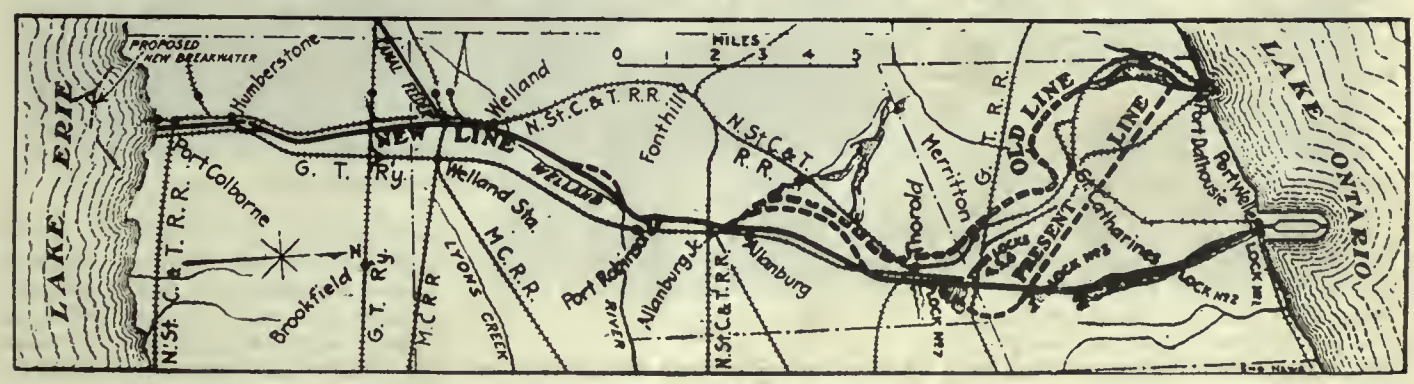
Manufacturers desiring to locate in Canada are confronted with problems varying according to the features of their particular industry, and the authorities in our industrial centers are becoming more alive to this situation, with the result that in the majority of cases they have taken definite steps to meet any necessary requirements. In all cases there is a Board of Trade, while some cities employ an Industrial Commissioner, often at considerable expense, whose duty consists of preparing and distributing literature containing facts and figures regarding the city and other general information, covering population, assessment, tax rates, railroad and shipping facilities, accessibility to markets, cost of power, etc. These authorities, in all cases, give every possible assistance to prospective manufacturers.

The inducements offered vary considerably. Some cities, by nature of their location, enjoy certain advantages that others are not favored with, and so can offer inducements which do not involve much financial outlay. Cheap power is a primary consideration, and when combined with good transportation facilities at low rates, makes a very attractive proposition. Some industries, again, require that raw materials shall be within easy reach, while to others this is not such an important consideration. It will, therefore, be seen that each city has its own problems to solve when offering inducements to prospective manufacturers. Each case has to be treated on its merits, according to what the city has to offer, and also the size and nature of the industry.

As a general rule, a fixed low assessment for a term of years and a partial remission of taxes can be obtained, while in some cases free sites are available. Some cities operate their own power plants, and in others attractive rates can generally be obtained from private power companies. The questionable system of giving a bonus is rarely practiced now, although a guarantee of bonds is often made. Transportation facilities are improving each year. In many industrial districts there are two or more railways and some have a further advantage of water transportation.

Water Power.

Canada is well supplied with water power, which in many cases is within



THE NEW WELLAND SHIP CANAL, SHOWING ITS RELATION TO THE PRESENT AND OLD CANALS.

reach of manufacturing districts. This is a valuable asset, and one that will be of the greatest assistance in developing the natural resources of the Dominion. In Nova Scotia about 16,000 h.p. is being developed; in New Brunswick, 10,000 h.p.; in the province of Quebec, 300,000 h.p.; Ontario, 560,000 h.p.; Manitoba, 60,000 h.p.; Alberta, 8,000 h.p.; and in British Columbia approximately 110,000 h.p. It has been estimated that over 17 millions h.p. is available in Canada.

SHAWINIGAN FALLS, NEAR THREE RIVERS, QUE.

By far the most important water power is that of Niagara Falls, Ont., where 405,000 h.p. is being developed on the Canadian side out of a possible 425,000 h.p., this being the maximum allowed under treaty with the United States. The largest power company on the Canadian side is the Ontario Power Co., who supply a large part of their current to the Ontario Hydro-Electric Commission for distribution. The Commission is a Provincial Government proposition, and the transmission lines serve a large part of Ontario. The lines are being extended each year until practically the entire province will eventually be connected up with hydro-service. The Commission are developing other water powers in the province, making thereby a complete system. It will thus be seen that the industrial expansion of Ontario is assured each year, showing it to be attracting more industries.

In the province of Quebec, the possibilities of hydro-electric development are great, but in many cases the water powers are as yet undeveloped. The principal water powers being developed are at Shawinigan Falls, Lachine, S. Timothee, Chambly, and Cedars Rapids. The city of Montreal obtains power from all of these sources for operating the public utilities.

The next most important province with regard to water powers is British Columbia, but development has not reached an advanced stage. The city of Vancouver has 200,000 h.p. available, but is only using about half that amount at present. Only a small percentage of the water powers in this province have as yet been gauged.

In Manitoba, it is estimated that 400,000 h.p. is available. At present, however, only about 60,000 h.p. is being developed, principally at Lac du Bonnet, which supplies the city of Winnipeg with power.

In the other provinces, the development does not call for any special mention, although in the majority of cases the large powers are waiting development as the demand calls for it.

Coal.

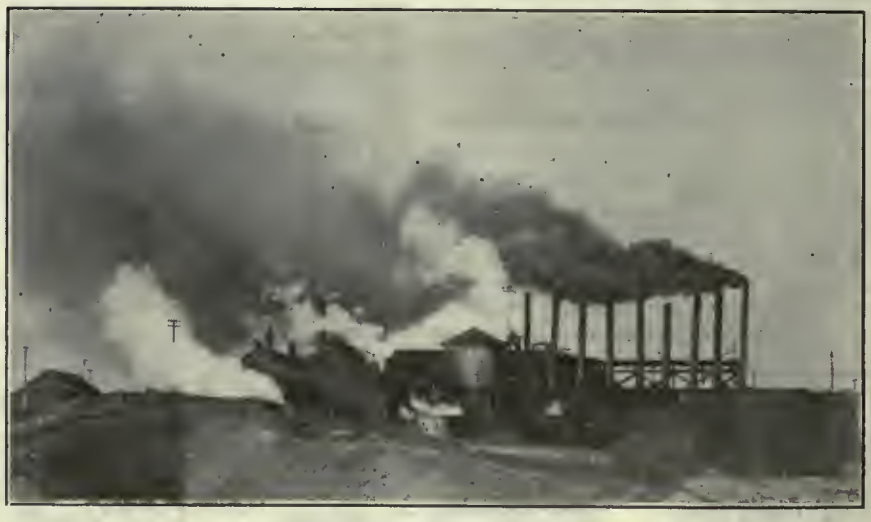
A considerable amount of the coal used in Canada is imported from the United States, the reason being on account of the location of the coal fields. There are practically only four districts where coal can be obtained, these being at Sydney, N. S., in Alberta, in the southern part of British Columbia, and on Vancouver Island. The output from the Sidney district is the largest, amounting to about seven million tons of bituminous coal in 1913. The output from the mines in Alberta was about four million tons, including bituminous, anthracite and lignite. In British Columbia about three million tons of bituminous coal was produced, including the output from the mines on Vancouver Island. In Saskatchewan an effort is being made to develop the lignite coal areas. It will be seen from the above why so much coal has to be imported from the United States.

Natural Gas.

In some directions natural gas is being used for industrial and domestic purposes. In Alberta, New Brunswick, and Ontario, natural gas is being used extensively, and further developments are anticipated. Petroleum is often met with in gas fields, but the development of this product has not attained the same measure of success as natural gas. Oil is, however, being found in fair quantities in some districts, and better results are expected.

The Market Feature.

We have referred briefly to the power feature obtaining in Canada, and will now deal with the question from a geographical standpoint. A country extending over 3,000 miles from coast to coast naturally offers a great variety of conditions to be considered by the prospective manufacturer. The position becomes complicated when considering the question of accessibility to markets for the product. The greatest industrial developments in the United States have



GALT COAL MINE, LETHBRIDGE, ALTA.

been in the Northern States, east of Chicago, and a similar condition may be said to exist in Canada. The result has been that up to the present time the greatest development has been east of Fort William. One reason for this is the greater population, and therefore better markets, and another the proximity to

GREAT WEST LUMBER CO. PLANT AND LOG POND, RED DEER, ALTA.

that section of the United States where the larger number of industries are located. Although the Eastern Provinces still continue to attract the greater proportion of new factories, a decided change in the situation is taking place, and the Western Provinces are making great progress in the development of new industries.

Each year sees new plants starting up in Winnipeg, Medicine Hat, Calgary, Edmonton, and other prominent cities, these all becoming manufacturing centers and distributing points for extensive territories.

Ontario has made greater industrial progress than any other province on account of its location and proximity to the United States. Many manufacturers from over the line prefer to have their branch establishments as near the home plant as possible, and for this reason have located at such points as Windsor, Walkerville, Welland, Thorold, St. Catherines, Hamilton, Toronto, Montreal, etc.

In the West, Winnipeg, Calgary, Vancouver and other cities have the same advantages on account of their proximity to Chicago and other manufacturing centers in the Western States. The reason as stated is, of course, distinct from other advantages offered by the various cities, and also so far as the development of Canada by British capital is concerned. Other considerations have naturally entered into the situation, one of these being the cheap power which is obtainable in greater or less degree in practically all manufacturing cities. Transportation facilities are unusually good with two or more railway systems, and in some cases supplemented by water transportation.

In the Maritime Provinces, industrial development has not been as marked as in some of the other provinces, although Sydney, C.B., and Halifax, N.S., and St. John, N.B., are important cities, especially the former, where is located the Dominion Steel Corporation plant. In the province of Quebec, lumbering and pulp and paper mills are very important industries, while Montreal, Sherbrooke, and Three Rivers are the principal manufacturing centers.

The industrial development is well distributed throughout the province of Ontario, except for the northern section, which is mostly confined to the mining industry only. The principal manufacturing centers are Toronto, Hamilton, and the Windsor district; the Niagara peninsula, including Welland, Thorold and St. Catherines; London, Berlin, Galt, Guelph, etc. In Manitoba, Winnipeg is the principal manufacturing and distributing center, while in Alberta, Edmonton, Calgary, and Medicine Hat are developing into important industrial cities.

Comparatively little development has so far been made in Saskatchewan along manufacturing lines, except in the cities of Saskatoon, Regina, and Moose Jaw, where a number of industries are established and good progress is now being made. In British Columbia, including Vancouver Island, Victoria and Vancouver are important cities commercially and are making great progress as manufacturing centers. Lumbering, mining, and fishing are important industries, and a number of factories, mills, and canneries are being established to take care of the increasing demand for the various products.

British Columbia.

The principal cities in British Columbia are Victoria, the capital, on Vancouver Island, and Vancouver on the mainland. Both cities owe their import-

SHIPPING LUMBER FROM HALIFAX, N.S.

ance to their natural location and fine deep-water harbors. Steamers trade

from these ports to the Far East and Australia, and great developments are expected with the opening of the Panama Canal. The Dominion Government is spending large sums of money in improving the harbors at both ports, while a large drydock will be located at Esquimault. The population of Victoria in 1913 was 50,000 and the assessment $116,000,000.

Vancouver at the same period had a population of 122,000, with an assessment of $227,000,000, although these figures do not include the adjoining municipalities of North and South Vancouver, which have populations of 12,000 and 40,000 respectively.

Prince Rupert, the Pacific terminus of the G.T.P., was incorporated about four years ago, and has a population of about 7,000. The first train arrived in Prince Rupert on April 9, 1914, making a red-letter day in the annals of that city. A fine harbor is being developed, and already a 20,000 floating dry-dock is being constructed, which when completed will be stationed there. The industrial possibilities of Prince Rupert are great, as there are a number of water powers awaiting development, after which cheap power will be available. Fishing, lumbering, and canning industries will eventually be established, while the development of the mining industry will be an important factor in the upbuilding of the city. Several towns, such as New Westminster, Kamloops, Fernie, and Nelson are centers of districts where fishing, lumbering, mining, and fruit farming are being developed.

INDUSTRIAL AND MANUFACTURING BUILDING, PRINCE RUPERT, B.C.

$2,000,000 PLANT UNDER CONSTRUCTION FOR THE GRAND TRUNK PACIFIC DRYDOCK AND SHIP REPAIR CO., PRINCE RUPERT, B.C.

Alberta.

The province of Alberta is better known as a cattle ranching and farming country; coal, however, is being mined in considerable quantities, and, in addition to being a source of wealth, will help considerably in the development of manufacturing. Calgary, Medicine Hat, and Edmonton are the most important industrial centers, while smaller towns such as Lethbridge, Red Deer, and Red-cliff are attracting quite a number of factories. Natural gas, which is found in large quantities, principally in Bow Island and the Medicine Hat district, is an important factor in the growth of the above cities, cheap gas being available to manufacturers. On the Bow River, near Calgary, 10,000 h.p. has been de-

CALGARY, ALTA., FROM THE NORTH HILL.

ALBERTA CLAY PRODUCTS CO. PLANT, MEDICINE HAT, ALTA.

veloped, providing a further supply of cheap power in addition to natural gas. In the northern parts of Alberta there are large water powers awaiting development, approximately 800,000 h.p. having been gauged up to date. As already stated, a considerable amount of coal is mined in this province, the coal fields covering an extensive territory to the north and west of Calgary, the city being the chief market. Edmonton, the capital, has a population of 70,000, Calgary 80,000, and Medicine Hat 14,000.

Saskatchewan.

The province of Saskatchewan is essentially a grain growing country, but considerable development is in progress in certain cities, notably Saskatoon, Regina, and Moose Jaw, while Battleford, Yorkton, Prince Albert and Swift Current are also becoming important distributing and industrial centers. There are few water powers of any importance in this province, La Colle Falls, near Prince Albert, being the only one of any size that is being developed. There is no coal, with the exception of lignite, but exhaustive tests are being made in an endeavor to find the best method of burning it, in the form of briquettes or otherwise. Saskatoon has a population of 30,000, with assessment of $54,000,000. The population of Regina is 50,000, with assessment of $73.000,000. Moose Jaw has a population of 30,000, with an assessment of $52,000,000.

Manitoba.

Manitoba and Saskatchewan are the wheat-growing provinces of the Dominion, and both derive the greater part of their wealth from this source. Manufacturing has made little headway, except in Winnipeg, which is fast becoming the Chicago of Canada. The population of Winnipeg is about 225,000, and the assessment approximately $260,000,000, a remarkable growth considering that it is only forty years since the incorporation of what was then a small town. Winnipeg is an important distributing centre, and has in addition an ample supply of cheap power. Approximately 60,000 h.p. is being developed at Lac Du Bonnet, while large powers on Winnipeg River are awaiting development. There has been practically no coal discovered in Manitoba, and consequently a considerable amount has to be imported from the United States.

Ontario.

Industrial development in Ontario has been greater than in any other province, and the reasons are many. Ontario is one of the older provinces, and has the largest population. Its very close proximity to the United States is one reason why many manufacturers from that country have established factories within its borders. Transportation facilities are good, power is cheap, coal is not far away, and a good supply of labor is available. Toronto and Hamilton are the most important manufacturing centres, while there are a number of smaller cities which are showing considerable development. Among the latter might be mentioned Ottawa, Berlin, Brantford, Chatham, Fort William, Galt, Guelph, Ingersoll, London, Peterborough, St. Catharines, St. Thomas, Sarnia, Welland, Sault Ste. Marie, Stratford, Thorold, Walkerville, Windsor, Whitby, etc.

The population of Toronto is about 445,000, and the assessment this year is approximately $516,500,000. The bank clearings in 1913 were about $2,000,000,000, and building permits for the same year totaled $27,000,000. Hamilton has a population of 100,000, its building permits for 1913 amounted to $5,000,000, and its assessment $76,000,000. The population of Ottawa is 89,000, and that of London, 50,000.

There is hardly a known industry which is not represented in Ontario, while in the northern section of the province some of the largest silver mines in

DOMINION GLASS CO. PLANT, REDCLIFF, ALTA.

OGILVIE FLOUR MILLS, MEDICINE HAT, ALTA.

SASKATCHEWAN BRIDGE AND IRONWORKS, MOOSE JAW, SASK.

the world are being developed. Cheap power is available in all the above mentioned centres, principally through the agency of the Hydro-Electric Commission, whose transmission lines will ultimately serve the entire province. In the Niagara Peninsula, the Cataract Power Co. and the Hamilton Power and Transmission Co. also have lines extending throughout the district. In Western Ontario, natural gas is being used extensively for both industrial and domestic purposes. Tilbury being one of the more important places where gas is found. No coal of any commercial value is mined in this province, consequently practically all the coal used is imported from the United States. Although gas is found in large quantities, comparatively little oil has been found of any commercial value. As already stated, the largest water power development is at Niagara Falls; there are, however, numerous minor water powers either being developed or awaiting development as the necessity arises. Other natural resources include lumber, iron, nickel, silver, and various miscellaneous metals, while farming and fruit-growing are important industries.

STREET SCENE, REGINA, SASK.

Quebec.

Quebec is one of the oldest provinces, and in point of population comes second to Ontario. The industrial development of Quebec is widely scattered on account of the lumbering industry, which is perhaps the most important in the province. It is estimated that the forest area is about 130,000,000 acres. A considerable variety of mineral deposits are being developed, asbestos being the most important, with a production of about 112,000 tons last year. No coal is mined in the province, the greater part used coming from Sidney, N.S., while the remainder, chiefly anthracite, is imported from the United States. Immense water powers exist in this province, aggregating over 1½ million h.p. already gauged. Only a comparatively small amount has as yet been developed, the principal developments being Shawinigan Falls, Lachine, Chambly, and Cedars Rapids, the latter being the largest, although not yet in operation.

The principal city is Montreal, the largest city and foremost port in the Dominion. Montreal is also a long way in front of any other city in the province as a manufacturing centre, being very favorably situated for attracting industries. Montreal is at the head of ocean navigation, has cheap power from several hydro-electric plants in the vicinity, both rail and water transportation facilities, and ideal labor conditions. The population of Montreal proper is 568,000, and of Greater Montreal 652,000. The assessment is approximately $791,000,000. The building permits for 1913 were valued at $27,000,000 . Sherbrooke, Hull, Shawinigan Falls, and its neighbor Three Rivers, are important manufacturing centres where cheap hydro-electric power is available. A number of smaller towns, although they have comparatively small populations, support some industries. Quebec City, although of considerable importance as a seaport, has not as many industries as might be expected, considering its location and cheap power at hand. Quebec City has a population of about 85,000, Sherbrooke 20,000, and Hull 21,000.

New Brunswick.

The Province of New Brunswick, together with Nova Scotia and Prince Edward Island, form what are called the Maritime Provinces. In New Brunswick the principal industries are lumbering and fishing, including canneries. The forest areas are large, the Provincial Government owning over 10,000 square miles. The total value of the fisheries in 1912 was nearly $5,000,000. A number of mineral areas are being developed, but not very extensively. Coal is being mined at Grand Lake, and iron ore near Bathurst. Shale deposits, from which oil is obtained, are being worked in Albert and King's Counties, while natural gas is being obtained in commercial quantities near Moncton. There are a number of water powers from which about 10,000 h.p. is obtained.

Fredericton, the capital, with a population of 9,000, has a number of important industries. St. John, however, is the principal industrial centre, and in

ONTARIO PAPER CO. PLANT, THOROLD, ONT.

addition is an important seaport, being the winter terminal of a number of the trans-Atlantic liners. In recent years, St. John has made considerable progress as a manufacturing centre, and is also an important distributing centre for the Maritime Provinces. Extensive harbor improvements are now in progress, and the Dominion Government is spending a large amount of money in this development. The population is about 45,000. Moncton has a population of 15,000, and is perhaps best known as being the headquarters of the Intercolonial Railway.

CITY HALL AND PRINCIPAL STREETS, THREE RIVERS, QUE.

Nova Scotia.

Nova Scotia, with which we will include the Island of Cape Breton, has an extensive seaboard, and consequently fishing is an important industry, being the largest in the Dominion. It is estimated that over six million dollars are invested in the fishing industry, which provides employment for over 40,000 people. Lumbering is also an important industry, about 200,000,000 feet being exported yearly. The estimated forest area is 780 square miles. The minerals being developed are coal and iron, the Cape Breton and Glace Bay districts being the most important.

The Dominion Coal Co., alone at Glace Bay, have, it is estimated, sufficient coal in their holdings to provide for an output of 3½ million tons per year for 1,000 years. The output for each year is nearly 7,000,000 tons of bituminous coal. Iron ore is found in several districts, but on account of the Newfoundland deposit being nearer to Cape Breton, the large steel companies at Sidney import iron from there, consequently the iron mines in the province have not been developed to the extent that they would otherwise have been. There are a number of water powers in Nova Scotia, but although comparatively small, are exceedingly valuable on account of their advantageous position.

Halifax, the capital city, has a population of 55,000, and an assessment of about $31,000,000. There are a number of important industries in Halifax, including a large sugar refinery. Halifax has a fine harbor, and improvements are in progress, costing several millions of dollars. Halifax is a winter port of call for most of the trans-Atlantic liners. Sidney has a population of 22,000, and is famous as being the headquarters of the Dominion Steel Corporation, the largest of its kind in the Dominion. At Glace Bay, twenty-one miles distant, is the centre of the Dominion Coal Co.'s properties. New Glasgow is the headquarters of the Nova Scotia Steel and Coal Co. and the Eastern Car Co.

Newfoundland

Newfoundland, the oldest British colony, has not been developed very extensively. Lumbering, fishing, iron mining, pulp and paper manufacture are the principal industries. There are a number of water powers, a small proportion only being under development. The capital city, St. John's, has a population of about 34,000, and is both the largest city and the most important distributing centre. Wabana Island contains larger deposits of iron ore than any other district in the Dominion.

Soot Fall Data—Careful measurements were made during the past year by means of which it was determined that the soot fall in Pittsburgh ranges from 595 to 1,950 tons per square mile per year. London, England, has been considered one of the "gloomiest" cities in the world, yet the soot fall there is only 426 tons per square mile per year.

PICKLED FISH EXPORT, HALIFAX, N.S.

The Progressive Maritime Province of New Brunswick

By J. B. Dever

A fund of not only interesting but highly useful information concerning this Eastern section of our Dominion is available from a careful study of the following article, and as the details have been secured first-hand by the writer from observation and residence in the territory, prospective settlers, manufacturing or otherwise, cannot fail to profit.

THE Maritime Provinces of Canada offer splendid opportunity for industrial expansion and development. The success attained by many large manufacturing houses in past years presents substantial evidence of the fact, and each succeeding twelve months adds its share of generous support to the statement. Last year, when from all parts of Canada, the United States and large European centres came pitiable bewailing regarding the financial situation and the business outlook, there was a clearly apparent air of contentment in the East because, though progress was checked to a slight extent, there was no actual stay in advancement, much less a set-back. This was true of all cities and towns through the Atlantic Provinces, but particularly so as regards St. John, N.B.

Industrial Activities.

St. John has a Board of Trade. Furthermore, it is an active organization, and possessing a very energetic and capable secretary and industrial commissioner in the person of R. E. Armstrong. Is he appreciated? Well, it is hardly proper to ask the question in this form, but it might be said in all truthfulness that his efforts are appreciated. His endeavors to further the industrial development of the city have been quite successful, and the board has supported him ably.

St. John offers much to attract outside industries to locate, and the city is ever ready to grant all consistent concessions to a deserving manufacturer. There is no definite form of concession. No bonus is given by the city, but an inducement is offered in the way of special favors as to exemption from taxation for a certain period, reduction in taxation for a fixed term, provision of a site by the city and other privileges, the only consideration demanded being the employment of a certain number of workmen and the definite establishment of the industry within limited time mutually agreed upon.

This policy has proven quite satisfactory. It is not only applied to outside concerns, but industries starting from within the city have been favored under it. In ten years, up to 1911, the capital invested in manufacturing industries in St. John increased 80 per cent.; but since that time the tremendous development of its transportation facilities has attracted many new factories, and there are at present works of enormous magnitude under way. There has to a certain extent been a slight movement, hardly amounting to a migration, of industrial plants from the city to the suburbs; for instance, in the case of the T. S. Simms Brush & Broom Co., who have built a new structure of reinforced concrete in Fairville, just outside the city limits. The Maritime Assembling & Service Co. have a large plant within a short distance of the city at Coldbrook, where also the Ford Motor Co. have their works. In these cases it is not correct to speak of the establishments as being migratory, but more properly as part of a movement for the founding of large manufacturing enterprises just on the outskirts of a city.

The Housing Problem.

With the discussion of this phase of industry, the establishment of factories in the suburbs, comes the consideration of the housing problem. This is now being grappled with in St. John. Before long it is hoped to have neatly arranged rows of workmen's cottages on land owned by the city or private concerns on the outskirts and connected with the heart of the town by street railway service. The rails from the city streets are now being extended outward, and are approaching Coldbrook, where it is planned to have a **Garden City,** and where the suburban industrial movement so far as St. John is concerned will likely be selected. A few miles further out the Canada Cement Co. have acquired a huge limestone and clay deposit, and will construct a large modern plant, showing again the movement towards the suburbs in the sphere of industry. The Wilson Box Co. have enlarged their plant and added more modern machinery. They also are located in a suburb, as is the case with another new industry, the Moore Woodenware Factory. In each case efforts are being made to have the workmen employed properly housed in the immediate vicinity, and extensive plans to this end are now well advanced with a view to holding skilled labor in the suburban districts in question.

Transportation Facilities Constructed and Projected.

The importance of adequate railway and water facilities to the development of industries is one of the most important factors in the consideration of a location. Without these little can be done. One of the first questions an intending manufacturer will ask, after ascertaining the value and extent of the raw products to be developed, is as to the shipping facilities. Large sums of money have been expended about St. John to develop and equip the port. Millions more are now being put out to make it still more fitted to the rapidly growing trade, and thoroughly deserving of the title of "Canada's Winterport." In dredging and dock construction to provide accommodation on the eastern side of the harbor for the Grand Trunk and Canadian Northern Railways, each of which it has been announced will make St. John its winter terminus, fully $30,000,000 are being expended. The huge breakwater being built by the Norton-Griffiths Co. is rapidly nearing completion, and a start will soon be made on the stretch of two miles of docks where twenty-three modern, large-sized steamers can find accommodation. Seventy acres of land have been purchased adjacent to the docks by the Grand Trunk Railway for terminal facilities, elevators, shops and other appurtenances. On this side of the harbor also is to be constructed by the Norton-Griffiths Co. a gigantic dry dock and ship repair plant. In a few years will be found here a new harbor rivaling some of the best on the Atlantic coast, and superior to many.

Winter Port of St. John.

On the western side of the harbor is to be found the winter terminal of the Canadian Pacific Railway. The third big elevator at this port has this year been completed by this corporation, and they have announced that at least $1,000,000 yearly will be spent by them in keeping their facilities adequate to cope with the traffic demands. The city and the Dominion Government are co-operating with the C.P.R. in this matter, and contracts totaling more than $10,000,000 have been provided for by the Government in dock construction, dredging, and in the extension of the present breakwater to a much greater distance. New wharves and berths are now being built by the Maritime Dredging & Construction Co. In the main harbor also, the Intercolonial Railway is developing its facilities, and soon must provide greater equipment for the increasing trade. It should be noted that all this harbor work being done provides for the docking of

the greatest steamships afloat. In addition to the other roads mentioned, the St. John Valley Railway will make its terminal at this port, and when completed will have opened up a vast area of valuable and as yet almost unknown lands with their unlimited supply of natural products to the manufacturer.

Throughout the Province of New Brunswick as a whole new railway lines are penetrating and bringing to the seats of manufacture the best to be had from the inner regions in raw material and natural resources to be moulded into marketable commodities by the wheels of industry.

Industrial Expansion and Possibilities.

During the last few years, St. John's industrial houses have passed through a period of expansion and growth which has been most encouraging. New plants have been established, and old ones have been made more modern and enlarged, and there is a strong feeling that in the near future there will be established in St. John a steel shipbuilding plant. The Norton-Griffiths Co. have acquired 100 acres west of the dock to be built for the purpose and, close by, other interests have taken upon themselves the acquisition of land as a site for a smelting works and steel plant. The work on the plant of the Atlantic Sugar Refineries will soon be completed. It is now nearing the final stages, and refining will begin some time this fall.

At a cost of $1,000,000, T. McAvity & Sons, Ltd., will extend their already large plant to a new site in the Marsh Road, where a most up-to-date brass and finishing foundry will be erected. Six times within the last eight years the Maritime Nail Works have extended their plant, employing 300 hands, and still further expansion is planned. Other industries are especially active, particularly those more recently established, including the Canada Brush Factory, Simms Brush & Broom Co., Oil Motor Co., Ltd., Ganong Confectionery Co., and the Royal Vacuum Cleaner Factory. Of course, the older plants have been kept busy as well.

As to the possibilities of industrial expansion about St. John, with so much raw material available and the transportation facilities up to the standard, the opportunities for manufacture are almost unlimited. There is believed to be room in St. John for a brick manufacturing plant, a furniture making factory, a structural steel concern, a paper factory, and other manufacturing branches. As to the first named, tests have been made, and it is learned that there is an abundance of workable clay near at hand. There are only two such plants here now. Negotiations in one or other of these lines have been carried on relative to having such plants locate in St. John, and a decision is pending in regard to some of them.

The Power Question.

For some years, various schemes have been discussed for harnessing the great water powers along the St. John River and turning it into service. There is practically a monopoly of electric power held now by the St. John Railway Co., but different schemes are being given consideration whereby other power plants may supply also. These schemes have by no means been abandoned, though one or more may appear dormant at present. One of the most fondly cherished hopes of St. John manufacturers is the possibility of having natural gas from the wells near Moncton piped to the city. These wells have proved of rare value to manufacturing plants in and near Moncton, and their importance for domestic supply is also fully realized. Late borings have improved the situation considerably. There is a good supply of bituminous coal in Queen's County, not many miles from St. John, which can be had cheaply for steam purposes at about $2.25 a ton.

General Trend Towards Advancement.

Throughout New Brunswick generally there is every indication of progress. Each town and city throughout the province is experiencing a period of activity, and building permits have been issued to a greater amount than for many years. Moncton is attracting especial attention through its proximity to the oil and gas wells, and its possibilities as an industrial and railway centre. There are many big commercial enterprises under way in Campbellton, where in one month recently fifteen permits for building were issued. Newcastle, Woodstock, Fredericton, Sackville and St. Stephen are all joining in the forward movement, and in the last named place there is a prospect of the establishment of a harbor of national importance to be brought about by improving the natural environment. A large new shoe factory has recently been built there also.

At St. Andrews, progress is being made on the new hotel to be erected to replace the Algonquin, burned some weeks ago. It will cost about $250,000. Speaking of hotels, it may be said that plans are under way for the erection of two large hostelries in St. John—the Hotel Carleton and the Hotel Imperial six and eight-storey structures. From Fairville to St. John the new spandril arch bridge of steel being erected by the Provincial Government is being rapidly stretched across the Reversing Falls, and, when this has been completed, the C.P.R. intend building another steel cantilever bridge alongside.

All of the foregoing facts tend to show the prosperity of the East. There the people have confidence in the future and look for further progress. Manufacturers are shipping their goods to the Pacific Coast in one direction and the West Indies in another, and the name of New Brunswick's industrial houses is more and more becoming better known and recognized for its worth. There is reason to believe that the next few years will see even a more marked development, and that the era of industrial expansion, of which mention has been made, will continue to at least keep pace with other sections of the Dominion.

The Work and Worth of Municipal Boards of Trade

By A. G. W.

It seems only natural to infer from its very constitution that a Board of Trade where established would be a prime factor not only in the effort to secure industries but also in placing them. As an institution considerable development has quite recently taken place, with the result that even in comparatively small towns such a body is organized.

THE industrial progress of Canada as exemplified in our various manufacturing centres is largely due to the formation of Boards of Trade in the majority of our cities and towns. It is reasonable to suppose that a body of citizens working together for one cause can accomplish more than any individual effort, however, well directed, and a Board of Trade can accomplish still more in this direction than even the local civic council. It is organized for a particular purpose—to foster trade and confine its energies to that particular end. Furthermore, the members of Boards of Trade are usually representative citizens anxious to see their city grow and its councils are selected from the more prominent members.

Organization of a Board of Trade.

Boards of Trade or chambers of commerce may be formed as corporations independent of the Government under the provisions of an Act passed in 1886. Either may be formed by thirty persons connected with representative industries or professions, and who are resident in

the district. The various vocations include merchants, traders, brokers, mechanics, manufacturers, bank managers or insurance agents. A certificate of formation under hands and seals of the original or charter members must, however, be filed with the Secretary of State. It will thus be seen that a Board of Trade, although not a Government appointed body, occupies a position of much importance, and its rulings and decisions carry considerable weight in the community.

The officers are president, vice-president and a council of not less than eight members who appoint a secretary. General quarterly meetings must be held each year but usually meetings are held more frequently than this, according to the amount of business to be transacted or when called for special purposes. Persons other than the above mentioned can only become members upon recommendation of the council. The corporation have power to elect twelve persons who shall form a board of arbitration and any three members shall have power to arbitrate on cases submitted to them. The Canadian boards of trade are not official organizations to the full extent that obtains in Great Britain, but they probably are more effective in one way—that of encouraging new industries. This has become in recent years, perhaps the chief reason for their formation in many cases.

Duties of a Board of Trade.

While it is true that they are in a position to influence legislation and often exercise that privilege, yet in the majority of cases their chief work lays in the direction of furthering the commercial interests of the municipality on business lines rather than legislative. The only exception to this, in what may be called principle rather than rule, are the boards of trade in some of the larger cities such as Montreal and Toronto. In both these instances the boards do not make any particular effort to encourage new industries but rather confine their energies to general work in connection with manufacturing and commercial undertakings, assisting those interested in every possible way, either by promoting legislation or generally endeavoring to further their development.

Occasionally their work assumes national importance, such as the stand taken by the Montreal Board of Trade over the Long Sault power development controversy which readers of Canadian Machinery will remember and appreciate. This case briefly, was an attempt by a powerful United States corporation to develop a large water power at the Long Sault Rapids on the St. Lawrence River, for the benefit of manufacturers across the border at the expense of Canada. The influence of the Montreal Board of Trade with other organizations opposed to this scheme, went a long way towards defeating it. This incident serves to show how a strong organization, such as this board is, can be of the greatest service to the country generally, as well as to the municipality in which it is located.

As already stated, the boards of trade are organized with a view to improving the industrial conditions in the municipalities where they are formed. The best proof of the success of these organizations can be seen in the fact, that nearly every town and city in the Dominion has a Board of Trade. They are becoming practically indispensible and are doing much valuable work. In a new country like Canada where syndicates, companies and private individuals are continually looking around for suitable locations for factories, it is absolutely essential that, if a town desires new industries, it should be in a position to negotiate with the prospective manufacturer and have the necessary organization to deal with the situation. It must have a representative body with full powers to negotiate and lay before the prospective manufacturer all the inducements which they are prepared to offer and, in addition, have complete data as to sites, freight rates, cost of power, etc. Unless this information be given promptly there is little hope of landing any new industries. This service a board of trade is able to render if conducted on proper lines.

Industrial Commissioner Feature.

An important official is the secretary or in some cases the industrial commissioner. He should be the scout of the organization and also the chief of the **Intelligence Department.** An active secretary or commissioner will go a long way towards making success of a campaign to attract new industries. We have a case in mind where a large concern had practically decided to locate, but the industrial commissioner of an adjoining city heard of this and immediately went to interview the principals of the company, and stayed with them until he had induced them to locate in his community. The city that lost this industry had no organization to deal with a case of this kind, and the incident serves to show how essential it is that a municipality should have an active organization to take care of such conditions.

In most cases the secretary is in the receipt of a salary, the amount usually depending upon the duties attached to the position. An industrial commissioner as a rule devotes his whole time to the work and is paid accordingly, often with an attractive salary. It can hardly be expected that a small city would be able to pay for the services of a commissioner, but the larger cities find it a profitable investment. The point is that if an active campaign is to be instituted, there must be a qualified official to conduct it and he naturally must be paid accordingly. The location of the city and inducements which can be offered are of course a vital consideration in deciding as to advisability of incurring such expenses.

Civic Publicity.

In the more progressive towns, the board of trade conducts a systematic advertising campaign, involving the printing and distribution of literature, setting forth the various inducements which the town can offer, and such other particulars as are likely to interest prospective manufacturers. The advisability of such a campaign naturally depends upon what the town has to offer, but generally speaking, success has attended the majority of such campaigns. The literature is distributed to parts where it is likely to be most effective, a considerable amount usually finding its way to the United States, from which country a large number of manufacturers are coming each year to establish Canadian branches. Both eastern and western cities will continue to attract new industries as long as they can deliver the goods.

This publicity committee, or industrial commission feature of the board of trade, is one that has developed within the last few years and is a new departure in civic work. It has now come to be a recognized factor in the growth and expansion of municipalities throughout the country, from coast to coast. Practically every town, except the very small ones, has a board of trade and a large proportion of these organizations have a publicity or industrial committee. A board of trade would be neglecting one of its most important duties if it failed to appreciate the value of civic publicity, the foundation of which must be a committee of energetic members backed up by the board and a suitable appropriation for the work.

There is no question but that the board of trade idea is a good one, and one that has been responsible to a great extent for the development of many of our manufacturing centres. The idea is good both in theory and practice, for the members comprise men who are most likely to have the best interests of their town at heart, and their position in the community entitles their views on industrial questions to be respected. It is to be hoped that these organizations will continue to still more further the interests of their respective communities as they have in the past, and assist as far as possible all industries, established and prospective by every legitimate means in their power.

Specific Industrial Opportunities for Manufacturers

By a Staff Reporter

No individual, however generally superior in the eyes of his fellows, has a monopoly of gifts or is a perfection in personality, and we esteem it well that it is so. In like manner no one location in our Dominion has a monopoly in the matter of attracting industries. With the almost endless variety of the latter there is fortunately an equivalent personal condition existent; manufacturers have therefore a wide choice and can shrewdly estimate the value to themselves of the different facilities offered.

INDUSTRIAL DEVELOPMENT AT TORONTO, ONT.

THE phenomenal growth of Toronto, as a manufacturing center, up to the present time, has been of a haphazard nature and absolutely without aid from the civic or other public bodies who in other cities spend so much time and effort to secure new industries. The opening of the year 1914, however, witnessed the commencement of a work which marks a new era in Toronto's industrial history, and with which the people of the whole North American continent are by this time thoroughly familiar; to wit. the gigantic plans of the Toronto Harbor Commissioners for the development of the city's harbor and waterfront. The section of this development regarded by the commissioners as its most important work is the reclamation of the Ashbridge's Bay district for the purpose of providing an ideal location for industries of every description. From now on industries seeking a location in Canada will be taken in hand by the Harbor Commissioners of Toronto, and will be shown factory sites in an industrial district within a mile of the heart of a big city and served by railway sidings connecting with all three Canadian Transcontinental Railroads in addition to service at public docks by lines of freight vessels carrying cargoes from Montreal in the East to the head of navigation at Fort William in the West.

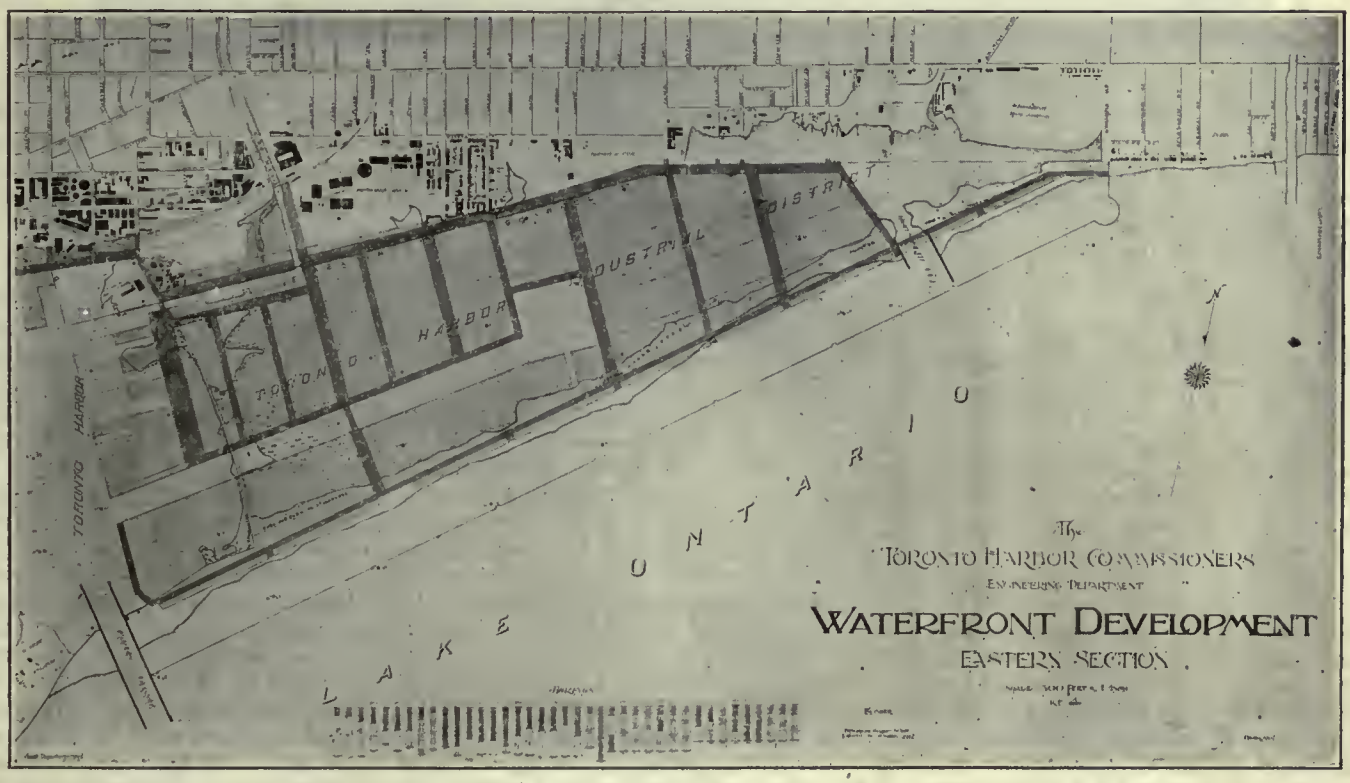
Transportation Facilities.

The Harbor Commissioners have provided for an expenditure of $15,000,000 to place this industrial district in condition for use and when their work is completed they will have created 646 acres of land available for industries on which it is estimated 1,000 new factories can be located. These factory sites have been laid out on the lines of most modern developments, railroad siding reservations totaling thirty miles in length having been set aside by the commissioners for the purpose of serving the district and each individual lot. These sidings will be at the service of factories locating on the property of the commissioners and will be free of expense to them. Thirty miles of streets varying in width from a minimum of 75 feet to a maximum of 175 feet will be provided for pedestrian, vehicular and street railway use and five miles of docks will be constructed to serve the shipping needs of the district.

In planning for railroad service in the Toronto harbor industrial district under which name Ashbridge's Bay will be known in future, the commissioners have made a traffic agreement with the three railroads under which there will be no interswitching charges, the result being that factories locating on the lands of the commissioners will receive or ship goods over any one of the three lines without being subject to the vexatious charge of from $5 to $8 per car which is inflicted on factories located on only one line of railway. This feature will be appreciated by manufacturers who have the service of only one railway at the present time.

Reclamation Work.

The reclamation work as outlined above is already well under way, substantial progress having been made during the present summer on contracts which amount in total to over eleven mil-



THE INDUSTRIAL DEVELOPMENT OF TORONTO, ONT.

lion dollars. Over 100 acres of land has already been reclaimed, one large modern dock served by 24 feet of water has just been completed and work is rapidly progressing on the first section of a ship channel 400 feet wide by 7,800 feet long, which will provide access for large vessels right into the heart of the district. The dredging and pile-driving plants of three companies in addition to the fine modern plant owned by the commissioners themselves have been busy at work since June carrying out the plans prepared by the commissioners and approved by the city council and Dominion Government and, by the end of the present season, the citizens of Toronto will see very substantial progress on an undertaking for which they have waited many years. With the completion of this reclaiming work, Toronto will be placed in a position to compete for factories with other Canadian cities and will be able to offer intending locators, modern factory and shipping facilities in addition to the advantages which are naturally hers.

TORONTO'S NEW UNION STATION AS IT WILL APPEAR WHEN COMPLETED.

THREE RIVERS, QUE.

ABOUT the beginning of 1914, the Board of Trade of Three Rivers thought it advisable in the interest of their city to try and induce English, American and Canadian industries to locate there. They felt that the Dominion of Canada as well as the United States and foreign countries were not aware of the advantages they had to offer, and with a view to bringing these before the world, they inaugurated a new department, known as the department of Publicity and Industry. They engaged as commissioner, W. J. Shea, who has had considerable experience in this field, to look after the work. Already the wisdom of the move is being felt in the city proper, as on all sides, enthusiasm among the citizens is noticed, and civic pride is taking the place of mere personal issues. The department is at present negotiating with several prominent capitalists who contemplate locating in Three Rivers.

In addition to its advantages as a manufacturing centre, they have been attracted by the inducements which the city offers in the way of free sites, tax exemptions and a freedom from labor troubles, more or less prevalent in the larger centres. Cheap and adequate help is always available and has done much in bringing the name of Three Rivers before the outside world.

There are at present several very important industries located there, the most important being the Wayagamack Pulp & Paper Co., who specialize in **Kraft** paper, and employ over 600 hands with an annual pay roll of over $500,000. This company represents an investment of $3,000,000. The next in importance is the Wabasso Cotton Co., which began operations a few years ago with capitalization of $1,250,000. They have lately doubled the size of their plant and are employing now over 1,000 hands.

The lumber industry has always been the backbone of Three Rivers and the surrounding country, the lumber supply coming from the forests extending more than 300 miles up the St. Maurice river. It is estimated that over 500,000,000 feet of timber come down the St. Maurice annually, which is converted into lumber, pulpwood and paper. The population is over 19,000 inhabitants, which represents an increase of almost 100 per cent. in the last fifteen years.

Outside manufacturers are gradually becoming aware of the fact that a city such as Three Rivers, built on the very shore of the St. Lawrence, the highway to the Atlantic seaboard with a harbor of two miles in length and with a depth of 52 feet, make it possible to accommodate the largest vessels afloat, is bound to command recognition sooner or later. The cheap power feature which Three Rivers is now offering, due to the arrangement with the Shawinigan Water & Power Co., situated a few miles from there, is one of the most important factors in its development as an industrial centre.

The community are uniting their efforts to make of this city a bigger, greater and better Three Rivers and have adopted the slogan **Watch Three Rivers Grow.** They feel that their city is destined to become the Buffalo of Canada, for the reason that the great power available at Niagara had much to do with Buffalo's making, and they naturally conclude that Shawinigan power, which is second only to Niagara, is bound in time to make the importance of Three Rivers felt throughout the world.

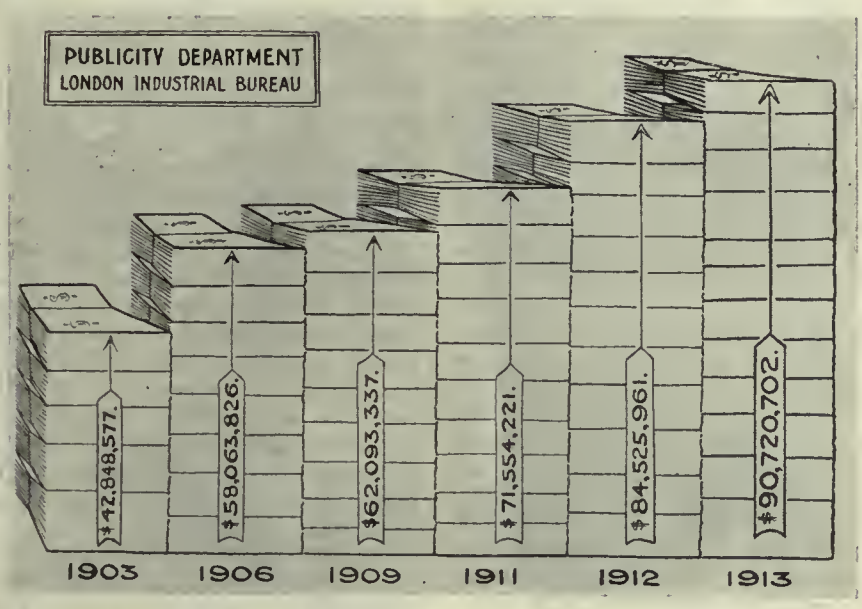
GUELPH, ONT.

FORTY-EIGHT miles west of Toronto lies the City of Guelph on the main line of the Grand Trunk Railway, and on the Toronto, Hamilton and Goderich branches of the Canadian Pacific Railway. The Toronto Surburban Electric Railway owned and operated by the C. N. R. also runs into Guelph, thus making very favorable transportation facilities and correspondingly cheap rates.

Guelph owns and operates all the public utilities including the Guelph Radial Ry., the waterworks, gas works and the Guelph Junction Railway, with a matter of 15½ miles of track leased to the C. P. R. It has an unlimited supply of hydro-electric power which is distributed at low rates, while gas can be obtained at 80 cents per 1,000 cub. feet for

manufacturing purposes. Other inducements offered to new industries are free sites and loans at a low rate of interest.

Guelph is the centre of a fine farming country, and the home of the Ontario Provincial Winter Fair, which is held annually and attracts thousands of visitors. The Ontario Agricultural College and Experimental Farm are also located at Guelph, and form a valuable adjunct to the farming industry of the Province. Among the more recent industries to be established are those of the International Malleable Co., and the Guelph Stove Works.



COMPARATIVE BANK CLEARINGS, LONDON, ONT.

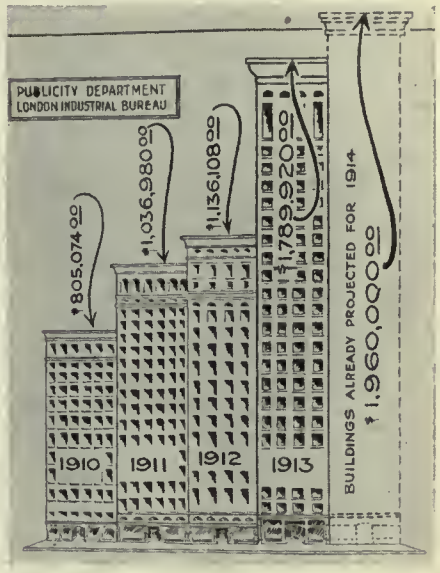
LONDON, ONT.

DURING the past three years—years not particularly favorable to development — London has made greater advancement than is recorded in its remarkably steady growth since incorporation as a city over eighty years ago. The figures of building permits, bank clearings, population and other statistics of civic progress, show greater percentages of annual increase in 1911, 1912 and 1913, than any previous year.

There is a tide in the affairs of cities, as well as of men, which if taken at its flood leads to increased prosperity and prestige, and Londoners, wise in their generation, early this year showed their faith in the city's future by authorizing expenditures which will mark an epoch in the city's history. This is the rehabilitation, electrification and municipal operation of the city-owned road to London's harbor, on Lake Erie, Port Stanley. At a cost of $700,000, this 23-mile line—a valuable heritage secured by the city fathers over sixty years ago—with right of way from the water front to factory, uncontrolled by the railways, will give London shippers the advantage of a competitive water route, owned and controlled by the city.

The London and Port Stanley Railway.

This unique municipal enterprise will be managed by a civic railway commission, which has already been appointed, and has done some good work already in getting the ties and steel on the ground since authority for the work was granted by Act of Parliament only a few weeks ago. The electrified line—now leased to the Pere Marquette and operated by steam has accessibility to the heart of the city with interswitching to all railways. London has four trunk and seven branch lines, and forms the

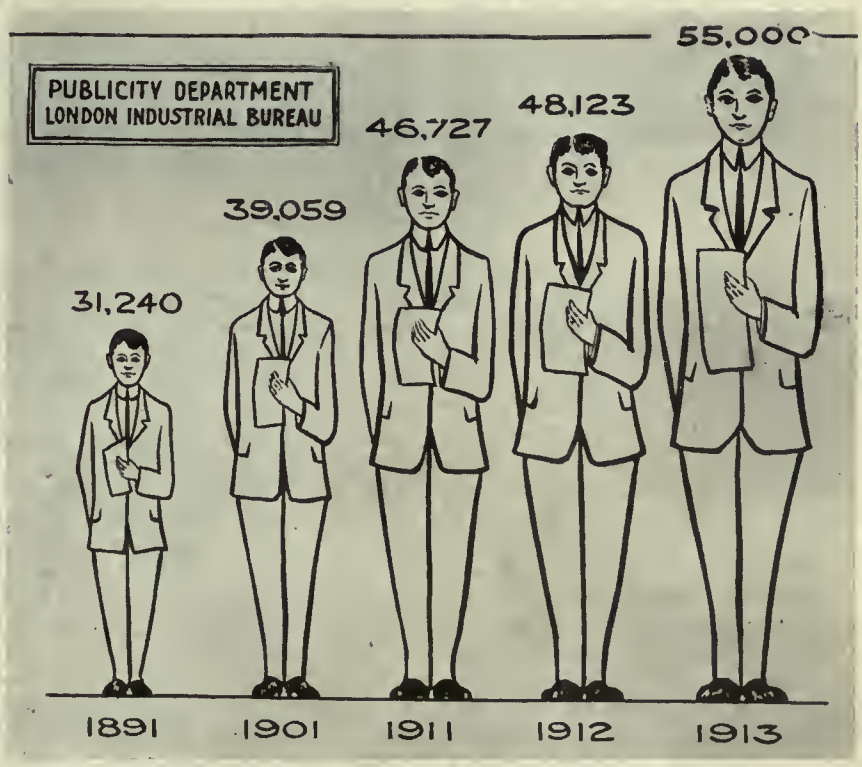


COMPARATIVE BUILDING PERMITS, LONDON, ONT.

key to the hydro-radial situation of the Western Ontario Peninsula, being the natural center of the network of radial lines for which surveys are now being made. Some of these are to Aylmer, Stratford, Sarnia and other points, passing through the rich agricultural districts en route.

Miscellaneous Statistics.

The figures of London's growth, population and building permits and



COMPARATIVE GROWTH OF POPULATION, LONDON, ONT.

bank clearing increases are shown in the diagrams accompanying this article. Manufacturing output as shown by the Government census 1910, has increased from between $8,000,000 and $9,000,000 to $18,600,000; or 100 per cent. in the ten years, 1900 to 1910. This figure, however, does not indicate the industrial increase which is taking place at the present time. Some idea of this is to be got, however, by comparison between the Government census figures, 1910, and figures first compiled by the London Industrial Bureau. These show that in the matter of employees engaged in the various spheres of industry, there has been a remarkable increase since 1910. Here are some increases: — Boot and shoe manufacture, 189; bread, biscuits and confectionery, 716; cement, brick, tile, etc., 22; flour and grist mill products, 58; iron, steel, foundry and machine shop products, 109; furniture and upholstered goods, 89; hats, caps and furs, 63; jewelry and repairs, 35; liquors, malt, 35; lumber products, 325; printing, publishing and bookbinding, 125; tobacco, cigars, etc., 435. Under the classification of **all other industries** in the Government list are various lines for which the number of employees is not given separately. To these have been added 31 enterprises employing between 500 and 600 people. London's factories numbering over 250, now employ between 12,000 and 13,000 people.

Manufacturing Advantages.

To manufacturers, London holds out general inducements unequalled anywhere in Canada. There are four trunk lines of railway and seven branch lines centering in and radiating from it, and with a city-owned harbor at Port Stanley and a city-controlled railway to that harbor, with interswitching on all railways, London has a competitive water route to every place, that other cities not on the line of ocean steamships, possess.

There is no place in Canada, it is claimed, where convenient factory sites can be obtained so cheaply according to the density of settlement as in London. There is plenty of ideal acreage right in the city with railway trackage and interswitching privileges, at from $500 an acre upwards. There is even some free acreage on the outskirts of the city. In any case it costs only hundreds to locate here where it costs thousands in many other cities. There are other reasons. London affords cheap power, cheap water, cheap fuel, abundant and high quality labor and low fixed assessment—single tax to manufacturers.

It seems to be a natural industrial center, where labor may be procured, where raw material may be assembled, and where cheap fuel is abundantly available. An economic manufacturing and distributing center for articles used throughout the whole Dominion. It has a call on the wealthy Eastern market and the rapidly growing Western market with, in addition, a home market of upwards of a million people, being in the very heart of prosperous, bustling Western Ontario.

Though London is 23 miles from Lake Erie she can boast of harbor advantages over cities with their own waterfronts. Owning the Port Stanley harbor, controlling the London & Port Stanley Railway, and with interswitching privileges to the siding of all railways, fuel and raw material can be brought to all London factories with one handling. London has easy access to Buffalo, Conneaut, Cleveland and other United States ports, and all Canadian ports. Coal comes in and is placed on the sidings right at the plants at $2.60 to $2.80 per ton.

As a special inducement to manufacturers the city has adopted an unusually liberal policy of granting a fixed assessment of 15 mills for fifteen years on lands values only, with exemption from taxation on buildings and plants. This covers a factory area of approximately 1,800 acres recently added to the city to the east and south, including Ealing, Pottersburg, Knollwood Park and Chelsea Green.

General.

At present power in London is five per cent. lower than Toronto, and electricity is 15 per cent. lower. A further reduction of 25 per cent. is promised for next year. The city gives especially low water rates to manufacturers, and the water supply of London is so pure that the Grand Trunk Railway dining car department use it without filtration. The average of freight rates to all parts of the Dominion is lower from London than any other eastern city of comparative size.

Natural gas is not yet into London, but it is piped to the city limits, and the Southern Ontario Gas Co. is preparing to submit a proposition to the ratepayers to supply natural gas to manufacturers at an economical figure. The local gas company at present supplies manufactured gas for industrial purposes.

London is famed for its labor supply, skilled and unskilled, male and female, and serious labor troubles are practically unknown. Prices of land are not yet high enough to prevent the head of a family owning his own home, and it is estimated that 80 per cent. of the heads of families own their own houses, which speaks well for living conditions in the city. It is the center of a rich agricultural section and produce is brought directly from farm to consumer at the city market three times a week.

Workingmen's houses cost from $1,800 to $2,000, and rent at from $12 to $16 a month.

BERLIN, ONT.

BERLIN or **Busy Berlin** as it is often called, is a city that has made considerable progress as a manufacturing center. The industries are varied, the principal being furniture, rubber, leather, shoes, shirts, etc. On account of the diversified industries employment is afforded for both males and females, making thereby labor conditions particularly favorable. In addition, the city is well supplied with parks making it desirable from a residential point of view. The population is over 18,000, and assessment about $9,000,000.

Berlin believes in municipal ownership, and owns all the public utilities including the waterworks system, gas and electric lighting plants and street railway. It was one of the first cities to secure power from the Hydro-Electric Commission, and consequently attractive rates can be obtained by manufacturers. In addition the city offers reasonable inducements to new industries in the form of free sites, fixed low assessments, low water rates, etc.

Transportation facilities are good with corresponding favorable freight rates, the city being on the main G.T.R. line Toronto to Sarnia. It also connects with the C.P.R., while the C.N.R. will shortly be running there. An efficient electric railway service embraces the surrounding district which is excellent farm land; products of the field are, therefore obtainable at reasonable prices in the city.

WINDSOR, ONT.

THE City of Windsor, situated at the extreme western point of Ontario has enjoyed remarkable success as an industrial centre, and with the adjoining towns of Walkerville and Ford, forms one of the most important and progressive industrial districts in the Dominion. The proximity of Windsor to the United States, and especially to the city of Detroit, Mich., is one of the principal reasons for the rapid development which has been experienced in recent years. Its situation from the standpoint of the United States manufacturer who desires to extend his market by locating a branch factory in Canada, is especially attractive. In many cases the manufacturer likes to be as near his home factory as possible in order to give close attention to the management of both plants. The geographical location of Windsor makes it an excellent distributing point, being within easy access of both the eastern and western markets, which combine with good transportation

facilities and competitive rates. Cheap power, another important consideration, is available in the form of electricity and natural gas.

The City of Windsor has taken definite steps to attract and accommodate industries. An Industrial Committee with an enterprising commissioner have been the means of inducing many manufacturers to locate in the city. Since January 1st, 1913, over thirty concerns have established plants here, nearly all being now in operation. Two factory districts have been allotted, No. 1, comprising 40 acres, has already been sold out, while several sites have been disposed of in the No. 2 factory district. The sites are sold to manufacturers at cost price, and concessions are granted in the form of exemption of taxes, free water and light for a term of ten years. The following figures will indicate the progress made during the past three years. Building permits, $392,000 to $1,137,000; assessment, $10,921,950 to $21,262,450; population 17,534 to 22,080.

THOROLD, ONT.

THE Town of Thorold in the Niagara Peninsula, is exceptionally well situated for attracting industries, and has grown considerably in recent years. In 1912 the population was 2,800; now it is 5,000. During these two years the greatest development may be said to have taken place. The chief inducements to manufacturers are cheap power and low transportation rates, the town being located in the Welland Canal, and having connection with four steam railways, and also an electric railway. There are a number of suitable sites, and a low fixed assessment is granted by the town.

Although Thorold has had quite a number of old industries which have been operating for some years, it is only within the last two that the greatest progress has been made, and this is largely through the instrumentality of James Battle, the town's commissioner, backed up by progressive citizens. Pulp and paper making is the principal industry, although there are other important ones will will be seen later. The Interlake Tissue Mill Co., the Foley-Reiger Pulp & Paper Co., the Thorold Pulp Co., St. Lawrence Paper Co., and the Coniagas Reduction Co., are the chief of the older established plants. Since 1912 the Ontario Paper Co., has started operations, followed by Pilkington Bros., Ltd., from St. Helens, Lancashire, England, the largest glass manufacturers in the world. The Beaver Board Co. new factory is nearly completed, and will soon be in operation. The latest industry to locate in Thorold is the Exolon Co., who will manufacture an artificial abrasive.

The Ontario Paper Co.

The Ontario Paper Co., which is located on the Welland Canal, has erected a plant which cost $1,000,000 and uses 10,000 electrical h.p. obtained from the Ontario Power Co. at Niagara Falls, only a few miles distant. There are two large paper machines in the plant, having a capacity of 100 tons of news print per 24 hours, all of which is shipped to the Chicago Tribune by the Rutland line of steamers when navigation is open. A large proportion of the pulp wood is obtained from Anticosti Island in the St. Lawrence River. The pulpwood is **rossed** and shipped in lengths of 2 ft.; about 30,000 cords will be brought to the mill this season. Some pulpwood is also obtained from Northern Ontario. The plant is owned by the proprietors of the Chicago Tribune.

Pilkington Bros., Ltd.

Pilkington Bros., Ltd., of St. Helens, Lancashire, England, purchased 200 acres of land adjoining the town of Thorold. The initial section of the plant is in operation and turning out factory wired glass of the highest quality. It is the intention of the company to build a large plant for making plate glass. The company brought over 100 expert operatives from the St. Helens factory, these being in addition, of course, to the other hands employed. The company are building a model village for their employees, adjacent to the factory which is located on high land and extremely healthy.

The Exolon Company.

The Exolon Co., of East Cambridge, Mass., have started operations on the construction of what will be a large factory for making an artificial abrasive. The "first sod" was turned by James Battle this spring, being the fourth ceremony of this description at which Mr. Battle has officiated within the last two years; not a bad record. The plant will be built in five units, costing approximately $100,000 each. One unit is going forward now, and it is proposed to build two units in 1915, and the other two in 1916. When complete, it is estimated that about 10,000 electrical h.p. will be used. The company has purchased a site covering six acres on the Niagara, St. Catharines and Toronto Railway, and the first unit will be in operation by November 1st of this year. The contract for the steel work has been let to the Hamilton Bridge Co., and the general contractors are Christman & Co., of Hamilton, Ont.

The Beaver Board Co.

The Beaver Board Co., of Buffalo, N. Y., is one of the latest concerns to locate in Thorold. The company has purchased a site covering 23 acres adjoining the town of Thorold, and have erected a large factory for making the product known as "Beaver Board." The factory, which cost $500,000, is nearly completed, and will shortly be in operation, employing about 150 hands in the first instance.

ST. CATHERINES, ONT.

ONE of the principal cities of what is usually termed the Niagara Peninsula, is St. Catherines, which has a population of 16,000, representing an increase of nearly 4,000 since the last census in 1911. There was a settlement at St. Catherines as long as 1797, and exciting times were seen in 1812-14, while in 1824 the first sod of the first Welland Canal was turned and incidentally was the beginning of the material growth of the "Garden City."

St. Catherines is the centre of one of the principal fruit growing districts of Canada, but at the same time has, latterly, developed into an important manufacturing center. Cheap power is perhaps the chief reason for this, as nearby at Decew Falls, is a hydro-electric plant operated by the Cataract Power Co., and capable of producing 100,000 h.p. In order to attract industries the city offers fixed low assessments, water privileges and land grants, the inducements being in proportion to the size and importance of the industry. There is no lack of house accommodation.

A number of well-known firms have established plants here, among the most important being the Canadian Crocker Wheeler Co., Jenckes Machine Co., Whitman & Barnes Mfg. Co., Canadian Yale & Towne, Ltd., Steel & Radiation Ltd., Reo Motor Car Works, etc. The The latest industries to locate are Welch Grape Juice Co., from Westfield, N.Y., and Lord & Burnham, from Irvington, N.Y. The former concern will make a temperance beverage while the latter will make greenhouses and supplies of all kinds. The Welch Grape Juice Co., will build a concrete and brick factory 102 x 102 feet, four stories high and costing in the neighborhood of $150,000.

St. Catherines has gained some prominence in recent years by being the headquarters of the engineering staff of the Welland Ship Canal. This is a national work of great importance and will benefit the city considerably.

(Continued on page 170.)

Hon. David McPherson, M.L.A., died at Halifax, N.S., on August 13, aged 82. Mr. McPherson, who was a shipbuilder and well known in the Maritime Provinces, was born at Jordan River, Shelburne County, N.S., and was elected to the Legislature in 1897.

Securing and Holding Labor in Manufacturing Suburbs

By J. P. S.

With the increase in land values and the double-barrelled taxation accompaniment now so pronounced in our larger towns and cities, the disposition is towards the emigration to and establishment in suburban districts of both large and small industries. To secure in the first instance, and retain labor which has been more or less cradled in and among the glitter of a city's life and attractions is generally the master problem.

THERE has, of late years, been a decided movement on the part of manufacturers to seek locations in the suburbs rather than in the congested districts of our cities. The natural tendency of Canadian cities to grow causes real estate and property values to increase, and thus assessments for taxation, though reasonable enough at the beginning, are almost sure to become more or less inordinate sooner or later. This is not the only objection to the city plant. The higher cost of living and the multitudinous, frivolous opportunities of spending money tend to increase the wages demanded by the working man as well as to decrease his efficiency as an employee.

A large percentage of the desirable class of help has been more or less burnt with the iron of metropolitan attractions, so that a plan to make the suburban workshop a place of contentment for them by supplying the created want is bound to prove a failure. The man of this type is usually in the search of novelty, and hence something unusual or different from what he has become accustomed will often be equally effective in holding him. The more desirable mechanics demand, not so much the levity as the more substantial of urban comforts. To them the furnished apartments, the restaurants and the rapid car services have become as the necessities of life, and are among the most difficult for the manufacturer unaided to supplant with the means at his command. A great deal can be accomplished in this connection by a little co-operation on the part of the municipal authorities, many of whom are willing to go some considerable length for the mutual good or local industries and themselves.

The Size of the Pay Envelope.

One of the greatest drawbacks of most suburban organizations is the fact that they expect to pay considerably less for help than the metropolitan plant for the same class of labor. No employer can successfully lower the rate of wages unless he be in possession of other features to take the place of the difference. The writer is well aware of one of the largest Canadian manufacturers whose men receive at least one-fourth less than the employees of many other firms, but such are the ameliorating conditions that the list of employees contains a fair sprinkling of those who have been with the firm for from thirty to fifty years, and many of these have temporarily left the service and come back.

There is a class of men who adapt themselves easily to the suburban factory conditions and surroundings. These are the men who are trained and brought up, so to speak, in the plant and make it their lifework. Their disposition creates no serious problem, and, as far as the management is concerned, an adoption of the system as far as is practicable will greatly simplify the help question. This is the natural outcome of suburban conditions where the worker is not so subjected to the excitements and amusements of city associations whic htend towards uneasiness and discontent.

The home bred man, who is a sticker and a hustler, is an acquisition in every sense of the word, and the error largely committed in Canada is that of going too far in this direction. What we need more than any other country is "new blood." The acquiring and holding of this new blood presents such problems that it is often neglected even in the urban centres.

Effect of Labor Scarcity.

The great scarcity of labor during 1912-13 brought forth no very wonderful systems of procuring or retaining help other than increasing wages. Some manufacturers gave this increase directly, while others donated it in the form of a provisional bonus that could be withdrawn as soon as the condition of labor stringency was relieved. Such methods can have no permanent good effect, and, even if carried out in the best spirit, cannot but embitter the feelings of the workmen against the so-called heartlessness of corporations. A system which exhibits no personal consideration for the workman who firmly believes himself to be supporting it, cannot retain the most valuable help, no matter where the industry is located.

The problem of holding help in the suburban plant is becoming less difficult of solution each year. The same mediums of education are more and more being made equally available to the manager and the mechanic. Practical education is without doubt one of the strongest antagonists of the excesses and allurements of city life, and if technical and other educative books and papers could be made easily procurable in the homes connected with the suburban factory, another large section of desirable help would also become easily procurable to the organization.

The technical press is not alone in this work. The home journals, childs' welfare leagues and other mediums rapidly growing in influence, are surely beginning to make their influence felt, with the result that the thinking man who has the prosperity of his family at heart will make his home if possible 'mid healthful suburban surroundings. These influences are to be encouraged. Up till recently the congestion of work in the manufacturing centres has been such that if the workman desired that his family enjoy the country advantages to the smallest extent, he must leave his employment and take his people to live on a farm. This, the opposite extreme is, in many cases, equally undesirable. The suburban shop would greatly assist such men as these, and men who are possessed of such desires are certainly desirable help.

Is there any tangible reason why suburban plants cannot devote as much time and effort to making their plants attractive as those of the metropolis are doing every day? It is a very significant fact that one of the greatest sufferers during the labor market stringency already mentioned was a plant that is approached by roads that stalled automobiles several times during last winter. Many of the employees walked back and forth over these same roads every day. Is it likely that these men will be most self-respecting and most desirable employees? A great many men associate suburbanism with cow stables and hog pens, and the sight of this factory would not be inclined to reform their way of thinking.

City Comforts in the Suburbs.

With the help of the present-day mechanical and sanitary appliances, there is no reason why city comforts and utilities cannot be enjoyed by the suburban mechanic. It is not reasonable to suppose that the employee who gives the greatest part of his mental and physical energy to the advancement of his employer's interests will have enough left each day to perform the chores of the average farmer. In many cases, suburban locations can be chosen so as to give the workman most of the home advantages of the city and a plot of ground large enough to swing a hammock in,

besides with the minimum of expense. It must be borne in mind that the better mechanic demands a certain grade of living and surroundings, and if these are not provided the man, once procured will only stay long enough to acquire the necessary "stake" to move out.

In the city these necessities are provided for by a part of the taxes which the manufacturer must pay the municipality, and for this reason the average manager has failed to take them into consideration when moving to the suburbs. The employer of the outskirts must assume to a certain extent at least the responsibility for which the civic government is well paid by his city contemporary. The extent to which this is required, of course, depends upon the class of work carried on. The demands of a cement mill, for instance, would be insignificant when compared with those of a machine tool works. In any case, it will be found that if judgment be exercised, living conditions can be made better for the workman in the suburbs than in the city, and the "living expenses" of the factory can, at the same time, be made much less.

The Personal Element.

The most attractive feature of any position from the workman's point of view, provided the wages are at all reasonable, is the consideration shown him by the officials of the firm. This does not mean the latitude of misdemeanor permitted or the loosening of proper discipline in any way, but the removing as far as possible of the systems and rules that make him feel very much like the machine he operates. It will be necessary for the officials of the suburban plant to exercise more of the personal element and less of the commercial spirit in getting the best efforts of the best men. They must make up, largely by influence and example, for that which is furnished in the city by the policeman, the civil engineer and others.

The greatest tendency to be guarded against is stagnation, which is already all too evident in some of the institutions of our small towns. The guardian of the company's interests against this condition is first of all the manager, and the responsibility for its prevention rests upon his subordinates in order of their importance. This is largely offset in the city plant by the continual influx of strange mechanics with fresh methods and new ideas. In the suburban plant this must be combatted by the influx of proper literature, competitive methods and the spirit of an energetic management.

Development of the Power Building Feature

By Lycurgus Carson

While large manufacturing concerns are, of course, most in demand by our municipalities, it has not been forgotten that smaller industries are also worth while. To encourage these latter, with in most cases limited capital, or which is at least insufficient to purchase land, build and equip a plant, the laudable expedient of providing a power building where several small concerns may locate is being quite generally adopted.

OF the many plans adopted by municipal governments for the purpose of nurturing young industries and attracting others already developed, the power building idea is worthy of considerable favorable comment. This institution is essentially a building constructed to accommodate a number of small industries. It is built at public expense, and so arranged that partitions can readily be placed anywhere desired to accommodate works of different sizes and requirements. All provision is made for the attaching of line shafting and the setting up of machinery as well as arrangements for heating, light and power.

The building is let out to small industries in sections to suit, and at reasonable rentals. The plan, as has been worked out by municipal authorities, is not a direct revenue producer, the rentals being so gauged as to pay expenses and sinking funds only. A plant of this kind was projected in Montreal by a private corporation, but is not yet in operation, and its value as a private enterprise has not yet been demonstrated. The scheme is said to have originated in the Middle States, where it has been customary for small firms to club together for the purpose of erecting a central building and installing a power plant. The mutual benefits of such co-operation were evident, particularly as the power units in those days consisted mainly of cumbersome and expensive steam engines. Although the advent of the efficient electric motor has much reduced the power advantage, the benefits accruing from the common building are becoming still more pronounced, particularly in the larger cities, where land values make individual enterprise almost prohibitive.

The lack of capital prevents many small enterprises that may, in time, become great, from getting a start. Numbers of young industries have found that the greatest capital cost is the cost of land, building, and power plant. The efforts of embryo factories may be most readily seen in the younger Western provinces, where the struggle with the cheapest building construction, wasteful second hand power units and unattractive surroundings calls loudly to the practical altruistic sense of the observer.

In Montreal, Toronto and some other large Eastern cities, the idea is unconsciously carried out under very adverse conditions. A large number of old and tottering buildings, whose usefulness as offices and warehouses has long ceased, are now rented to small industries, such as clothing factories, instrument makers, engraving companies, etc. In most of these the condition of the building confines to very narrow limits, the amount of power and weight of machinery that can be installed. Even under such circumstances, the system has proved successful, and structures that would otherwise have to be demolished are, in this way, made to pay dividends.

Reform of the Manufacturing District.

The ramshackle effect created by the economical systems of building adopted by small industries, to say nothing of poor heating, lighting and sanitary conditions, would be largely done away with by a municipal power building. The higher status of labor conditions will eventually lead to a better class of work-people that cannot help but be an indirect asset to the city. Industries which depend more or less upon market conditions for their existence, are rarely in a position to build and equip creditable plants of their own and, unless some such provision is made for them, their presence will always be more or less detrimental to the health and appearance of their chosen location.

There are a large number of institutions, such as mechanical experts and specialty manufacturers, whose product is necessary and valuable, and who employ a high class of mechanical help, and who must rent premises of some kind. Such enterprises invariably find it not only necessary to procure a location, but to make the best of a floor space that was never intended for manufacturing purposes. This feature is usually accepted by the land lord with some satisfaction, as the expense of moving is some assurance that he will retain his tenants without serious difficulty.

In locations where cheap electric power is not procurable, the economy of coal or gas consumption should strongly appeal to all patriotic citizens. Small engine units are wasteful, both in fuel

and attendance. The greatest difficulties encountered with the smoke nuisance are in the small plants where the best appliances for its prevention cannot be installed. The fewer and larger the power plants, the more easily this evil can be combatted. Again, many factories require steam for heating and others use it for power only. When it is understood that the same steam can be used for both purposes with little greater cost than for one alone, the folly of installing a plant for a single service is evident. In the power building, the variety of requirements of different lines of business makes possible the most efficient use of fuel. Aside from these large savings, the aggregate of the small ones, such as boiler inspection fees, insurance, etc., will be found to go a long way towards paying the expense of operation of the plant.

Practical Working Examples.

The apartment house has become exceedingly popular among certain classes of people, and is regarded in prosperous localities as a gilt edged investment. The modern apartment house is much more attractive and sanitary than the private homes of the class of people that inhabit them. Although the comparative cost of construction is much greater, the co-operative establishment can, under favorable conditions, give more for the money than the private house. If this can be accomplished in co-operative expense, how much more successful should be mutual support in the production of income.

The municipal power building project, though young, has been tried out and is in operation in several Canadian cities, including Calgary, Lethbridge and Walkerville. Many objections have been raised to its adoption, and have been satisfactorily surmounted. The fault most commonly advanced is that the peculiarities of many enterprises are such that they cannot be housed in a single building. This can be easily overcome by grouping the different concerns in several buildings, with a central power, light and heating plant. The plan followed by the larger manufacturing companies in segregating their foundries, smith shops, machine and woodworking departments, is a practical solution of this question.

The obtaining of the best shipping facilities, both by water and rail is impossible for small concerns without united effort. The large corporations can build docks and sidings equipped with the most efficient handling machinery at their own expense, and such is the volume of their business that these investments may be directly profitable. These advantages can readily be made available to the younger industries in the power building groups. In many places the railway frontage requirements have made it necessary for the small factories to follow the tracks far outside the limits of the cities to which they belong. The sidings, in most of these plants, are not enough used to prevent rapid natural deterioration, and constitute a substantial addition to the overhead expense. The teaming cost of plants without sidings is often equal to the railway freight on their products.

Any means of bringing the industrial part of a town more or less under municipal control is certain to greatly facilitate the governing of these institutions for their own and the general good. The city government must necessarily assume a large number of responsibilities that are difficult to place among a number of segregated institutions. The obligations of sanitation, waste, proper business methods, etc., are much more likely to be fairly met by the municipality than by a small industry which is struggling for existence.

The nurturing of young enterprises is an important branch of the public duty. The elaborate outlay required to carry on a manufacturing business has done much to bring about the trust and the monopoly with their many evil accompaniments. The best cost, wage and other conditions most affecting the public, are brought about and retained by the efficient competitive systems which are best encouraged by the municipal power building. The protection of the smaller and weaker plants from the dominance of the larger masses of capital is best accomplished by providing them with a means of co-operation that will enable them to put up a fair fight for existence.

INDUSTRIAL DEVELOPMENT OF NEWFOUNDLAND.

IN the past fifty years the cod-fishery flotilla of Newfoundland has doubled in number and quadrupled in tonnage. She has maintained and succeeded in the seal-fishery when Dundee and Halifax have abandoned it, and she is now prosecuting it with splendid steamships and reaping a bounteous harvest every spring. She enterprised the modern method of whale-hunting before Canada attempted it, while her herring fishery became so important as to compel England and America to resort to The Hague tribunal for an arbitrament upon issues arising out of it. Her bait industry became so pivotal that her enactment to regulate it, reduced the islets of St. Pierre-Miquelon to beggary, and re-established herself in the European markets from which bounty-fed competition had almost driven her.

A Generation of Progress.

Within thirty years Newfoundland has built 1,000 miles of excellent railway, provided a fleet of twelve coastwise steamers tapping every section of the island of Labrador, and superior to anything of their kind in Eastern Canada, set up 2,500 miles of telegraph lines, erected eighty lighthouses, and doubled the outlay on the various public services by which the mass of the people benefit directly. Her exports have grown from $5,000,000 to $15,000,000, her imports being in the same proportion and her revenue from $1,000,000 to $4,000,000.

The material prosperity, too, of the people has been enhanced in a still greater degree. She has overcome the consequences of a fire that devastated St. John's in 1892, causing a loss of $20,000,000, with only $5,000,000 of insurances, a bank crash that nearly beggared her two years later, and the vicissitudes of the fishing industry in recent years, with a loss of millions of dollars of local capital. Yet the latest statistics show that the savings secured in her banks and debentures total $15,000,000, while the investment in fishing and other enterprises is enormously in excess of this.

Rich in Minerals.

Fish is no longer the mainstay of Newfoundland. The smelters of the Dominion Steel Works at Sydney are fed with ore from Belle Isle, near St. John's. From there 1,500,000 tons were taken last year, and President Plummer, at the recent meeting of the Steel Company, stated that ore could be sold at a profit of $1 a ton, while experts estimate the deposits to contain 3,635,543,360 tons. Other minerals are also abundant and her forests are immense. It is expected that soon the island will be the home of many manufacturing enterprises, each town with its 5,000 to 10,000 persons.

Branch railroads are even now being enterprised to tap sections as yet unsupplied with this progressive auxiliary, the dredging of shallow harbors is being undertaken that the prosecution of the fisheries may be made more convenient, and added stimulus is being imparted to education, the handmaiden of all real advancement.

Marconi received in Newfoundland his first pulsations across the ocean, and the island will yet be the great clearing house for the wireless traffic of the world. The airship man is also casting a speculative eye on Newfoundland, and when he prepares himself for his first overseas flight he will ascend from her island coast.

Toronto, Ont.—It is announced that the Massey-Harris Co. will close their plant on August 22, for an indefinite period on account of the unsettled conditions caused by the European war, and the cutting off of the German, French and Russian markets for their product.

Specific Industrial Opportunities for Manufacturers

Continued from page 165

BRITISH COLUMBIA OPPORTUNITIES.

THE natural advantages of the Fraser River estuary from a commercial point of view cannot help but impress one who makes a personal investigation. Those who would examine it from a critical viewpoint must seek to judge it upon such considerations as proximity to markets, its labor conditions, availability of supplies, etc., and not upon the features with which Nature has endowed it.

One section, miles in extent, embraces a number of islands and a portion of the mainland as level as the sea, and but a few feet above its level at high tide. This land is, although marshy in places, lends itself easily to building purposes as is attested by the number of good roads and other structures which have existed for a long time. The several branches of the river form numerous fresh water basins where ships discharging cargo automatically rid themselves of barnacles and other objectionable marine growths. The Fraser River carries a large volume of water to the ocean, and, although it originally contained impediments to navigation, these, engineers contend, can and are being removed with comparatively little trouble and expense.

To the north and south the land rises in gentle slopes naturally forming residential districts which, for superb natural scenery, are rarely surpassed. This northern part already forms the southern suburb of the city of Vancouver, the importance of whose shipping is well known. The most reasonable line of the city's rapid growth is in this direction, so that the district will be fairly populous in a comparatively short time.

Climatic conditions are mild and such as allow the carrying on of operations in factories very nearly the year round without the expense of artificial heat. The usual objections to mountain seashore climates, namely dampness, is no doubt present, but it is maintained that one becomes much more easily acclimatized to this than to the more rigorous climates of the central and eastern provinces.

The mineral and timber resources of British Columbia are vast and accessible, involving a large percentage of those required in the average manufacturing processes. In fact, available manufacturing sites are few in comparison to the quantity of certain kinds of raw material procurable. The markets have, for some time been more or less confined by the mountain barriers to the Province, but with the introdnction of two more transcontinental railways and the continual improvement of grades, the rapidly increasing population of the northwest, is becoming more and more dependent upon the products of the mountain province. The possibilities of the Pacific Ocean in this respect are obvious. It is plainly the duty of the provincial direction of affairs to see that transportation, labor and other advantages are on a par with the great natural industrial endowments of this favored province.

PETERBOROUGH, ONT.

THE progress the city of Peterborough has made is evidence of its suitability for manufacturing. The population is over 22,500, and the increase in population between 1901 and 1911, as shown by the Dominion Census, was 63 per cent. The census also showed that the percentage of increase in the products of the factories in Peterborough from 1890 to 1910 was greater than in any city in Ontario. The value of these products per head of population in 1910 was $579.14, which was only slightly exceeded by three other cities in the Dominion.

Peterborough has the advantage of being centrally located between the two commercial centres, Montreal and Toronto, and has direct railway connection with them by the Canadian Pacific and Grand Trunk lines direct to the Georgian Bay. It thus is on the main arteries of traffic to the Northwest by both the rail and water and the all-rail routes. The Grand Trunk branches out in four different directions from the city, and besides having the direct Montreal-Toronto line of the Canadian Pacific, the new Georgian Bay and Seaboard line of that railway runs from here, placing Peterborough closer than Toronto to the Northwest. As an indication of the service and traffic, twenty-five passenger trains go out of Peterborough daily.

This city is also on the Trent Waterway, a series of locks and short canals connecting navigable rivers and lakes, which is being built by the Dominion Government, and will give water communication with Lake Ontario and the Georgian Bay. The section which opens it to Lake Ontario is all under contract and nearly completed. The River Otonabee, which runs through the city, and connecting waters, furnish abundant water power, and electric current is delivered to the factories at very low rates. Peterborough is surrounded by an excellent agricultural and dairy district, and the cheese market held here fortnightly during the season is one of the best in the Dominion. Manufacturing sites, with shipping facilities and civic conveniences, are available, while labor of all kinds is readily obtainable. The workmen are largely home owners and interested in the city. While Peterborough has the conveniences and attractions of a city, expenses are lower than in the larger centres, and the cost of labor is less. One of the attractions here to mechanics and other workingmen is the beautiful river and the attractive lakes close to the city.

Among the industries which have located and been built up here, are the Canadian General Electric Co., employing 1800 hands, the mills of the Quaker Oats Co., of Chicago, the English Brinton Carpet Co., and many others. The DeLaval Separator Co., of New York and Poughkeepsie, one of the best known and strongest companies in its line, Henry Hope and Sons, of Birmingham, England, and the Vermont Marble Co., of Proctor, Vt., each selected Peterborough for the location of their Canadian factories.

MOOSE JAW, SASK.

MOOSE JAW began to take on the appearance of a thriving town in 1901, the population then being 1,500. This has increased more and more rapidly each year, until now (1914) the population reaches 30,000.

As a grain and milling centre, Moose Jaw hold an unique position, being in the very heart of the greatest wheat belt of North America. During 1912 there was a total acreage under crop in Saskatchewan of 9,184,814 acres and from this 237,278,446 bushels were harvested. In 1913 the total acreage under crop in the province was 9,673,125, from which 243,513,384 bushels were harvested.

Surrounded by such a vast and fertile grain-growing country, Moose Jaw is the natural four-milling centre of Central Western Canada. One plant, the Robin Hood Flour Mills, is turning out 2,300 barrels of flour per day and 500 barrels oatmeal. Besides this, the mill contains a porridge oats plant, cornflake plant, grain drying plant, and their own cooperage for making the barrels in which the flour is shipped. 135 men are employed by this company. The capital invested in this plant is $800,000. The Moose Jaw Flour Mills is now erecting a flour mill, which will cost $350,000, and which will have a capacity of 1,500 barrels flour daily. It is expected that this plant will be in full operation next week.

Gordon, Ironside & Fares, meat-packing plant, located in the city, is one of the most up-to-date packing plants in Canada. There are 190 men employed and the daily killing capacity is 3,000 sheep, 3,000 hogs and 350 cattle. The initial in-

vestment in the plant and sales equipment amounts to over $1,500,000. The International Linseed Co. is erecting a flax mill, and has taken out a building permit to the amount of $750,000. Their plant is being erected on the ground immediately adjoining the Government elevators. This mill, when completed, will have a daily capacity of 8,000 bushels of flax. Electric power is supplied to these industries by the city at from 1¼ to 1½ cents per k.w. hour.

The Saskatchewan Bridge & Iron Works are located in Moose Jaw, and carrying on the business of erecting bridges and general iron working. The plant and equipment represents an investment of $500,000. The C. P. R. have their divisional point for Saskatchewan established here, and their investment at this point represents over $5,000,000. They employ 2,500 men in and around Moose Jaw, and the pay roll amounts to over $250,000 per month. There are here sixty-seven miles of trackage, the yards being the third largest individually-owned trackage yards in the world. Besides the C.P.R., the C.N.R. and G.T.P. have lines running into and out of Moose Jaw. The Street Railway Co. is now operating on fourteen miles of trackage, giving a service to all central parts of the city.

MAIN STREET, LOOKING NORTH, MOOSE JAW, SASK.

The educational facilities of the city are second to none in the Prairie Provinces. There are seven schools, collegiate institute and the Moose Jaw College, where the youth of the city receive their education, up to the preparatory course for the university.

Unlike many other cities of Western Canada, Moose Jaw's real estate, it is claimed, has never been boomed, the values steadily increasing without leaps and bounds, and the "wild cat" subdivision man has never played an important part in the city. With its strategic position as a shipping centre, the bounless acres of fertile wheat lands surrounding the city, and the unlimited resources of the Province of Saskatchewan, the future of Moose Jaw as a great industrial centre seem assured.

CALGARY, ALTA.

RATING fifth among the commercial cities of Canada, Calgary offers to those who are seeking locations for factories the advantages derived from its geographical position, its cheap and varied sources of power, and its well supplied labor market. As an assembling point for raw materials it has the benefit of three transcontinental railways. As a distributing centre, with ten main and branch lines radiating throughout the 125,000 square miles of trade territory, the city possesses splendid opportunities for serving a rapidly developing market demanding the various manufactured goods used in city and town, in field, forest, or mine.

Much of the railway mileage entering Calgary traverses a country which is and will be pre-eminently devoted to grain growing. When the Panama Canal is in full operation and the double-tracking of the Canadian Pacific Railway is completed from it to Vancouver, a goodly portion of the grain crop of Saskatchewan will here join that of Alberta en route to the markets of the Orient or to Europe via the Panama Canal. The Dominion Government, in preparation for this, has now called tenders for the construction in Calgary of an interior terminal elevator, having a 3,500,000 bushel capacity as its first unit. Transportation facilities, low-priced grain and cheap power are the prime factors in the successful manufacture of grain products, and Calgary seems to possess these.

Within two years Calgary has become the premier cattle market west of the Great Lakes. Cattle, hogs and sheep to the value of $14,000,000 passed through the city stockyards in 1913, while hides to the number of nearly 200,000 were sent to Eastern tanneries. It has been discovered recently that there is hemlock bark in abundance within easy shipping distance of the city, the bark of the Western or Washington hemlock yielding 184 lbs. more tanning per cord than the bark of the Eastern tree, and next to milling and meat packing there is an excellent opportunity for one or more tanneries. Industries subsidiary to those utilizing raw materials at their primary sources will naturally be prepared to take advantage of proximity and establish themselves close by.

Calgary has, therefore, special inducements to offer both large and small manufacturers. Power is derived from the hydro-electric system of the municipality and sold to manufacturers at $26 per horse-power per annum. Natural gas is supplied at 15 cents per 1,000 cubic feet to manufacturers, and good steam coal may be purchased for $2 per ton.

Oilfields.

Adjacent to Calgary are the Southern Alberta oilfields, where a hundred companies will soon be drilling for oil, with the prospect of repeating the strike of the Dingman well a few weeks ago, when almost pure gasoline was tapped and rose 2,000 feet in the well. Expert geologists express the opinion that this will prove to be one of the most wonderful fields yet developed. Canadian, British and American capital in millions is already invested for development work, and the outcome promises a commercial and industrial forward movement, compared to which the past few years, phenomenal though they were, will be but an incident. In three years Calgary's population increased 130 per cent.; bank clearings, 83 per cent.; assessment, 245 per cent.; Customs receipts, 246 per cent.; Post Office receipts, 188 per cent.; and there were erected new buildings to the value of $41,921,985. To large manufacturers the city offers factory sites, power, light and water at cost.

A modern industrial building will soon be placed at the disposal of manufacturers starting in a modest way and requiring leased floor space. This building, being erected from municipal funds at a cost of $250,000, is the first of its kind to be built and operated as a municipal enterprise.

REDCLIFF, ALTA.

THE town of Redcliff is situated about 180 miles south-east of Calgary, on the South Saskatchewan River, and on the C.P.R. Redcliff, although of recent growth, being incorporated in 1912, has already a population of 3,000, with an assessment of approximately $7,000,000. The town has developed into an important manufacturing centre, considering its comparatively small population, principally on account of the abundant supply of natural gas, which can be obtained at a cost of 15 cents a thousand feet. Suitable clay for making bricks and allied products is also obtained in the district, which has led to the formation of several companies engaged in this industry.

The foremost industry is the Redcliff Brick & Coal Co., which was established in 1912, and was followed closely by the Redcliff Pressed Brick Co. and the Redcliff Clay Products Co. Another important industry is the Alberta Ornamental Iron Works, capitalized at $200,000, and manufacturing principally bronze and ornamental iron work. The Redcliff Rolling Mill & Bolt Co. is one of the most recent industries. The company has laid down a well-equipped plant, with a capacity, when working full time, of 40 tons a day. The prospects for an industry of this description are good when the district develops to a greater degree.

One of the latest industries to be established is the Redcliff Motors Co., who make commercial cars for delivery purposes. The Alberta Shoe Mfg. Co. have built a large factory for making shoes. The factory is equipped with modern machinery, but has only quite recently started operations. A knitting factory is under construction.

LETHBRIDGE, ALTA.

LETHBRIDGE is the central commercial and supply point of Southern Alberta. The city is served by eight arms of the Canadian Pacific Railway, and the construction programme of this railway for 1914-1915 gives Lethbridge a largely increased commercial importance. The new line of about 450 miles between Lethbridge and Weyburn, Sask., now under construction, will considerably shorten the mileage between Winnipeg, Port Arthur, St. Paul, and all other Eastern gateways, and Lethbridge, while the completion of the Canadian Pacific Railway line through the Crow's Nest Pass to Vancouver in 1915 will make the route from Winnipeg to Vancouver through Lethbridge and the Crow's Nest pass shorter than the route through Calgary and the Kicking Horse Pass. The new transcontinental line thus formed through Lethbridge will be notable, not only for shorter mileage, but for lower grades. The C.P.R. has added some eight miles of track to its Lethbridge yards during the past year. Lethbridge is spoken of by the traveling public as being the most beautiful of all the prairie cities. It is clean and sanitary. Its well-kept parks and boulevards merit the admiration of all.

The municipality of Lethbridge owns and operates all of the public utilities including a coal mine. The cost of production for mine-run coal for 1913 was $1.19 per ton, while electric power is furnished by the city on a cost basis ranging from $13 per h.p. per annum up. The municipality also owns and operates a ready-made factory, conveniently located and with every modern improvement in which floor space is leased to small industries at low rental. Lethbridge is the first city in Western Canada to adopt the commission form of government; three commissioners with defined responsibilities administering all the municipal affairs. The production of Lethbridge coal mines for 1913 amounted to an average of 4,000 tons per day. The city affords ample opportunities for the investor in manufacturing and jobbing of many and various lines.

THE PAS, MANITOBA.

THE PAS is the southern terminus of the Hudson Bay Railway and at present time, work on the terminus is proceeding. This consists of station, roundhouse, shops and forty tracks to accommodate 4,000 cars. As the construction of the Hudson Bay Railway is going ahead, The Pas, with its population, meantime of 2,000, and situated at the junction of the Opasquia and North Saskatchewan Rivers, will be the distributing point of the Anglo-Canadian commerce and is likely to become a great commercial and industrial centre.

Timber, minerals, fish and furs is plentiful. The Finger Lumber Co.'s plant represents an investment of $1,000,000 and employs 500 men. The mineral wealth is unknown to a large extent, as the country has not been prospected, but copper has been found in rich values in Wintering Lake district and a valuable find of gold has been made at Beaver Lake. The only inlet to these rich fields is via The Pas, where the prospectors can outfit with everything necessary. Fishing is in its infancy, but the unlimited supply will shortly develop into a valuable industry. Sturgeon, salmon, whitefish, pickerel and goldeyes are plentiful. Fur-bearing animals abound, and fur-trading is a leading industry. Beaver, martin, fischer, muskrat, lynx, bear, otter, mink, ermine, foxes (white, silver, black, blue and mixed varieties), are among the fur-bearing animals caught.

There are openings for a canoe and launch factory, a sash and door factory, an abattoir, and brick and tile yards, a rich clay bed, suitable for brick, sewer tile and pottery having been located close to The Pas.

MEDICINE HAT, ALTA.

IT is probably a fact that the average manufacturer who located in Eastern Canada, Great Britain or the United States does not realize the substantial progress that industrial enterprise has made in some parts of the Canadian West. He may have heard now and again something about it, or more likely some of his travelers in scurrying after business, have found that, in some respects, at least, some Western Canadian cities are beginning to supply the local and district needs in the manufacturing line. Usually, he is in a state of blissful ignorance of what has been and is being done industrially west of the Great Lakes.

Among the cities and towns of Western Canada which have made steady progress in manufacturing during the last two or three years, possibly none stand out more prominently than does Medicine Hat—the city located about midway between Winnipeg and Vancouver on the main line of the C.P.R.; the place that is unique in many other respects, and is to-day one of the exceedingly few points where progress is being made industrially and municipally during this readjustment year of 1914. When it is realized that to-day there are half a dozen factory-owners actively busy on their construction programmes in Medicine Hat; that said industries can secure natural gas at the nominal price of one cent per thousand cubic feet for industrial purposes; that there are sites of suitable size on railway trackage at cost—which is nominal; that the water supply is wholesome; that electrical energy is priced as low as one cent per k.w.h. in quantity by the up-to-date municipal power plant—together with a few other advantages—he may well sit up and take notice. Here is a combination which the average resident of Medicine Hat, and the manufacturers already located here, claim cannot be beaten anywhere in Canada, East or West.

Industries in Medicine Hat.

To-day upwards of twenty factories are in operation in Medicine Hat, steadily manufacturing goods and shipping them all over the prairie provinces to points less favorably located and blessed — and thus helping those places to get manufactured articles cheaper than if shipped from Eastern Canada. In addition to the score or more of factories now operating in Medicine Hat, several others are now under construction, besides those that have signed contracts to erect factories. Every industry in Medicine Hat uses natural

gas and there is a coal mine with 77,000,000 tons just outside the city limits.

Clay Working.

Naturally clay working takes a prominent place in the industries of Medicine Hat, with some establishments of outstanding importance. For instance, the Alberta Clay Products Co., with an investment of some $700,000, manufactures 87 different shapes of building block, hollow tile, drain tile, pressed brick, etc., and has furnished thousands of carloads of its product to the different cities of Manitoba, Alberta and Saskatchewan, and is still doing so. Recently, however, the company has taken up more actively than previously the making of salt-glazed, vitrified sewer pipe, of a quality that has evoked praise from the municipal engineers of the cities of the Western prairies. The Medicine Hat Brick Co., which has an investment of about $200,000, is to-day turning out an average of 100,000 wire-cut, stiff-mud brick each ten hours. It is one of the large concerns of the district.

Flour Milling Centre.

Another prominent feature of industrial Medicine Hat is its selection by Canada's greatest flour milling concerns for the location of their Western plants. It was chosen, of course, for the logical location and the economical power costs, together with proximity to the Pacific Coast, where a good trade is being built up with the Orient and Australia, with that via the Panama Canal looming up in the foreground in such a way that it promises to be no small factor.

Three large milling companies are located here. The Ogilvie Flour Mills Co. have had their million-dollar plant in operation in Medicine Hat for about a year, with a capacity of 2,000 barrels daily, the mill being large enough to turn out 4,000 barrels each twenty-four hours. A 500-barrel oatmeal mill is on the programme for next year. This company has elevator capacity to care for 1,300,000 bushels of grain, including the 500,000-bushel grain tanks here and the twenty-seven country elevators in the surrounding districts.

On June 1, the Lake of the Woods Milling Co. acquired for $300,000 the plant, good will, business and elevators of the Medicine Hat Milling Co., which had a capacity of 1,000 barrels daily, and was established here ten years ago as a small grist mill with 100 barrels daily capacity. Immediately the Lake of the Woods management began alterations and improvements to cost about $100,000 for the purpose of increasing the capacity to 2,000 barrels daily, the elevators being trebled in size, and the warehouse also being enlarged.

Within the last month the Maple Leaf Milling Co. started construction on a 3,000-barrel flour mill, the elevators to be of a size to hold 500,000 bushels of wheat or other grain. The structure will be similar to that of the Ogilvie concern here, and a large number of men are now being given employment on the work of construction. At first the capacity will be for 1,500 barrels daily, the additional machinery for double that amount to be added later. It is announced that the mill would be completed in time to handle at least a portion of the 1914 grain crop.

In addition to the above, Messrs. Fraser and Ness, of Ottawa, have a contract with the city for the building of another large flour mill, though probably not as large as the others.

Other Factories.

Medicine Hat is a place of diversified industries as well as substantial ones. It is not dependent on one or two lines. Some 50 or 60 different articles are made in the various factories, and the variety continues to increase each year. Briefly, here are some of them:

The Alberta Rolling Mills Co. manufacture almost every kind and variety of blacksmiths and other merchantable iron, including twisted reinforced rods for heavy concrete work, and the Medicine Hat Nut & Bolt Works started a short time ago, is also turning out an excellent product. One of the busiest places in the industrial district is the factory of the International Supply Co., who are makers of gas and oil-well drilling machinery and supplies. They also contract for boring wells. Two other iron working establishments that have made good and are doing an excellent business are those of the Alberta Foundry & Machine Co. and the Medicine Hat Pump & Brass Mfg. Co., there being a steady demand for the goods they manufacture.

The Canada Cement Co. is building a mill to cost about $2,500,000, which will handle 4,000 barrels of cement every 24 hours. They have already spent upwards of a million there. The Medicine Hat Radiator Co. has construction well forward on its factory to cost some $75,000. The J. H. Tabor Candy Co. is building a two-storey brick factory. The Dominion Sanitary Fountain Co. is proceeding with the construction of its building, while the Murdoch McLeod clothing factory is expected to start work at an early date. The industries now under construction will cost well up to three million dollars.

WHITBY, ONT.

WHITBY is the junction point of the main line of the Grand Trunk, with its double track between Montreal and Chicago, and the northern division of that railway running to Lindsay, Orillia, Peterborough, the Muskoka and Kawartha Lakes country. The building of the C.P.R. new lake front line, now just coming into operation, gives Whitby the full benefit of connection with that great railway system, at present the only completed transcontinental in Canada. It will provide a direct service with the National Capital, Ottawa, and to Montreal. The Canadian Northern Railway will, when completed, become the third transcontinental of Canada, reaching Whitby by means of the Toronto Eastern, a subsidiary of the Mackenzie-Mann system.

Inducements Offered

Cheap electric power, the purest of filtered water from Lake Ontario, and hundreds of acres of low-priced land along the trackage of railways in their several courses through the town, afford admirable industrial sites, which for the present are offered free to manufacturers locating in Whitby. There are also highly favorable conditions as to tax exemption, etc., that invite the favorable attention of manufacturers in the United States and elsewhere looking for branch factory locations in Canada.

OWEN SOUND, ONT.

OWEN SOUND is the principal port on the Georgian Bay, and is the headquarters of the Dominion Transportation Co., the Georgian Bay fleet of the Northern Navigation Co., and of the Chicago, Duluth & Georgian Bay Transit Co. It was a lake terminus of the C.P.R. fleet until that company moved to Port McNichol.

Owen Sound was incorporated in 1857, and has grown steadily, the population now being rather more than 13,000, with an assessment of over $6,250,000. As a residential place, it is particularly desirable, especially in summer, when the natural beauty of the city and surrounding district is seen at its best. From a geographical standpoint Owen Sound is well favored, it being an eminently suitable location for factories, on account of the facilities offered for shipping goods to both Eastern and Western markets at competitive rates, having two railroads, the C.P.R. and G.T.R., in addition to the water routes.

A further inducement will be available in about twelve months time in the form of hydro-electric power. At Eugenia Falls, 36 miles distant, the Provincial Hydro-Electric Commission has decided to develop a water power capable of producing 5,000 h.p., which will be a valuable asset to the town, enabling manufacturers to obtain cheap powers for operating their plants. Owen Sound has already a steel foundry, malleable iron and grey iron foundries, basic industries, which invariably help in attracting others.

HAMILTON, ONT.

SINCE 1910, over 40 factories with an invested capital of over 15 million dollars have located in Hamilton. For the four years previous to 1910 the growth in population was 10,678, while for the four years since 1910, it has been 30,587. Building permits for the four years previous to 1910 were $7,760,047, while for the four years since 1910 they total $18,461,135.

Among the largest industrial acquisitions may be mentioned: The Oliver Chilled Plow Works, of South Bend, Ind.; the National Fireproofing Co., of Pittsburgh; Standard Underground Cable Co., Pittsburgh; Boston Insulated Wire Co., Boston; Grasselli Chemical Co., Cleveland; National Steel Car Co., Passaic, N.J.; Willys-Overland Co., Toledo, Ohio; Dominion Steel Foundries Co.; Canadian Porcelain Co., Rochester; Mercury Mills, Victor Saw Works, Springfield, Mass.

The city refuses to have anything to do with bonus-seekers and believes that a plain statement of facts will appeal more to a concern worth while than the offer of a free site.

A few years ago, practically little attention was paid to all the important matters requiring careful consideration in the proper location of a factory. The matter of successful factory location is one which commands the attention of experts, and those cities which have much to offer in the matter of advantages for manufacturing are the ones which are coming to the front as industrial centres.

Opinion varies as to what is the direct cause for the tremendous expansion in Hamilton. Apart from human energy and local enterprise and without attempting an arrangement in order of importance the six great agencies which are constantly advancing Hamilton as a manufacturing centre are: Geographical location; competition in transportation facilities by steam, electric railroads and water; unlimited competitive electric power; raw materials; labor and living conditions. To attempt to go into this phase of the question fully would take more space than is at our disposal, but these are the fundamental essentials which must always be met in the successful locating of a factory.

Practically all of the important manufacturing and financial cities of Canada and the United States, including the financial and political capitals of both countries come within the radius of a nights' journey from Hamilton.

SHERBROOKE, QUE.

SHERBROOKE is situated at the confluence of the Magog and St. Francis Rivers, on the main line of the C.P.R., between Montreal and St. John, N.B., and on the G.T.R., Montreal to Quebec and Portland, Me., line. The town was incorporated in 1840, and was raised to the status of a city in 1875; the population is 19,500, and assessment about $10,000,000.

The principal feature from an industrial standpoint is the cheap power available. The city owns and controls 10,000 h.p., which it sells to manufacturers at ¾ cent per k.w., or about $15 per h.p. per annum. Power is obtained from two hydro-electric plants, each having a capacity of 5,500 h.p., while extensions are under consideration. There are also two undeveloped water powers—one on the Magog River and the other on the St. Francis River, which would give a further 6,000 h.p. The city owns the gas plant, gas being sold at $1.25 per 1,000 cubic feet.

Sherbrooke is an important manufacturing centre, among the older established concerns being the Canadian Rand Co., Sherbrooke Iron Works, Jenckes Machine Co., and Canadian Fairbanks-Morse Scale Factory. In more recent years manufacturers in the United States have come to realize the facilities offered by Sherbrooke, with the result that a number have established branch factories there. Among the latest to locate are the Canadian Connecticut Cotton Mills, Ltd., making cotton duck; the Panther Rubber Co., from Stroughton, Mass., and the Whiting Davis Co., from Plainville, Mass.; the latter company make wire mesh for bags and purses.

There are a number of valuable mineral deposits in the district, the most important being the asbestos mines at Black Lake and Thetford, which are world famous. Copper mines and a smelter are located at Capelton, while at Brompton and East Angus are large pulp mills doing an extensive business. The exports from this district, principally to the United States, are asbestos, lumber, platinum, chrome and wood pulp.

DOMINION STEEL CORPORATION AND THE WAR

REPLYING to an inquiry as to how the European war would affect the Dominion Iron & Steel Co. plant, J. H. Plummer, the president, said:—

"We have a considerable tonnage of rail orders on our books, but they are chiefly for shipments by water. The disturbed condition which affects the sending of material by sea and the further disturbance of financial arrangements of our customers caused by the war would seem to make it inexpedient to continue rolling on these orders.

"We already have several cargoes awaiting shipment, and more or less held up by those conditions. We think it probable, therefore, that we shall have to shut down much of the plant, or rather to suspend a major part of our operations for a time until we see more clearly what conditions we have to meet.

"In time of war the general iron and steel industries are usually very active, and that effect is likely at this time to be more marked in neutral markets because the great centres of industry in Europe are all directly involved. It is difficult to say how this would affect us in Canada, but if there is an active market in the United States we shall follow them to a greater or less degree.

"At the moment we are preparing to damp down two of the blast furnaces now in blast, and the open hearth furnaces. The finishing mills can and will be operated so far as orders are obtainable. We have on hand a supply of billets sufficient to keep these in full operation for some months. The demand for coal is unlikely to fall off, and unless our transportation arrangements should be seriously interfered with, this portion of our business will continue without change."

CITY OF TORONTO TURBINE PUMP CONTRACT.

MR. FREDERIC NICHOLLS, president of the Canadian General Electric Co., Toronto, has written Mayor Hocken as follows:—

"Dear Mr. Mayor,—I have just learned that the Board of Control of the City of Toronto, have placed their order for steam turbine pumps, amounting to nearly one hundred thousand dollars, with the Turbine Equipment Co., to be made by the De Laval Co., of Trenton, N.J.

"We on Monday last shut down our pipe foundry because of cancellations of orders by various municipalities throughout the country who are unable to sell their bonds and finance their requirements, and while we have been making very strenuous efforts to keep as many men employed at our Davenport works as possible during this period when there will he so many unemployed in this city, it is incredible to my mind that the city should have placed this order for nearly one hundred thousand dollars with a United States concern when the prices were practically the same.

"The city will have to provide for thousands of unemployed during the coming winter and there is absolutely no reason why it should be sending this amount of money abroad for the employment of United States workmen when we were able and willing at the same price to do the work in Toronto.

"Yours very truly,

"FREDERICK NICHOLLS.

"President."

WAR PANIC DISORGANIZING BUSINESS.

THE principal developments to be noted since a general European war became an accomplished fact, are those in which business interests predominate. A real live panic has got hold of the Canadian people, and as a result there is a tendency in industrial circles for the managements to cut loose, **burn their bridges**, sit tight and conserve their present resources. On another page of this issue much sane advice by the noted economist Sir George Paish, is compressed into small space. One thing that strikes us as regards the situation created by the war, and which may be read into Sir George's statement is that the public weal should at all hazards be conserved.

Industries have without doubt been directly affected as a result of the outbreak, but amid all the panicky pessimism, there is no real outlook to warrant a stoppage of the productive power and income of our country. It is a time more than ever before which puts our **Captains of Industry** in the limelight and on their mettle, and just as we unhesitatingly look forward to the triumph of our Empire in its titanic struggle for right and freedom, we likewise predict that our manufacturers will not fail by their actions and attitude during this crisis to merit the universal commendation of the Canadian people.

WAR BRINGS INCREASED REVENUE.

ALTHOUGH literally speaking, **the time to make hay is while the sun shines**, figuratively, it may be made at any time. We need not lay ourselves specially out for the purpose either, although perhaps as individuals such a proceeding would probably be necessary. Our patriotism, if worthy of the name would, however, be a sufficient deterrent in these stirring times.

While Canadian manufacturers and industrial concerns generally have been more or less adversely affected by this world-involving European War, it is worthy of note that our great public utility corporations are being affected beneficially, a condition of things likely to exist until long after peace is declared and until trade and commerce get back again to normal. The highly satisfactory part of this experience is that no special effort has been made to secure the increased business, therefore no imputation of sharp practice, meanness or lack of patriotism is applicable.

By reason of the war the revenues of certain corporations in Toronto have increased considerably. The Bell Telephone Co. state that calls have increased about thirty-three per cent., the greater number of these extra calls being to the newspaper offices. Towns outside Toronto have also sent in additional long-distance calls, the increase being reckoned at about ten per cent. The lines of the telegraph companies have also been exceptionally busy, their revenue showing an increase of twenty per cent.

The business of the cable companies has increased about ten per cent., although the number of cables was not as large as before. The fact that addresses and signatures had to be given in full has augmented the revenue. Another corporation that has scored heavily is the street railway. The war bulletins and special editions of the newspapers have brought thousands of people down town, who in the ordinary course of events would have stayed at home. It has been estimated that the additional profits of the street-car company amount to some $5,000 per day.

What is true of Toronto is without doubt the experience of the public corporations and municipally owned utilities in the principal cities and towns of the Dominion. As a consequence we think it right that the attention of the various executive bodies who are planning Empire aid in able-bodied men and material, who are taking steps to succor the wounded and dying, and last, but not least, who are planning to keep **the wolf from the door** of homes from whence the bread-winner has gone at his country's call, should be drawn to this phase of the situation so that a share in the profit arising from our Empire's fight for liberty, be forthcoming to further and bring that fight to an early and successful conclusion, and with the minimum of suffering and inconvenience.

This is no time for **hoggishness**, individual or otherwise. Practical demonstration was given a few days ago, here in Toronto, of what individualism can achieve, and the Canadian Pacific Railway Co. management as has been their wont are again to the front with full handed patriotism, an example of corporation generosity. Canada and the Empire expects **every** public utility corporation to do its duty.

INDUSTRIAL NOTABILITIES--No. 48

PHILIP LESLIE MILLER, naval architect and general manager Canadian Vickers, Ltd., shipbuilders, ship repairers, engineers and boilermakers, Vickers Bldg. and Naval Construction Works, 3072 Notre Dame St. Longue Pointe, Montreal, was born in Dundee, Scotland, May 27, 1876, the son of Alice (Waterston) and James William Miller, M.D. He was educated in the High School of his native town, following which he served a five years' apprenticeship with Gourlay Bros. & Co., shipbuilders, also of Dundee. He next spent one year at St. Andrew University.

In open competition Mr. Miller gained a free studentship and Admiralty scholarship, entitling him to a three years' course in Naval Construction at the Royal Naval College, Greenwich, which he completed and qualified at the final examination in 1901.

PHILIP LESLIE MILLER

He was appointed by the British Admiralty to the Royal Corps of Naval Constructors, serving as such for twelve years in the construction department of the Admiralty and of the Royal Dockyards at Portsmouth, Hong Kong and Malta.

He supervised construction of warships on the Clyde on behalf of the British Admiralty from 1908-1911, and was lent by the British Government to the Turkish Government in the latter year to supervise construction of Dreadnought battleships being built in England for the latter. Mr. Miller resigned from this position and from the Royal Corps of Naval Constructors in 1913 to take his present positoin at Montreal.

He married Flora Margaret Baxter, daughter of Arthur Baxter, Blairgowrie, Scotland, Nov. 5, 1906.

His clubs are the Engineers, Outremont and Kanawaki Golf, Montreal, while his recreations are golf and music. He is also a member of the Institution of Naval Architects of Great Britain.

In religion, Mr. Miller is a protestant, and his residence is 164 Crescent Street, Montreal.—Photo, courtesy of International Press.

The General Market Conditions and Tendencies

This section sets forth the views and observations of men qualified to judge the outlook and with whom we are in close touch through provincial correspondents.

Montreal, Aug. 17, 1914.—Another week of suspense has passed and business still remains at a standstill. This, of course, is not other than can be expected because of the fact that military operations are being executed upon such a gigantic scale, therefore decisive developments cannot be hoped for in a short time. All markets are very erratic, and the various firms form quite as varied a number of opinions as to how the war will effect Canada; as a consequence, prices of material quoted cover a wide range, and a like condition exists in all lines of trade. The metal business is completely disorganized.

The general idea, however, is that the German forces will receive a decisive check as soon as a battle on land occurs. This will restore confidence among manufacturers and in financial circles, the outcome being increased business.

Pig Iron.

The pig iron market is no exception to the others, it, too, being in a most unsettled condition. One can form no definite idea of how the European market is, because no quotations are being received. Considerable quantities of pig iron from England are in the country and from this stock the demand is being supplied. England and Scotland import a large amount of ore and this supply is meantime being cut off.

The Steel Market.

The steel market is in much the same condition as that of the pig iron. All rolled sections of steel are commanding a higher price than they were a month ago. No large orders for steel have been received during the week.

Machine Tools.

There have been only a few minor sales reported during the week. This branch of business feels the depressions first and is about the last to recover. The delivery of European tools is still uncertain, but as there are no sales this phase of the situation does not have much effect.

Metals.

The sales here have been low during the week. Tin seems to have reached its high level and has since sagged a little. Copper remains steady. In other metals but slight variation is noted. However, all prices are more or less nominal as the London and New York Exchanges are still closed.

Toronto, Ont., Aug. 18, 1914.—The war in Europe is the principal topic being discussed and it is naturally having an effect on the spirits of the community. Business conditions cannot be said to be any more settled and a considerable amount of anxiety still exists as to how Canada will be affected. Opinions naturally differ on this point seeing that the situation is one that has never been experienced before, there being no precedents to follow. It has been officially announced that the Atlantic trade routes are open for commerce, which will help to allay fears expressed when the trouble started; this will also relieve the situation as it affects our export trade.

Canadian business will be further reassured by the action of the Dominion Government in making arrangements with the Bank of England for the collection of gold at Ottawa until such time as international exchange is again on a working basis. This arrangement will release for export a large amount of material, principally foodstuffs, which had been held up on account of the prohibitive exchange rates which made it almost impossible to finance shipments. Trade with Germany is cut off, which will mean a reduction in our export trade in metals, manufactures of iron and steel and agricultural implements, amounting roughly

to one million dollars. The decrease in Customs receipts on products from that country will be considerable.

It is futile to hazard a guess as to the duration of the war, but in any case it is essential that everybody should be calm and confident in the face of difficulties and as far as possible act in their business relations as if great events were not impending. Let not our confidence be seriously disturbed; otherwise conditions will become worse. The financial situation cannot help but affect trade adversely, but there is no real reason why factories should be closed down and employees laid off, except in exceptional cases. The population remains practically the same and the requirements of the people will not decrease to any appreciable extent. The natural resources of the country do not depreciate and the productive powers of the country should be maintained as far as possible.

We notice that municipal works are being stopped in some places and in others continued. In the former case the works are mostly of considerable magnitude and therefore difficult to finance. Some industries, notably pulp and paper, will benefit while; with others the reverse will be the case. Taking an average, it is possible that the country will not be very seriously affected.

Steel Market.

The situation in the iron and steel markets is practically the same as last week. Comparatively little business is being done, everybody awaiting developments in the war zone. This condition may continue for some time until all fears are dissipated and a more confident spirit permeates the community. The increase in the cost of raw materials and the uncertainty of the sources of supply of some products are causing manufacturers to withdraw all prices and only book orders at prices mutually agreed upon or at prices ruling on date of shipment. This is a natural outcome of conditions which we hope will approach nearer to the normal as soon as the excitement has subsided. The base price on bars, plates and shapes has advanced to $1.20 Pittsburgh. There appears to be a belief in the United States that the war will, at no distant date, cause an increased demand for steel products for export, but when this is likely to happen it is difficult to venture an opinion. Nearly all the countries involved in the war are large exporters of steel products so it is reasonable to suppose that this trade will be transferred for a time to the United States and possibly a share to Canada. The situation is a difficult one to gauge with any degree of certainty, but will be greatly relieved when Great Britain and her allies have got the upper hand and control the area of hostilities.

Pig Iron.

The pig iron market is very quiet but prices are firm. Little business is being done, consumers waiting until the situation is clearer. The pig iron production in Canada is not of very large proportions but the few furnaces that are in operation may possibly benefit by the war as regards their export trade.

Machine Tools.

There is no change in the situation, the machine tool business is very quiet with little prospect of a near future revival. Dealers view the situation with a certain amount of apprehension.

Machinery Supplies.

Little business is being done in machine shop supplies, small orders being the rule to fill immediate requirements. There is a tendency to curtail machine shop operations, which will directly affect the demand for supplies.

Tool Steel.

The demand for tool steel has fallen off in sympathy with other lines, and few orders are being placed meantime. A considerable amount of tool steel is imported from England, while a certain amount comes from Germany and United States. The supply from the two former countries has been cut off, leaving the United States to supply any deficiency. We understand, however, that some dealers have considerable stocks, principally carbon steel, on hand and can supply the market without much difficulty for the time being.

WAR MARKETS.

NOTE.—Owing to the continued unsettled condition of the markets generally, and consequent upon rapid fluctuation in prices, it is impossible to give firm prices in our selected market quotations for many products, as prices on a number of lines are liable to change daily or oftener. The quotations will, however, serve as a guide while at the same time indicating the general trend of the market.

Mechanical Rubber Goods.

The prices on mechanical rubber goods have not been advanced as yet, being made principally from reclaimed rubber. Those lines made from crude rubber are subject to different conditions and have advanced in price, This, however, will not materially affect goods used in machine shops.

Metals.

Considering the abnormal conditions, the metal markets are comparatively steady. Antimony at 25 cents is the only metal to remain at the high figure quoted last week, all other metals have weakened. There is apparently no relief in the tin situation, but the price has dropped to 55c. Spelter is slightly weaker at 5½c, lead 5c, and aluminum 23c per lb. Copper is quiet and price weaker. The demand for most metals is light, as might be expected with present conditions.

Ottawa, Ont., August 17, 1914.—The emergency session of Parliament opened this week. It will be a brief, business session. The situation is too serious for party politics, and the country is in no mood for patriotic speeches. Canada wants action, not words. The Government has its legislation already in shape, so that there should be little delay. There will not be many bills, but they will be important, and will give the Government sweeping and drastic power to deal with any situation which may arise. There will be general legislation giving the Government more authority to deal with the question of militia and naval defences. Approval will have to be secured of some action already taken by the Government.

From the standpoint of the business world, the most important legislation will be that giving the Government power to declare a moratorium in case of an emergency and also authority to deal drastically with the problem of food supply. The bills introduced by the Government will be based on English legislation.

Winnipeg, Aug. 15, 1914. — Speaking generally, the tendency in the West is for those who have been contemplating purchasing machine tools, to delay until conditions in Europe right themselves. Several who had placed orders, cancelled them temporarily. Hand to mouth buying seems to be the general rule, and all orders received are for actual requirements.

Last week saw the arrival of Alfred Martin, representing the John Bertram & Sons Co., Dundas, Ont., for machine tools, and Pratt & Whitney Co., of Canada, for small tools. He has opened an office on the first floor of the Bank of Hamilton Building. The Canadian Fairbanks-Morse Co. recently secured an order fro mthe town of Kamsack, for a pumping and electric lighting outfit, consisting of gas producer, gas engine, dynamos, and pumps.

Metals.

Tin is practically priceless here. A few lots are being sold out of Montreal at 70 cents. Antimony is almost impossible to procure, the market price now being 20c. Copper is one of the few metals which are plentiful. The jump in the price of tin has caused solder to go up 10c., being now quoted at 35c. by local jobbers.

Face the Situation with Courage and Confidence

¶ In view of the events taking place in Europe, which will constitute an epoch of perhaps unprecedented importance in history, we appeal strongly to all Canadian business men and all who hold securities or investments of any kind, to meet the present situation with calmness and confidence. Our first duty, at any cost, is to aid in Great Britain's sustenance and defence, and our next duty, not less important, is to keep the business of the Dominion moving as normally as possible.

¶ "In the unprecedented and critical situation that exists," says Sir George Paish, in the London Statist, "we would make a special appeal to the patriotism as well as to the interest of the investing public.

¶ "At such a time it is of the greatest importance that everyone should endeavor to act as if great events were not impending. Were confidence seriously disturbed business would come practically to an end, and our ability to face the difficulties that may be in front of us would be seriously impaired. Therefore, it is of vital importance that, as far as possible, the events that are now taking place should not interfere with the daily life and the daily work of the nation. Orders should be given, factories should be run, and everything should be arranged to maintain, as far as possible, the productive power and the income of the country.

¶ "Yet for this to be accomplished the situation must be faced with courage and confidence on the part of everyone. Investors must continue to invest, bankers must continue to lend, the Stock Exchange must continue to deal, and everyone, according to his ability, must endeavor to work hard in order that individual incomes, and therefore the income of the whole nation, may be maintained at the highest possible level.

¶ "A little over a century ago, when the nation was at war with Napoleon, its income was a very small one, being less than one-eighth of what it is at present, and in a comparatively short space of time the British people succeeded in raising about £1,000,000,000 of money for war purposes, and so great was their confidence and courage that at the end of the great war, which severely taxed their resources, they were stronger and wealthier than they had been at the beginning."

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News.

Engineering

Brampton, Ont.—The Clinton Motor Car Co. will build a factory here.

Guelph, Ont. — The Canadian Ingot Iron & Culvert Co., will make extensions to their factory.

Essex, Ont.—T. A. Hill is equipping a plant for making and repairing motor cycles and cars.

Salmon Arm, B.C.—J. K. Gardner and W. Thorpe propose establishing a machine shop and garage here. Machine tools will be required.

Toronto, Ont.—Fire did $5,000 damage to buildings and contents of the Standard Foundry Co., at the foot of Jarvis street, on August 11.

Medicine Hat, Alta.—Work is about to start on the construction of the Dominion Harvester Company's plant at Dauntless. Mr. F. S. Ratliff is secretary of the company.

Saskatoon, Sask.—The John Deere Plow Co. has applied to the city commissioners for a water main to their warehouse building on Twenty-fifth street. The company wants the additional water supply to feed a sprinkler system which it intends to install in the building.

Halifax, N. S.—President Harris of the Nova Scotia Steel Co., has announced that as a result of the unprecedented financial situation created by the war it has been decided to close down a portion of the plant at Wabana Mines, and the blast and open hearth furnaces at Sydney Mines have been temporarily stopped.

Toronto, Ont.—Next week work will be started in earnest on the new Union Station. Six carloads of machinery and heavy timbers arrived from Calgary and are now on the ground and will be used in the construction work. The consignment consists of donkey engines, cement mixers and derricks. The Peter Lyall & Sons Construction Co. are the contractors.

Saskatoon, Sask.—A strong committee has been appointed by the Saskatoon Gas & Oil Co. to take charge of the reorganization of the company. The committee was appointed at a meeting held recently. It is composed of the following prominent business men: J. F. Cairns, chairman; D. D. Currie, G. H. Clare, R. F. Preston, S. W. Johns, J. P. Murphy, E. F. Crawford, H. Tupling, Geo. Tupper, Wm. Oliver, C. J. Hanratty and C. G. Locke.

Windsor, Ont.—Cast stone blocks are being manufactured here by the Canadian Zagelmeyer Co., Ltd. This company also owns the patent rights to manufacture the machinery used in making cast stone blocks and they have the entire Dominion of Canada as their territory. Although they have been in operation only a week or so they have already equipped plants in Montreal, Winnipeg and Edmonton. Adam Kolb is the president of the company, Frank Zagelmeyer vice-president, L. H. Walker local manager, and J. F. Kinzinger secretary.

AUSTRALIAN RAILWAY WORKSHOP TENDERS.

Still further additional tender forms, specifications and drawings for equipment required by the Victorian Government Railway Workshops continue to be received from Commissioner D. H. Ross, Melbourne, and are open to the inspection of Canadian machinery manufacturers on application to the Department of Trade and Commerce, Ottawa. Particulars of these requirements, together with the dates on which the tenders close at Melbourne, are briefly outlined thus:—

27189—September 30, 1914—100 steel booms to specifications.

26912— November 4, 1914—60 sets balls and races for turntables

The mail leaving Vancouver (tenders should be endorsed by that route) on September 2, will reach Melbourne on September 28, and the mail leaving Vancouver on September 30 is scheduled to arrive at Melbourne on October 26th.

Porcupine, Ont.—The task of centralizing operations on the group of properties controlled by the Canadian Mining & Financing Co., will commence at once. The twenty-stamp addition to the Hollinger mill has been completed, and will be running almost certainly next month, and then with as little delay as possible the foundations will be laid for the twenty stamps which are to be reserved for the ore from the Acme gold mine, the private property of the syndicate. Alterations will gradually be made to the Cyanide end of the plant all over the mill until it has been converted into a continuous decatation process.

Electrical

Ayr, Ont.—The site on Northumberland street, recommended by an engineer of the Hydro Commission, is now declared unsuitable, though the municipality has purchased the lot. Nothing definite has yet been done about a new one.

Windsor, Ont.—The plant of the Walkerville Light & Power Co. has been disposed of to the Hydro-Electric Commission at a price stated as $85,000. The plant will be taken over at once and operated at higher prices to consumers till Niagara power is ready. It is expected the hydro wires will be ready to deliver current at Walkerville inside of one week. The power plant will then be dismantled and disposed of.

Drumbo, Ont.—Work is being rushed on the hydro transmission line to this town. A substation will be erected here, the location is selected and the work will begin at once. The supplies for the line are all here to be distributed to Plattsville and Princeton, and work will be pushed as fast as possible, and light will be given early in September.

Municipal

Stratford, Ont.—The council has authorized the purchase of a pulmotor.

Hamilton, Ont—Burlington village will extend its waterworks system.

Sandwich, Ont.—The city will make considerable extensions to the water main system.

Stratford, Ont.—The garbage committee has been instructed to proceed with the purchase of wagons for the local system.

Lethbridge, Alta.—The city will complete the high pressure water system which includes a new intake and new mains representing a total outlay of $54,755.

Comber, Ont. — Little interest was manifested in the vote last Monday to expend $4,500 for securing power from

the Hydro-Electric Commission. The vote stood forty-one for the by-law, and one against it.

Newmarket, Ont.—Arrangements are being made for the holding of another public meeting next week in connection with the campaign in support of the proposed Hydro-Electric Municipal Radial Railway from Toronto to Port Perry.

Hespeler, Ont.—Mayor William Kribs and the town councillors have been holding several special meetings in regard to the building of the town hall. The mayor has decided to put it to the citizens of Hespeler to endorse the proposition or otherwise.

Newmarket, Ont.—The town council are most reticent regarding a new industrial concern which it is said intends to locate here. The members met again on August 12 in conclave, but would not make public the results of the meeting. It is believed that the company desire the municipality to guarantee their bonds.

New Toronto, Ont. — In anticipation of the speedy construction of their new $14,000 waterworks system, the corporation are taking over the Grand Trunk and factory service pumping plants. Delivery on the new intake pipe and the arrival of four miles of piping is expected immediately. It is probable that Mimico will ask for a service.

Hamilton, Ont.—Four money by-laws were submitted to the ratepayers last Monday, and all were defeated. It is a very unusual thing for money by-laws to be defeated here, but little interest was taken because of the war. The by-laws were to raise $175,000 for trunk sewers in the eastern part of the city, $50,000 for East and West End Branches of the Library, $125,000 for improvements to the City Hospital and $75,000 for purchase of a stone quarry.

General Industrial

New Westminster, B. C.—The Pacific Chocolate Co., will build a new factory.

Arnprior, Ont.—The Arnprior Felt Co. will build their new factory by day labor.

Estevan, Sask.—Geo. Barr will erect a plant here for the manufacture of sand lime bricks.

Drumbo, Ont.—The Board of Trade is in treaty for a large factory which it is proposed to locate here.

Estevan, Sask.—The Denison Fireproofing Co., of Mason City, Iowa, has secured a site and will build a factory.

Grimsby, Ont.—The Consumers' Box & Lumber Co., will probably rebuild their basket factory, recently destroyed by fire.

Hamilton, Ont.—Permission will probably be given, by the city, to the National Paper Co., who desire to extend their factory.

Kingston, Ont.—The tannery buildings of Davis & Company, were destroyed by fire on August 9. The loss of $80,000 is covered by insurance.

Kingston, Ont.—The employees of the Dominion Textile Mills here were made happy on August 12, by the announcement that the mills would work full time for some months. They have been on three-quarter time.

Nelson, B.C.—Because of the low price of copper and the curtailed market caused by the European war, the Granby and B. C. Copper Companies' smelters are being closed down. The Trail smelter, of the Consolidated Company, which has a large gold and silver output, will continue operations.

Vancouver, B.C.—The B.C. Manufacturers' Association do not expect the present war crisis to affect trade and do not look for a falling off. Secretary J. G. Hart states that all space in the building set aside for the association at the exhibition is already taken up and that many applications received cannot be filled.

Carman, Man.—The building of a plant here for the manufacture of sewer pipe is under consideration, and building operations are expected to commence without delay. The high-grade clays suitable for this industry are located 20 miles west of Carman on the C. N. R. Exhaustive tests have been made, which show that the deposit is a valuable one.

Sydney, N.S.—The Iona Gypsum plant is now in full operation. The opening of this important addition to Cape Breton's many fine industries was made the occasion of a visit by the directors, who made a thorough inspection of the plant. It is the intention of the company to increase the number of men employed as soon as the necessary arrangements can be made.

Preston, Ont.—War now in progress between Great Britain and Germany is beginning to affect the local manufacturers. Two of the factories that have been working eight hours a day, from now out will work only three days a week. The Patterson Woolen Mills announce that from now on they will work only five days a week. This is the first time in 18 years that the mill has worked short time.

Thedford, Ont.—The Board of Trade is negotiating with an American concern which wishes to erect a canning and preserving factory here. The firm selected a site to its liking, and an option has been secured on the property. The matter of a private siding is now being taken up with the Grand Trunk Railway, and it is hoped to have everything in shape for ratification within a few days.

Granby, Que.—The Bell Asbestos Co. of Thetford Mines has closed down owing to the European conflict. This company had its chief market in Germany and Austria. About 400 men are thus thrown out of employment. It was announced that the mines were closed for eight or ten days, but if war continues the period will be indefinite. Other mines will also be greatly affected and it is rumored will be closed. No shipments of asbestos for Europe will now be accepted.

Berlin, Ont.—The industries of Berlin and Waterloo will benefit by the war during the next few weeks. Three local trunk-making factories have received orders from the Militia Department at Ottawa to manufacture 7,000 sets of Oliver equipment, 2,000 rifle buckles and 5,000 rifle slings. Five shoe-making factories will manufacture 20,000 pairs of men's shoes, and a local shirt factory will make up 10,000 service shirts. The entire order must be delivered within the next five weeks. If a second contingent is sent from Canada the order will be duplicated.

Fort Frances, Ont.—With a view to encouraging the establishment of an important and valuable Canadian industry, the Province has granted to Duncan Chisholm, a Toronto capitalist, a concession to erect a pulp and paper mill at Smooth Rock Falls, on the Metagami River, and to expend $1,750,000 thereon. The daily output of paper will not be less than 150 tons, and the inauguration of the concern means employment for at least 250 hands for ten months of each year. The project is under way, and high hopes are held of the ambitious venture turning out a success, in which case it might be the precursor of a greater development of this industry in Canada.

Fort William, Ont.—It is reported that a cleaning and drying elevator will be erected by a group of capitalists represented by N. M. Patterson & Co., who will add the new plant to that already operated by them at the intersection of the three transcontinental railways. The property, containing 880 feet of river frontage, has been bought by Mr. Patterson and his associates at a figure which is said to be in the neighborhood of $60,000. Here will be commenced im-

mediately the first 100,000-bushel unit of what will eventually be a 1,000,000 bushel elevator. The elevator will be equipped with the latest ideas in cleaning machinery, and will be capable of cleaning, scouring or drying grain of all kinds, and will have the advantage of being able to ship direct into vessels.

Tenders

Toronto, Ont.—Tenders are being called for the construction of a bridge on the Don section of the Bloor street viaduct. See issue of **Canadian Machinery** for August 6.

North Vancouver, B.C.—Tenders for the construction of the remaining portion of the Dominion Shipbuilding & Drydock Company's plant at Lynn Creek, will be received until Sept. 1st. The site comprises 140 acres, and the total estimated cost of the project is $5,000,000.

Montreal, Que.—Tenders for the supply and delivery of one seven-passenger touring car, addressed to the Board of Commissioners, will be received until Tuesday, August 25th, 1914. The specifications, forms of tenders and all information required may be obtained at the office of the superintendent of purchases and sales, City Hall.

Wood-Working

Listowel, Ont.—The D. Hibner & Co. chair factory opened up on Monday with a full staff.

Orillia, Ont. — J. R. Eaton & Sons, have completed extensions to their factory and are in the market for woodworking machinery.

Vancouver, B.C. — The Cloverdale Brick & Tile Co. plant at Cloverdale, was totally destroyed by a fire on Aug. 4, which started in the dry kiln. The loss is estimated at $30,000.

Belleville, Ont.—The saw mill at Mud Creek, owned by J. N. Huff, of Highland Grove, was destroyed by fire recently, together with all the machinery with the exception of the boiler and engine. There was no insurance.

Fern Ridge, B.C.—The plant and yards of the Fern Ridge Lumber Co. were completely destroyed by fire recently, there not being a stick of timber left of the several million feet in the yards, or the mill itself. The loss is placed at $150,000, with $100,000 insurance.

Toronto, Ont.—The buildings at Marshall's Lumber Yard, at Davenport road, near Huron street, were totally destroyed by fire recently, the damage being estimated at $10,000. The planing mill was destroyed, as was also another building on the premises with a quantity of timber.

New Westminster, B.C.—The lack of proper fire protection is said to have caused the loss of the $3,500 plant of the Royal Oak Shingle Co. recently. The fire started in the engine room and quickly spread so that the whole mill burned to the ground. The dry kiln and other property near were not damaged. The loss is partly covered by insurance.

Railways - Bridges

Weston, Ont.— Township workmen have commenced the building of a new concrete arch bridge over the Black Creek, on Fifth avenue.

Port Arthur, Ont.—The ratepayers have passed debenture by-laws for an issue of $22,000, for four new street cars, and $40,620 for track extensions.

Brantford, Ont.—Work on the construction of the new steel and concrete bridge for the Lake Erie and Northern Railway has commenced. P. H. Secord & Sons, of Brantford, are the contractors.

Victoria, B.C.—Estimates of the cost of strengthening the proposed Johnson Street bridge to permit of the B. C. Electric Company hauling freight over the two lines to be used by the company and also to widen the structure, were submitted by City Engineer Rust to the City Council sitting as a bridge committee recently. Four alternative schemes were considered, ranging in cost from $360,000 to $392,000. The latter figure allows for the use of fifty-ton electric locomotives.

Lacombe, Alta.—The first gasoline electric railway to be constructed in Alberta is the line now under construction from Lacombe West to Gull Lake, Bentley, and Rimbey, a distance of about 45 miles. It is reported as well under way, over half the distance being graded, and ties being on the ground the full length of the route. Moreover, the rails are in the yards, and one of the cars is now on the way from England. It is fully expected to have the line in operation early this fall.

Building Notes

Montreal, Que.—The Harbor Commissioners will build a warehouse to cost $75,000.

Toronto, Ont.—It is reported that a United States syndicate will build a large hotel near the Union Station. The cost is estimated at $500,000.

Trade Gossip

Brantford, Ont—The Massey-Harris Co. have closed down their plant here for an indefinite period on account of the war cutting off the Russian market.

The Canadian General Fire Extinguisher Co., of Montreal, has been licensed at Victoria, B.C., to carry on business in the Province of British Columbia.

The Whiting Foundry Co., Harvey, Ill., has been awarded a contract for a 20-ton overhead, hand operated, traveling crane, by the Winnipeg Board of Control.

The Turbine Equipment Co., Toronto, has been awarded a contract, by the Toronto Board of Control, for two 24 million gallon pumps for the main pumping station. The price of the first unit is $50,400 and of the second $48,400.

Fraser & Chalmers, of Canada, Ltd., Montreal, have received an order from the Siemens Co., of Canada, for one-188 h. p. Terry steam-turbine, running at 3600 r.p.m., fitted with "**Falk**" gearing, for reducing the speed to 1200 r.p.m., so as to be suitable for direct coupling to a Siemens excited generator. This machinery will be installed by the Corporation of the City of Regina.

Shipyard May Close Down.—It is reported that the Davie Shipbuilding & Repairing Co., of Levis, Que., may shortly close down. This is one of the oldest ship-repairing concerns on the St. Lawrence, and in their drydock many vessels have been overhauled and repaired. There is little work at present on hand, and as immediate prospects are not good, the plant may be temporarily shut down.

The Polson Iron Works, Toronto, last Saturday launched the hydraulic dredge, "Tornado," which is being constructed for the Canadian Stewart Co. The dredge, which is the second of the two 24-inch hydraulic dredges to be used on the Toronto harbor improvements, was christened by Miss Bessie Stewart, daughter of Dr. A. M. Stewart of the Canadian Stewart Co., in the presence of a large crowd.

The Copp Stove Co., Fort William, Ont., state that they have appointed W. E. Raymond to be manager of the company and are making arrangements to enter very extensively into the foundry jobbing business. They will also be in a position shortly to meet all competition along the line of medium light weight, grey iron and semi-steel castings. The

company will make a specialty of sash weights, coal chutes, catch basins, etc. They will greatly increase the capacity of the plant for making stoves, heaters and furnaces.

The Canadian Crocker-Wheeler Co., St. Catharines, Ont., advise us owing to the present unsettled conditions, the rapid increase in the cost of most raw materials, and the uncertainty of all sources of supply, they find it necessary to withdraw all outstanding quotations and to advise customers that prices previously in force are hereby canceled. Orders will be accepted at prices agreed upon or on the understanding that goods will be billed at prices ruling at the date of shipment. Although meantime impossible to foresee what the trend of prices may be in the future, all customers are assured that the company will serve them to the best of their ability as heretofore.

The Canadian Westinghouse Co., Hamilton, Ont., give notice that on account of present unsettled condition of business throughout the Dominion, they are compelled to notify customers that all outstanding prices and quotations on electrical apparatus and supplies unaccepted as at August 14 are hereby withdrawn. The necessity of this course is regretted, but that it is unavoidable, follows from existing financial conditions disturbed by the general European war, from the large increase in prices already registered in several lines of raw materials, and from the uncertainty as to a continuance of supply of various other elements of manufacture consequent on interruption of international commerce.

An early improvement is hoped for on all points, and meanwhile the company will be glad to furnish quotations upon request at lowest figures permissible under the current conditions.

Personal

John Philip Holland, inventor of the "Holland" submarine, died on August 12, at his home in Newark, N.J., aged 72 years.

Anthony F. Cramer, president of the Huetteman & Cramer Co., Detroit, Mich., died on Sunday, August 2, aged 70 years.

A. N. Beer, who has been engineer in charge of the Waterworks Department of the City of Ottawa during the past year, has resigned.

James Carruthers, the well-known grain merchant, and president of ehe Canada Steamship Lines, celebrated his sixty-first birthday last week.

William H. Candlish, who for many years was on the engineering staff of the Montreal Water Works, died at Montreal on August 13, aged 75.

Captain Harry Parsons, a prominent Victoria mariner, successfully passed the necessary examination for a pilot's certificate, and has been assigned to the D. G. S. Malaspina.

C. A. Meadows, B.A.Sc., has just returned from Europe, where he has spent three months investigating improved machinery for wire and ornamental iron work.

Captain Lawrence Thompson, a Victoria navigator, long connected with coastal shipping, has been appointed to act as a special pilot, and has taken up his duties on the D. G. S. Galiano.

Wm. Snaith, of the Thor Iron Works, Toronto, has returned from a five months' absence in California, where he superintended the construction of a number of oil tanks at Oilfields, Cal.

Willis Chipman, C.E., of Chipman & Power, consulting engineers, Toronto, has been retained by the City of Edmonton to report upon the several electric power schemes now under consideration.

W. E. Raymond has been appointed manager of the Copp Stove Co., Fort William, in succession to Fred W. King, resigned. Mr. Raymond has had considerable experience in the stove manufac-

Plant and Equipment Features the A. B. Ormsby Co., Toronto

Staff Article

To even the casual observer it must be amply evident that sheet metal products in almost endless variety are features of industrial enterprise sufficiently important to place them in the very front rank of twentieth century developments. An insight into what is being achieved, both utilitarian and highly ornamental, may be acquired by a careful perusal of the accompanying article.

THIS firm having become associated with the Metal Shingle & Siding Co., of Canada, found that their former premises were too small to take care of the increased volume of business. Their new plant is located in Toronto at the corner of King and Dufferin streets, and is thoroughly up-to-date in every detail. The main building is two storeys high, of brick and with concrete floors throughout. Occupation was had early in November, 1913. A few improvements are being added this season and when these are finished the new factory will be a model of completeness.

Sheet metal has become more and more widely known of recent years and its use, more extensive. Metal is being used in all classes of building as a preventitive of fire. Thus to-day its various uses are almost unlimited. One can easily see then that the product of such a plant as the A. B. Ormsby Co., is of an exceedingly varied nature.

Lines of Product.

The most important lines are as follows:—Various kinds of sheet steel for siding and roofing, and large sheets of corrugated steel. The smaller sheets, steel siding plates are stamped in various designs, more or less ornamental. A large part of the factory is given up to the hollow steel department. Here are made various articles, chief among which may be noted wall panelling, partitions, hollow doors, and interior trim. These products are all beautifully enamelled to represent oak, mahogany and other finishes. In another department steel sash and steel window casements are made. Various grades are produced, from those of plain painted steel for factories and warehouses to the highly decorative variety used in the best class of buildings.

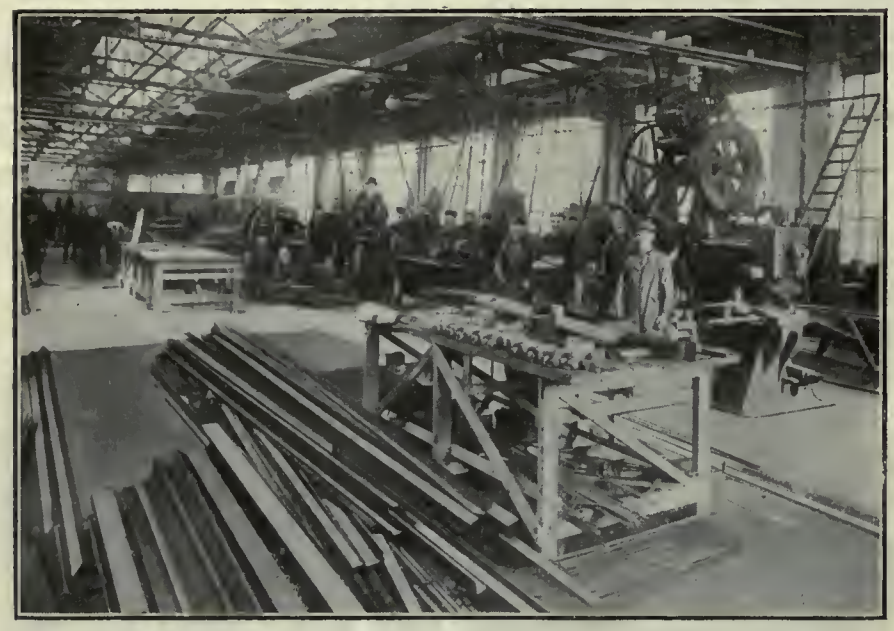
GENERAL OFFICES, KING AND DUFFERIN STREETS, TORONTO.

The Kalamein Department.

The kalamein department is also extensive. This process is used largely for doors, window sash, and mouldings. The method of manufacture is to build doors and sash of good dry wood, laminated to prevent warping or distortion, and to cover them with sheet brass or copper, and any one of a dozen or more colors can be obtained by the proper chemical treatment of the metal. These colors and finishes, thus made, are permanent. A large market has also been created for galvanized iron kalamein work, because it is fireproof and much cheaper

SHEET METAL SHOP, A. B. ORMSBY CO. PLANT, TORONTO.

than hollow steel products. Various woods are used according to the class of work. In the highest grade, mahogany is used, while in the cheapest lines a good grade of white pine answers the purpose. All the wood used is kiln dried to ensure its being thoroughly seasoned and perfectly dry. Still another product of this department is that of revolving doors, and also more or less veneer work. In a general way this comprises the list of products of the factory.



MACHINE SHOP.

The Power Feature.

Nearly three hundred horse-power is used about the plant. This is supplied through various units by Canadian Westinghouse Co., motors. There are in all sixteen motors varying in size from 75 horse-power down to 2½ horse-power. The arrangement makes a very economical installation because the motors only run when the machines they operate, are being used. One motor usually drives a length of line shaft to which various machines are belted, but some of the larger machines have individual drives.

There is also a power house in connection with the plant; it is not under the roof of the main building, however. Here will be found a battery of three return tubular boilers, supplied by the John Inglis Co., Toronto. Two of these boilers are 78 inches in diameter by 20 feet long, and one 72 in. diameter by 16 feet long, being rated at 150 h. p., and 100 h.p. respectively. They are built for a working pressure of 125 lbs. This pressure is required by the enamel ovens which are situated in the factory proper. Atmospheric pressure steam is used for heating the buildings themselves, and from atmospheric to 5 lbs. pressure is used in the dry kilns.

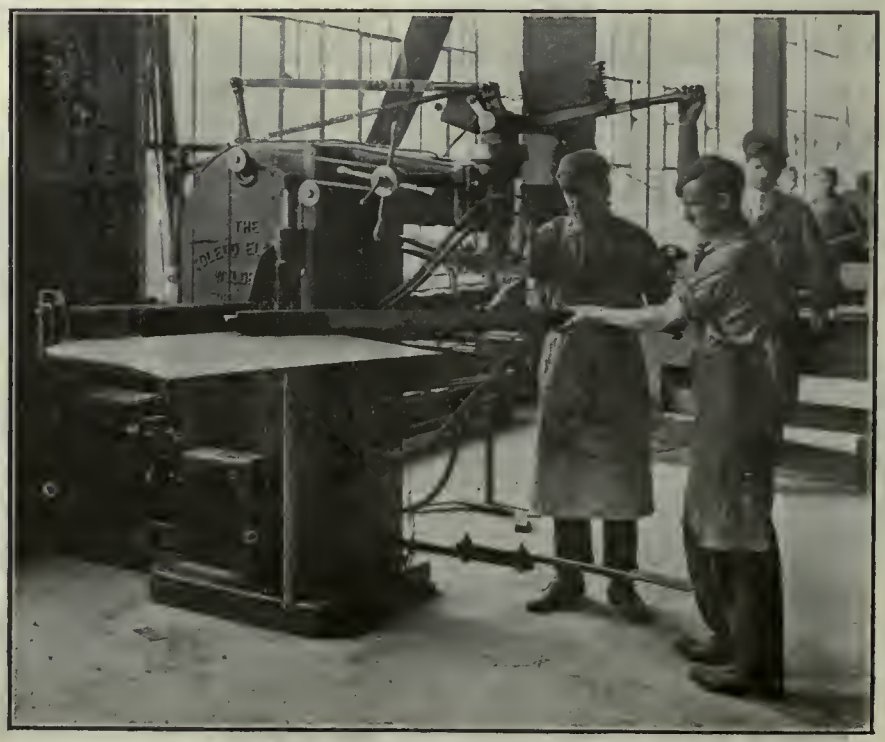
The boilers are so arranged with high and low pressure headers that each or all boilers may be used on high pressure or low pressure as may be required, the steam being by-passed through reducing and controlling valves. It is also possible to take from one boiler 125 lbs. pressure steam for the enameling ovens, atmospheric steam for the heating and low pressure steam for the dry kilns. This also is possible from each or all boilers.

Factory Heating.

The general heating in the factory is that of the vacuum system, all the heating in the different departments being acomplished through radiators placed along the outside walls. There is, however, one exception to this, in the case of the large shop, there being 2 38-in high column radiators and coils of 1½ in. pipe in the monitors. On every unit there is placed a Webster water seal motor valve for controlling the amount of steam which is passed through the radiator or coil. The return lines from the different buildings are carried to a vacuum pump through Webster condenser heads and lift fittings to the 10-12-12 in. **Bawden** vacuum pumps. The vacuum pumps discharge the water of condensation into the receiving tanks, from whence it drains by gravity to the boiler feed pumps, which are 10-16-12 in. The boiler feed pumps operate through an automatic control.

The general heating scheme is arranged as follows: A 12-in. low pressure header is carried to an 18-in. wrought iron low pressure steam distributing header, from which steam is carried to every building in a separate line. Each building and every separte steam line is controlled with its own valve on the header. Thus the engineer in charge has complete control of the entire radiating system from the boiler room.

The boilers are operated under induced draught, the stack being only forty feet high. A 120-in **Canadian Sirocco** standard steel plate fan of extra heavy steel, has been placed on top of the boilers, and is direct connected to a 7-in. x 7-in **American Buffalo Forge** vertical engine.



SPOT WELDING MACHINE IN HOLLOW STEEL SHOP.

It is possible through this medium to carry any draft required up to as high as 1½ in. water gauge. This also allows the use of a cheap grade of fuel. At present there is being burned a half and half mixture of hard and soft coal screenings, with practically a total elimination of smoke.

In the enameling ovens where a pressure of 125 lbs. is required there is placed in each oven two coils of 1 in. extra heavy pipe, each coil having a header of 3-in. extra heavy wrought iron pipe, tapped out for the 1-in. pipes which are screwed into it. The returns are carried back through **Mason** side lug high pressure steam traps to the receiving tank in the boiler room. These coils make it possible to raise the temperature in the ovens to 300 degrees Fah. very quickly.

STEEL SASH SHOP.

The plant has been so designed that three additional storeys may be added at any time, and the present equipment will be amply sufficient to take care of same.

Machinery Equipment.

In the carpenter shop and kalamein department are to be found a large number of wood working tools. These have been supplied largely by the Canada Machinery Corporation, Galt, Ont., and consist of edgers, groovers, band saws, rip saws, planers, etc. A 30 h. p. motor driving a Canadian Sirocco suction fan carries the saw-dust and shavings from each machine to the power house where they can be blown into the boiler fireboxes and burned, or into a vault from which they can be stoked into the boilers by hand when desired.

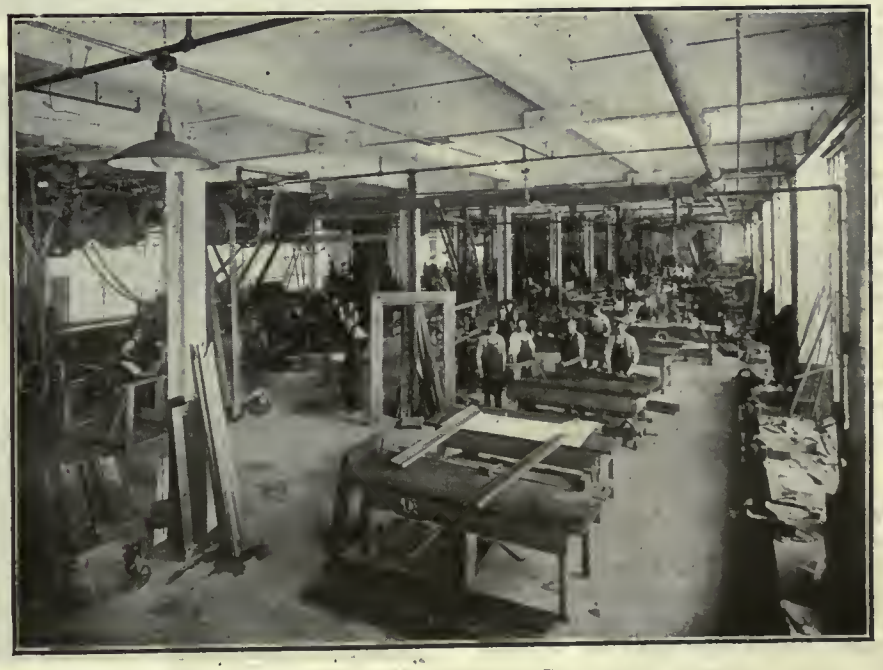
In the machine shop, a 75 h.p. motor is connected up to a Pokorny & Wittekind air compressor. The firm making this machine is located at Frankfort-on-the-Maine, Germany. Their product varies widely from the prevailing American design. This machine has one cylinder of two bores, and by an ingenious differential piston it does duty as a two-stage compressor. An inter-cooler is mounted on the top of the cylinder which is horizontal. The valve in the compressor is mechanically operated and is known as the Koester piston valve gear.

An extremely ingenious device is fitted to the compressor to prevent it from putting excessive pressure on the receiver. When the pressure has reached one hundred pounds per square inch, the device closes the air intake valve and the compressor runs idle until the pressure becomes sufficiently reduced; it then takes up its load again. The capacity of the compressor is 320 cu. ft. of free air per minute, its stroke is 15¾ in., the bore of the large end of the cylinder is 18⅛ in., and the compressor is run at 145 r.p.m. The air intake is in the roof. This intake leads from the compressor and consists of an 8-in pipe with a T fitted on the end, in each end of which a short nipple is screwed. To each nipple an elbow is fitted with open end down. Two large galvanized iron funnels are fitted over the ends of the elbows and screened.

Air is used in the sand blast system which is a Hoevel unit. Both the compressor and the sand blasting unit were supplied by R. M. Fotheringham, Toronto, who has the Canadian agencies for both firms. Air is also used in the hoist in the paint shop, and in the pneumatic tools in the machine shop. These latter are all Cleveland pneumatics. In the power house the air is also used for blowing out boiler tubes and for removing ashes. The use of the air is of course more or less irregular and this varying load causes the automatic cut out to work frequently. As this compressor was somewhat unique in design and seems to have given excellent satisfaction, its description at some length was thought advisable here.

Machine Shop.

In the machine shop is installed a very complete range of machine tools consisting of lathes, shapers, planers, drill presses, punches, shears, and several automatic machines which execute certain operations to parts of the standard steel sash. Among the interesting machines are two triple combination plate shears,



HOLLOW STEEL SHOP.

punches, and bar and angle cutters, purchased from the Wiener Machinery Co., of New York. These machines have solid steel frames permitting compactness which makes them most suitable and economical for crowded shops. Without change of tools they are capable of splitting plates of unlimited length, cutting flat bars, shearing off rounds and squares, cutting and mitering both right and left hand angles and tees at any degree, and punching plates and structural material either of web or flange form. With interchangeable tools, beams, channels, Z bars, etc., can be cut. The punching tools can also be interchanged for coping and mitering tools.

The following firms are among those which supplied the shop equipment:—

Canadian Westinghouse Co., Hamilton, Ont.

Canadian General Electric Co., Toronto, Ont.

Loy & Nawrath, Newark, N.J.

Hendey Machine Co., Torrington, Conn.

Walcott & Wood Machine Tool Co., Jackson, Mich., whose Canadian agents are the General Supply Co., of Canada.

W. F. & J. Barnes Co., Rockford, Ill.

Toledo Electric Welder Co., Cincinnati, O.

Fitchburg Machine Works, Fitchburg, Mass.

The John Bertram & Sons, Co., Dundas, Ont.

The Brown Boggs Co., Hamilton, Ont.

The V. & O. Press Co., New York City.

The Farrell Foundry & Machine Co., Waterbury, Conn.

Geo. A. Ohl & Co., Newark, N.J.

Superior Machine Tool Co., Kokima, Ind.

The Tubular Rivet & Stud Co., Boston, Mass.

E. W. Bliss & Co., Brooklyn, N.Y.

H. W. Petrie, Ltd., Toronto, Ont.

The W. P. Davis Machine Co., Rochester, N.Y.

The Stahlwerk Oeking Co., Duesseldorf, whose American agents are the Wiener Machinery Co., New York.

The Barnes Drill Co., Rockford, Ill., whose Canadian agents are the Canadian Fairbanks-Morse Co., Toronto.

The R. McDougal Co., Galt, Ont.

The Canada Machinery Corporation, Galt, Ont.

The Canadian Fairbanks-Morse Co., Toronto, Ont.

The John Steptoe Shaper Co., Cincinnati, Ohio.

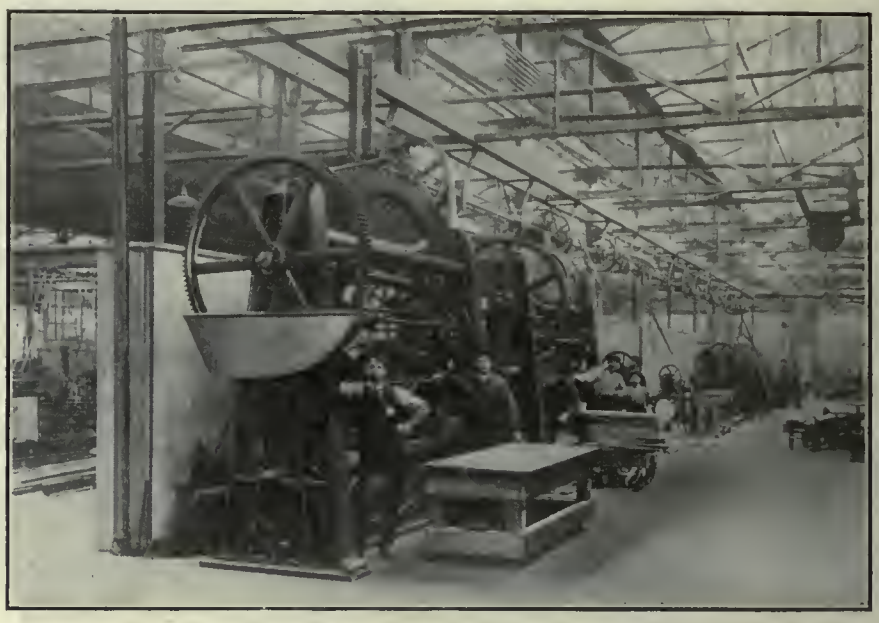
Stock Room

In the receiving department a stock of about one thousand tons of steel is usually kept. There is of course a large variety of sections in the stock, but as the sections are all small, the total represents a rather large quantity. A great deal of this material comes from the Carnegie Steel Co., but the Hamilton branch of the Steel Company of Canada, have installed rolls that will turn out some of the required sections. As a result they are now enjoying a portion of the business.

Process of Manufacture.

The rolled steel sections are stored in receiving sheds conveniently located near the company's railway spur. This raw material enters the shop and is cut to length. Then it passes from machine to machine through the successive operations which make it a finished part. The various sections each pass through their respective series of cutting, punching, shearing, etc., and are passed on to the assembling department. Here the pieces are riveted and welded and a finished sash turned out.

The various ideas and tastes of architects are constantly bringing new orders of a distinctly original character, and to make dies and to machine the tools required to manufacture these special articles keeps a staff of machinists busy. Their work is of a very general character and often requires considerable ingenuity to accomplish it.



SHEARING AND FORMING DEPARTMENT.

Sand Blasting and Pickling.

There are two small departments of no little importance located at the entrance to the storage and packing department. These are the sand blasting room, and the pickling room. In the sand blasting room the hollow steel work is cleaned and finished preparatory to being enamelled and grained. This is done by means of a spray or blast of sand working under high pressure. The

HOLLOW STEEL SHOP SHOWING THE ROLLING MILLS.

blast plays on the comparatively rough steel product and the result is a smooth polished surface which is pleasing to the eye.

The sand blasting room is a brick building well lighted from the roof and sides, and is equipped by the Hoevel Sand Blast Machine Co., of New York. The equipment consists of a sand blast pressure tank, an automatic sand conveyor, and a bucket elevator with a dust arrester. The sand after leaving the pressure tank strikes the castings and falls through a grate into a trough containing a screw conveyor. The latter delivers it to one end of the trough where it is raised by the bucket elevator and discharged through a device that separates the dust from the blasting sand which goes back to the sand blast pressure tank. The power necessary to operate this circulatory system exclusive of the pressure-tank is about 1 to 1½ horse-power; an unusually small power consumption for this purpose. The dust created in the blasting-room is exhausted by a fan and passes through a sand arrester which intercepts all particles of sand while the lighter dust escapes to the atmosphere. For installations where the amount of dust is considerable, or objectionable the Hoevel Sand Blast Machine Co. provide an air filter for the exhaust which effectually prevents any dust passing into the atmosphere.

ASSEMBLING HOLLOW STEEL DOORS.

In the pickling room the copper and brass kalamein work is cleaned in acids and the various finishes obtained by submerging the pieces in different solutions. Near the power house, but in a separate building is the paint shop where the steel frames and sashes are dipped. The dry kilns are also located near this building, while a little further along the garage is located, over which is the dining hall.

Overhead Runway.

The whole of the plant is served by means of an overhead runway, supplied and erected by the Herbert Morris Crane & Hoist Co., Ltd., Toronto. Sections of the runway are carried out over the railroad sidings in the form of swing jib cranes, so that a load can be picked right off the car and taken into the warehouse at one handling. **Morris** chain blocks and trolleys run over the whole system, and will carry cases, bales, bars and other supplies up to a ton in weight.

An interesting feature of the runway is to be noted in connection with the finishing of the steel sash product. After the latter is completely manufactured it is taken into the paint shop to receive a protective covering. The sash is suspended by means of special two-wheel trolleys, on which it is taken to a rising and lowering section of the track, located immediately over the paint dipping tank. This section is controlled by a **Morris** pneumatic spur-gear hoist, which is fitted with automatic stops to prevent overwinding. A slight depression in the track beam retains the trolley in a central position during the dipping process. Afterwards the trolley with its load is run over the draining board, where surplus paint drips off. All the switches in this overhead runway are of the **Morris** fixed type without moving parts.

Employees' Welfare.

Throughout the various departments of the plant the comfort of the employees has not been forgotten. Clean sanitary wash rooms are provided as also are lockers which were made in the shop. The sides of the buildings throughout have been constructed as far as possible of glass to give the best natural light. The monitors also are largely of glass. The machines are all located so as to make the very best use of the excellent light.

The factory is also equipped with powerful incandescent electric lights in frosted globes and fitted with powerful reflectors. A large number of smaller incandescent lights are distributed about the various departments. The windows in the monitors and side walls all open, so that a very efficient ventilating system is thus aided during the summer months. Throughout the whole plant and in the yard there is a monorail system for the rapid and convenient handling of heavy materials.

The offices are located in the northwest corner of the main building. They occupy both storeys and are both pleasant and comfortable. The drafting room is on the second floor and is exceptionally well lighted. The whole factory is modern and up-to-date in every respect, being of course fireproof.

An automatic sprinkler system is installed and provision has been made for further extension of this system. An underground tank is to be added as also a steam driven pump. Bennett & Wright, Toronto, installed the sprinkler equipment, as also the heating and ventilating systems. The plant enjoys an exceptionally low rate of insurance and when this further addition to their sprinkler system is completed their rate will be as low as can be obtained.

There is in Toronto and elsewhere a great deal of building in progress and this plant is receiving a fair share of the business connected therewith. The future outlook is also good as there are a number of proposed buildings upon which construction will no doubt soon be in progress. When running to full capacity about at least 500 men are employed.

Speeding-up a Machine Shop by means of an electric drive has been proved possible at a shop maintained by the city of Chicago for repair work on pumping and other apparatus for the water department. Formerly the shop was driven by a slide-valve steam engine through intricate line shafting. No-load tests made showed that 53 per cent. of the power generated was required to drive the line shafting and idle pulleys. A motor-generator set was substituted for the steam engine, with the result that the line-shaft losses have been reduced from 53 to 10.8 per cent. Furthermore, it has been possible to increase the speed of the line shafting a third, and the men in the shops have unconsciously speeded-up correspondingly.

Boiler Makers' Convention — The American Boiler Manufacturers' Association will hold its 26th Annual Convention in New York City, Sept 1 to 4, inclusive, with headquarters at the Waldorf-Astoria hotel. All boiler, tank and stack manufacturers and fabricators of steel plate, also manufacturers and representatives of materials and supplies used by boiler manufacturers are invited to attend the convention.

Electrical Equipment for Motor Driven Machine Tools--II.

By C. Fair *

The importance of motor drive for the machine shop is every day becoming more evident and more thoroughly appreciated, and it is worthy of note that in practically all new industrial plants where power is required, electrically-driven machinery has been installed. Little trouble is now experienced with either motors or control for the ordinary type of machine tool, due largely to a better understanding of the situation between machine builder and user.

BETTER drives are possible now than formerly, due to the motor speed range obtainable, to the decrease in size of motor per horse power, to motor characteristics which specially adapt them to the work which they are to do, to more perfect balance of the rotating parts at high speed; and, to a certain degree, to improvements in gears which allow higher speeds without excessive vibration and noise, and to the many recent improvements in control.

Present Requirements Exacting.

Much more exacting requirements of both motor and control are now demanded. Motors driving machines reversing ten times per minute and operating twenty-four hours per day are now not unusual. Duty cycles that were impossible to meet only a short time ago are now not only practicable but common. With the great variety of motors and controllers now on the market, and the large quantity sold sometimes without the motor manufacturer even knowing for what service they will be used, it would be surprising if trouble did not occasionally occur.

Much of the success of a motor-driven machine depends on its control. Magnetic control, which is coming into more general use somewhat complicates the control situation. While the possibilities of magnetic control are infinitely greater than the older types of control, likewise the chances for misapplication are greater. However, as the characteristics of the different types of control become better known these complications will disappear.

The increase of the number of individual motor-driven tools is due fundamentally to the facts, as has been shown, that the tool can do more work, do it better, and do it cheaper.

Motor Drive Application

Increasing discrimination is being exercised in applying motor drives. When the work of actually equipping a factory with motor drive is undertaken, it is necessary to study the conditions of operations, which vary greatly with the product manufactured. The arrangement of a factory may be entirely different if many motors are used instead of a few groups. Simply the difference in the position of a number of the tools may greatly facilitate the handling of material.

In general, the most satisfactory electrical equipment for machine shops, using a large number of motors, would be one having available both a-c. and d-c. distribution; a-c. for all constant speed machines and d-c. for adjustable speed machines. In the smaller shops, with rare exceptions, the choice of motors would depend upon the current available, which in the majority of cases would be alternating current. The very size and product of the small factory makes a proper layout a comparatively simple matter, while in larger factories skill and ingenuity, are essential to obtain the most advantageous equipment. The standard motor of to-day will answer for the majority of the machine tools, although special motors are in some cases necessary. When equipping tools with individual drives, the controlling apparatus as well as the motor should be attached directly to the tool whenever possible. In the case of portable tools this, of course, is a necessity.

A graphic recording wattmeter in circuit with a tool is of value in efficient management as it not only tells the actual power consumed by the machine, showing whether or not the tool is properly motored, but it also shows whether the tool is operating at its maximum rate, by registering the time of unproductive cycles or the length of time the tool is idle. By analysis, the cause of the lost time may be discovered and a change of operating conditions can be made with a corresponding increase in production.

Choice of Motors.

Table I. will, in a general way, aid in the choice of motors. The great variety and the size of tools of the same name make it necessary in a general list, such as this, to double-check a number of tools. It must be kept in mind, however, that various circumstances, such as size and roughness of work, and flywheel capacity, etc., may call for radical departures in the choice of motors, this list being compiled to meet average conditions.

*Squirrel cage rotor.

†Squirrel cage rotor—high starting torque.

‡Slip ring induction motor with external rotor resistance.

§Does not apply to reversing motors.

*Power and Mining Engineering Department, General Electric Co.

Shunt motors, for instance, are used in the following cases:—When work is of a fairly steady nature, when considerable range of adjustment of speed is required as on lathes and boring mills, and on group and lineshaft drives, etc.

Compound-wound motors are used where there are sudden calls for excessive power of short duration, as on planers (not reversing motor drives), punch presses, beinding rolls, etc.

Series motors should be used where speed regulation is not essential, and where excessive starting torque is required, as, for instance, in moving carriages of large lathes in raising and lowering the cross rails of planers and boring mills, and for operating cranes, etc., but not where the motor can be run without load as through a clutch, or belt that might leave its pulley, as the motor would run away if the operator failed to shut off the power.

When in doubt as to the choice of compound or series motors of small horse power, the choice might be determined by the simplicity of control in favor of the series motor.

The alternating-current motor of the squirrel cage rotor type corresponds to the constant-speed, shunt, direct-current motor; but with a high-resistance rotor it approaches more closely the characteristics of a compound, direct-current motor. It is understood that the variable-speed machines checked in Table I. under the alternating-current squirrel cage rotor column have the necessary mechanical speed changes.

The slip-ring induction motor with external rotor resistance would be used for variable speed, but this must not be construed to mean that it corresponds to a direct-current, adjustable-speed motor, as it has the characteristics of a direct-current shunt motor with armature control. The self-contained, rotor resistance type could be used for lineshaft drives, and for groups when of sufficient size.

Multi-speed, alternating-current motors are those giving a number of definite speeds, usually 600 and 1,200, or 600, 900, 1,200 and 1,800 r.p.m., and are made for both constant power and constant torque. These motors would be used where alternating current only was available, and where the speed ranges of the motor, together with one or two change gears, would give the required speeds. These motors should, however, be used with discretion, especially on sizes above six-horse power.

The adjustable speed, a-c., commutator brush-shifting type of motor with shunt characteristics would, on account of high cost, be used mostly where an adjustable speed motor was highly desirable and where a-c. only was available and where there were not enough machines calling for adjustable speed drive to warrant putting in a motor-generator set.

Adhering to Standard Motors.

An important feature in the selection of motors, and one that is often overlooked, is the adherence to the use of standard motors, and by standard motors is meant standard armature shafts as well. The importance of maintaining standard armature shafts will be recognized when it is pointed out that by such an arrangement spare armatures are reduced to a minimum. In emergencies it is often possible, where spares are not carried in stock, to replace the armature or even a whole motor by one from an idle tool, or from a tool of relatively less importance at the time. Also, of course, stock motors can be supplied promptly by the manufacturer and shipments materially improved if special shaft extensions are not called for. That special features in a motor are sometimes desirable, is true; it may so happen that the advantages from some special feature in the motor may more than offset the disadvantages referred to, but in cases where these features are thought necessary they should be carefully considered before final decision.

In the early days of motor drive before the present great variety of sizes and speeds of standard motors were obtainable, many special features were thought necessary in the motor to make it adaptable to the tool; special frames, shafts and speeds were required, and little thought was given to the interchangeability of parts. In fact, tools which only a few years ago it was thought necessary to drive with special motors are to-day driven by standard motors, and as a result are easily and quickly repaired. It is therefore easy to recognize in these early equipments the responsibility for part of the existing idea that special features in the motor are still necessary for tool equipments. Many of these special features required for the early drives are now recognized as unnecessary, and to-day the tool builder in the majority of cases builds his tools ready for attaching standard motors.

The old prejudice existing against the electric motor, which was mostly a mistrust due to a lack of familiarity with its operation, is rapidly dying out, and to-day motors are found driving machines in shops of every description.

Choice of Control.

Equally important with the choice of motors is that of control. In selecting the control its adaptability, its accessibility to the operator, the method of attaching it to the tool and in some cases its relative position to other tools should be considered. As an illustration of this last point, an open-type starting rheostat, if used, or unprotected magnetic control, should not be mounted on a machine in such a manner as to be exposed to danger of short-circuit by flying chips. It is now, however, only a matter of time before all live parts of both motor and control will be enclosed. In the majority of cases, a shunt motor of ½ h.p. and less would be started by a switch. Exceptions to this would be motors on tools that must be gotten under way slowly. With adjustable-speed motors care should be taken to first throw the switch on full field. Series motors up to 8 h.p. or even larger can be started by a switch without resistance. Exception to this would be cranes and tools requiring a certain amount of armature speed regulation. Larger motors for tools where starting service is infrequent or not severe, and for lineshafts, and for group drives, would be satisfactorily operated with a dial-type controller, which is cheaper than the drum controller, provided, however, that the controller is placed in a protected position.

When making installation, accessibility to the controller in case of accident should be kept in mind, even though but of little importance so far as starting up is concerned. The starting apparatus should be placed where the motor or some of the moving parts can be seen by the operator. On individually motor-driven tools, where the motor is started and stopped many times a day, or where the starting conditions are of a severe nature, or where tools are edged along, drum type controllers or magnetic control with extra heavy starting resistance should be used. For adjustable-speed motors using the drum type control, the field control should be connected through fingers making contact on segments of the controller drum and not by sliding contacts on a dial as with the latter trouble will develop sooner or later. With magnetic control, provision should be made in the control either to start the motor on full field or to provide necessary points for starting on weakened field in order to protect the motor. Motors of moderate size and larger, operating under severe duty cycles, are best controlled by magnetic switches. This class of starting apparatus will stand almost any amount of abuse and, by the addition of a simple current limit relay device, becomes practically a fool-proof protection for the motor. There are cases where it might be advantageous to use magnetic control even with smaller motors.

Squirrel cage rotor type motors, two-phase and three-phase, up to 5 or 8 h.p., generally speaking, can be thrown directly on the line, depending largely upon the power conditions. Above 5 or 8 h.p. this type should be operated by a com-

pensator or sliding resistance in the rotor, while for the slip-ring type a controller with external resistance should be used.

Convenient Arrangement of Control.

Upon the convenient arrangement of the control depends, to a considerable degree, the output of the tool; and the importance of the arrangement from the standpoint of the operator should not be ignored, since the output of a tool will be materially increased when an operator can start and stop the tool and obtain at all times maximum cutting speeds by simply turning a handle. The controller must be placed in a safe position and should be accessible for repairs, which very often mean that some arrangement is necessary to bring the operating handle within easy access of the operator. A familiar illustration of the convenience of control is the arrangement so commonly seen on lathes, whereby the operating handle travels with the tool carriage and allows the operator at all times a complete control of his tool. Strange as it may seem, this most important feature, the convenience of control which bears directly on production, is ignored in many tool equipments.

Power to Drive Tools.

Exhaustive tests have been and are being made to determine the amount of power required to drive tools. Hasty conclusions should not be drawn from incomplete data since they are apt to be misleading; for instance, where tests are made with motors which are considerably underloaded or overloaded, where efficiencies are not taken into consideration, where the material used and duration of test are not stated, or where there has been failure to state whether the test was a practical one or merely a breakdown test. The conclusions drawn from breakdown tests are often deceptive and should not be used for determining the power required to drive tools, for it does not follow that a tool which stands up longer than another under breakdown conditions will do the same under practical conditions. To develop a general formula that would be of practical value in determining the horse power required to drive tools would be difficult, as the power required varies with the metal worked, the cutting speed, the kind of tools used, the efficiency of the machine, and many other conditions.

The construction of the tool is seldom taken into consideration when estimating horse power, thus some of the worm-driven tools are notoriously inefficient. Other machines are so constructed that the greatest part of the power delivered to the tool is consumed in friction losses and not in useful work; again, the tool may be constructed upon approved lines but may not be stiff enough to stand the strains to which it is subjected thereby causing a considerable loss of power, all of which, as well as the difference in power due simply to the shape of a cutting tool, have been repeatedly proved by tests.

Again the duty required of a tool in one shop may be more severe than that in another, from which it will be seen that it cannot be accurately stated that a definite size of motor is required for a given tool. In the majority of cases, however, the horse power for small tools is very well fixed. With the larger tools the variation in horse power required for such tools, of course, is more pronounced and demand more consideration on account of the size of the motors involved.

Little trouble is experienced in obtaining new tools already arranged for attaching motors, since many of the tool manufacturers are alive to the superiority of the motor drive and have for years built tools especially adapted for motor drives. Unfortunately, others have seen fit to merely arrange a make-shift for attaching the motor, while still others leave the purchaser to attach the motor as best he can, and consequently the best results are not always obtained.

When the driving of old tools by individual motors is under consideration, the speed range, the number of similar tools to be equipped, and the condition of the tool should be taken into account. It sometimes happens that when a tool in itself would not call for an individual drive, certain circumstances might make such a drive advisable. As an illustration, when the majority of tools in a shop have become individually driven, there might still remain a number of scattered tools, which, unless they were driven by individual motors, would necessitate the running of long lines of shafting; or, in the event of moving into new quarters, a cement building perhaps, it is decided not to use line shafting.

Since production is the ultimate aim of progressive shop management, and since the electric motor is generally conceded to be the greatest factor in increasing production, it is only a matter of time before the motor will be universally used in machine shops.—G. E. Review.

TOOL-HARDENING ELECTRIC FURNACES.

A MODERN steel hardening furnace, in order to meet the requirements of the engineer of to-day should fulfil the following conditions, says Page's Weekly.

(1)—Rapidly reach and easily maintain constant the particular temperature required for any given class of steel.

(2)—Permit the practical recording of the exact temperature of the heated steel at any moment by means of a really efficient pyrometer attached to and forming part of the furnace itself.

(3)—Heat the steel or tool uniformly throughout and without overheating or burning any of its edges or projections.

(4)—Be capable of a gradual application of its heat so as to prevent sudden stresses and strains in the steel, which would probably cause the latter to warp and crack.

(5)—Not permit of the accidental contact of any foreign matter with the steel that is being heated, otherwise the carbon percentage of the steel may be altered or adversely affected.

(6)—Be placed in the immediate neighborhood of the cooling plant, so as to reduce to a minimum heat losses in the metal during its transmission from the furnace to the cooling liquid.

(7)—Only permit of the least possible amount of oxidation whilst in operation.

(8)—Not be dangerous to health; nor be liable to cause a fire or other damage to its surroundings.

(9)—Lastly, it should be simple and reasonably economical to operate, and must be efficient in the truest and broadest sense of the term.

The furnace consists essentially of an iron case, inside of which is a lining of firebrick, together with some suitable heat-insulating substance, and built into this lining is the crucible itself containing the metallic salt bath; then, fixed into and at each side of the crucible are the electrodes which transmit the electric current through the metallic salts, thus directly applying its great and uniform heating powers to all parts of the bath.

For regulating the heat, the furnace equipment includes a switch regulator, which varies the voltage. This regulating apparatus consists of an ordinary static electric transformer with the secondary winding connected to the electrodes in the bath, whilst the primary winding of the transformer, which is connected to the source of supply, is subdivided into a number of sections connected to the regulating switch contacts.

Peat Fuel.—Encouraging reports of the development of the peat fuel industry have been received from Alfred, Ont., where the Canadian Peat Co. is operating. This is the plant formerly operated by the Mines Branch of the Dominion Government. For several years a limited quantity of this fuel has been shipped into Ottawa, and has given the utmost satisfaction to all who have used it as a fuel for either kitchen ranges or open fireplaces. The company is now operating night and day and expect to have several thousand tons for delivery in Ottawa this season.

PRODUCTION METHODS AND DEVICES

A Department for the Interchange and Distribution of Shop and Office Data and Ideas Evolved from Actual Practical Application and Experience

TURRET LATHE AND VERTICAL BORING MILL PRACTICE.—IV.*

By Albert A. Dowd.

IN our August 13, issue, the first setting of the work in the sequence of operations covering the machining of a front hub for an automobile on the vertical turret lathe was dealt with. In the present instance the second setting and remaining operations to complete the work are detailed.

Second Setting of the Work.

Fig. 7 shows the method of holding and the necessary tooling for the second setting of the work. A cast iron fixture C is bolted to the face of the table by the three tee-bolts D, the tool steel plug E centering the fixture on the table. A driving pin B enters one of the flange holes (which are jig drilled between the first and second turret lathe operations). The upper end of the stud E is split in four places at K, is spring tempered, and ground at G to a diameter slightly smaller than the hole which it enters in the work. The lower portion F fits the bearing seat which has previously been machined. A hardened and ground tool steel operating plug is ground cylindrical at H and K and is threaded on the the lower end at L to a loosely fitting

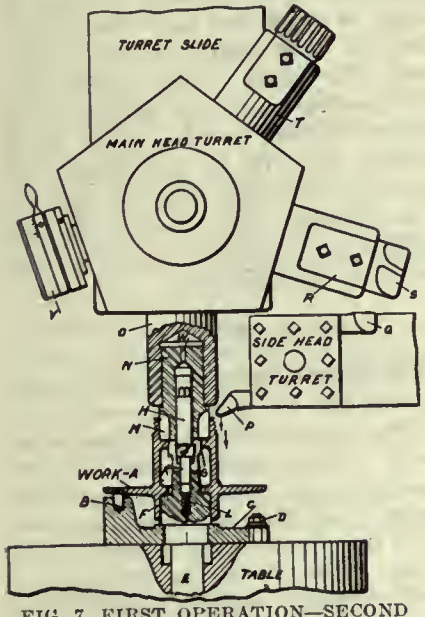

FIG. 7. FIRST OPERATION—SECOND SETTING.

thread. The fit at K is accurate so as to insure concentricity of the upper piloted end H, with the remainder of the fixture. The tapered portion is ground to fit the inside of the split end, and therefore serves to expand it as desired.

All internal cutting tools are furnished with a hardened and ground hole which acts as a guide for the stem H. In this setting of the work no boring tools are used, their place being taken by the four lip drills M and S. These drills are

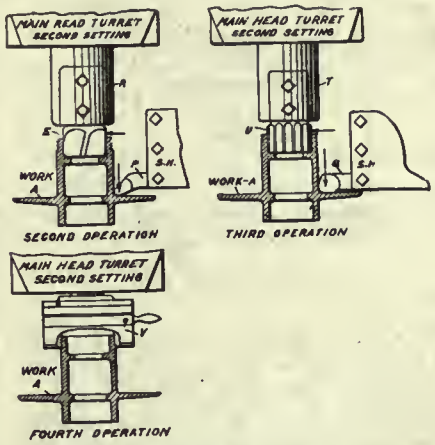

FIG. 8. REMAINING OPERATIONS—SECOND SETTING.

made of high speed steel and fit the holders O and R respectively. Air holes similar to that shown at W are provided in order to prevent air compression. A reamer U is held in the holder T and also pilots on the stem H. An opening die V is used to cut the thread on the outside of the hub. The tools P and Q in the side head turret are of high speed steel and are used for roughing and finishing.

Sequence of Operation—Second Setting.

First operation:—The tools shown in proximity to the work in Fig. 7 are used for the first operation, which is that of rough drilling out the bearing seat with the four-lip drill M in the main head turret, while the tool P in the side head faces the end of the hub, turns the thread diameter, and starts the turning of the outside of the hub. The four-lip drill should be turned in the holder so that the facing tool can pass in between the flutes.

Second operation:—The second operation is shown in Fig. 8 and consists of finishing out the bearing seat with another four-lip drill S similar to the one used in the first operation, but slightly larger in diameter, and being so proportioned as to leave about .012 for the reamer to take out While this tool is working the side head, tool P continues the turning on the outside of the hub until completed.

Third operation:—The reamer U shown in the third operation finishes out the bearing seat, while the finish turning and facing tool Q in the side head faces the end of the hub, turns the thread diameter and finishes the outside of the hub. A coarse feed is used for these operations, a sufficient "drag" being ground on the tool to smooth up the surface nicely.

Fourth operation:—The thread on the outside of the hub is cut by an opening die V, the operation of which is similar to that previously mentioned. This operation obviously completes the piece.

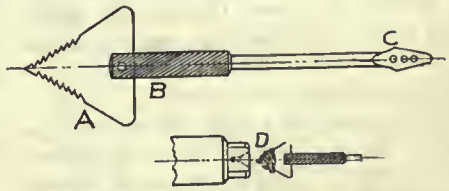
*Parts I. to III. of this series appeared in our July 30, August 6 and 13 issues.

COMBINED CENTRE HOLE CLEANER AND OILING PIN.

By James E. Cooley.

THERE is no regular means provided for cleaning out the centre holes in shafts, arbors, etc. A common method for doing this is to take a piece of waste, press it in the centre hole with the thumb, and twist it around several times. Another way is to fasten the waste on the point of a file shank or other similar tool and use this for a cleaner.

In the accompanying illustration is shown a combined centre hole cleaner and oiling pin. The cleaner A is a triangular piece of sheet metal, 1-16 in. thick, having a number of notches filed on the point, as shown. This is pinned through a slot on the end of the oiling pin B. On the point of the cleaner is tightly wound a piece of waste, as



COMBINED CENTRE HOLE CLEANER AND OILING PIN.

shown at D; this as seen is inserted in the centre hole, and when twisted around thoroughly cleans out the hole. The notches prevent the waste from slipping off the point.

The oiling pin is used for dropping oil in the centre holes before the work is placed on centres, and is kept in the oil well that is cast on the tail-stock of most lathes. The end is flattened and pointed similar to the one shown in the sketch. An idea shown in the oiling pin here is that of the holes at C, which are for the purpose of holding oil on the point. Usually it is necessary to dip the

pin in the well two or three times before sufficient oil is taken up to fill the centre holes. The holes, however, retain a sufficient amount at one dip. The end of the oiling pin is knurled for convenience in turning the cleaner around.

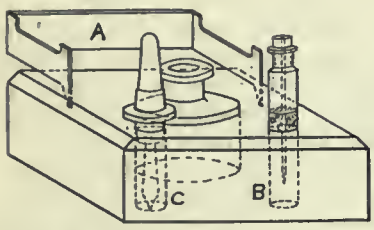
UTILIZING THE INK-BOTTLE HOLDER.

By James E. Cooley.

NEARLY every draftsman finds it necessary to use a holder for his drawing ink bottle, as the latter is easily tipped over. The holder is made from a square block of wood, having a hole bored out in the centre to hold the ink bottle, as seen in the sketch. As these holders take up considerable space on drawing tables, it is found that they can be utilized for other purposes than for just holding the drawing ink bottle.

The first of these to be noted is a pen and pencil-holder A made from a strip of sheet metal, bent in the shape as shown in the sketch and fastened in the block.

At B is a hole that contains a small bottle of oil, the oil being used for lubri-



UTILIZING THE INK BOTTLE HOLDER.

cating the adjusting screws and nuts on drawing instruments. Usually an oil can is kept in the drawing-room for this purpose, bnt as it is generally too greasy to handle, it is seen that the oil bottle is a needed improvement, and is neater besides. In the cork is fastened a toothpick for dipping out the oil.

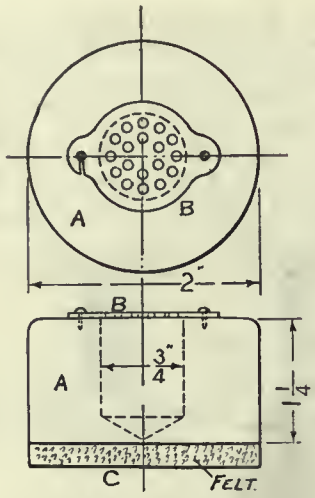
At C there is a hole containing the bottle stopper. When inking in figures on a drawing the pen has to be dipped freqnently in the bottle and the stopper is lifted out and put back each time, or it is left off, where it rolls around and smears the spot on which it is placed, the end or quill being covered with ink. If placed in the hole as suggested it cannot soil anything, and is out of the way.

TRACING CLOTH PAD.

By J. E. C.

THE glazed side of tracing cloth always requires to be rubbed down with pounce or chalk before it will take ink. This is usually accomplished by first sprinkling the powder from a can on the tracing cloth, and then rubbing this over the surface with a piece of waste.

In the accompanying sketch is shown a tracing cloth pad, which contains both the powder and the means for rubbing it over the tracing cloth. The pad is made



TRACING CLOTH PAD.

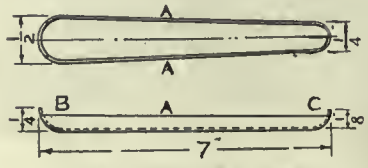
from a piece of round wood, as A, having a hole drilled in the centre to hold the powder. Over the hole is placed a movable tin cover, B, having a number of holes in it from which to sprinkle the powder. On the lower side of A is glued a round piece of felt, which is used for rubbing down the cloth.

SPOON FOR DRILL-CHIPS.

James E. Cooley.

A DRILLED hole that does not pass clear through a piece of work always contains chips in the bottom of the hole after the drill is drawn out, and it is necessary to empty them out. This is easily done by turning the work over. But on work that is fastened down or on heavy castings other means must be provided for removing chips from holes.

A very quick method for doing this is by means of the spoon shown in the ac-



SPOON FOR DRILL CHIPS.

companying sketch. It is made from a strip of sheet-steel about 1-16 in. thick. The two sides A, are first bent up, and then the ends B and C are rounded as shown. The spoon can be used for several sizes of holes, as it is tapered down for this purpose. The larger end B is used for cleaning holes above ½ in. diameter, and the smaller end C for holes of lesser diameter.

MODERN METHODS OF WORK

GEORGE BURMAN FOSTER, writing recently in the "American Artisan," on the advantages and disadvantages of modern methods of work, said: The machine has brought about a mighty revolution; labor becomes more and more mechanical; the individual himself works almost like a machine; such work makes a man one-sided; it dulls and deadens him. Everything creative is relegated to the machine, and the machine has gulped down personality; mechanism has triumphed. The modern method of work can very easily effect a depreciation of man as laborer.

Owing to the modern mode of labor, the articles necessary for our use and comfort can be produced in much shorter time. Combined with capitalism, the machine exploits the forces of nature in an undreamed-of manner; hence the possibility of shortening the hours of work. Hence too, the possibility of the laborer having more time for his family, for further development—in spiritual and technical ways, for finding nobler joys than his labor affords him. Machine work is in a position to give him means of culture for little money.

The modern mode of labor can restrict the disadvantages of mechanical labor also, so great is the quantity of production under present conditions of labor that want and misery can be fought much more effectively than formerly, and the conditions of our common human life have been actually improved under the influence of machine work. It shows as never before the value of "**team work**" and of combination. We belong to one another and are dependent upon one another. The division of labor has led to the union of labor. Each for all and all for each! Industries throw men together, but life in and through labor unions can, and probably is, a powerful school for the formation of character.

The Electric Furnace.—A new form of furnace, due to Ivan Rennerfelt, of Sweden, is provided with three electrodes. Two of these are mounted horizontally in the same plane above the charge. The third is vertical, and ends in the space between the horizontal electrodes. With three-wire two-phase or direct current, a compound arc is formed in the shape of a V and is projected down on to the metal. The electrodes themselves do not come in contact with the metal or the slag. The electrodes are contained in a cylindrical furnace which can be tilted, and the inner walls act as a reflector. Some of these can take about half a ton of iron at one charge.

Series of Practical Questions and Answers for Mechanics

Every care is being taken to include only pertinent practical questions, and give same direct, reliable answers. Catch questions will be avoided. Attention is drawn to the alternating course in arithmetic, a concurrent study of which is recommended with that of the Question and Answer Series.

PROBLEMS RELATING TO GEARS.

THE introduction of special machinery has largely done away with the necessity of gear calculations. This pertains mostly to the laying out of tooth forms. Problems in connection with diameters, pitches, etc., still often come to the average mechanic. The object of the particular shapes adopted for the teeth is to produce a smooth, continuous, true rolling motion between the wheels, and there are in use two general methods of producing these forms—namely, form milling and generating. The first requires a rotary cutter of the correct shape to plow out the space between two adjacent teeth, while in the latter a reciprocating tool is shaped and fed in such a way as to take the place of a rack tooth in mesh with the gear being cut. The result is a space that will accommodate the rack tooth throughout its whole passage through the gear.

In order to understand gear calculations, certain terms must be understood. Pitch diameter or diameter alone is the diameter of the gear if it were considered as a cylinder without teeth simply rolling against its mate without friction. The thickness of the tooth is its thickness measured along the pitch circle. The addendum is that portion of the tooth which extends outside of, and the root is that portion which is inside of the pitch circle. The surface of the tooth below the pitch circle is called the flank, and that above is called the face. Circular pitch is the distance from the centre of one tooth to the centre of the next measured along the pitch circle. Diametral pitch is the number of teeth of a gear for every inch of pitch diameter—that is, the total number of teeth divided by the pitch diameter in inches.

Question.—A pinion having 12 teeth meshes with a gear having 90 teeth. What is the ratio of pinion to gear?

Answer.—Ratio $= \frac{90}{12} = 7.5$, or, in other words, the pinion will make 7½ times as many revolutions as the gear.

* * *

Question.—A gear of 120 teeth drives one of 60 teeth, which is keyed to the same shaft as an 80-tooth gear. This, in turn, drives another of 48 teeth. What is the ratio of the gearing If the 120-toothed gear made 30 revolutions per minute, what would be the speed of the one with 48 teeth?

Answer.—Ratio of gearing

$$= \frac{120}{60} \times \frac{80}{48} = \frac{10}{3} = 3\,1/3.$$

$$\text{Speed of driven gear} = 30 \times \frac{10}{3} = 100 \text{ r.p.m.}$$

* * *

Question.—A driving shaft is fitted with a 36-tooth pinion. It is required to drive another shaft at one-sixth the speed, with available gears increasing by 4 from 24 to 72 teeth.

Answer.—Ratio = 6. To drive a shaft directly from the 36-tooth pinion would require a gear of 36×6=216 teeth, which is not available. Divide the ratio into 2, say 3 and 2. The first could be obtained by a combination of the 24 with gear of 24×3=72 teeth, while the second could be got by a number of combinations, say 32 and 64. The 24-toothed pinion would drive the 72-toothed gear, and the 32-toothed pinion fastened to the same shaft as the 72 would drive the 64-toothed gear. The ratio then is

$$\frac{72}{24} \times \frac{64}{32} = 6$$

* * *

Question.—What would be the circular pitch of a gear whose diametral pitch is 4?

Answer.—The diametral pitch multiplied by the circular pitch is always equal to 3.1416; therefore, circular pitch is

$$\frac{3.1416}{4} = .7854 \text{ in.}$$

* * *

Question.—A 6-pitch gear has 240 teeth. What is its pitch diameter?

Answer.—As the gear has 6 teeth for every inch of diameter, then diameter

$$= \frac{240}{6} = 40 \text{ inches.}$$

* * *

Question.—A 2-pitch gear is to be made with 36 teeth. What should be the diameter of the blank?

Answer.—Rule—Add 2 to the number of teeth and divide by the pitch, hence

$$\text{Outside diameter} = \frac{36+2}{2} = 19 \text{ inches.}$$

* * *

Question.—What is the circular pitch of a wheel having 240 teeth and a diameter of 60 inches?

Answer.—Circular pitch $= \frac{3.1416}{\text{Diametral pitch}}$

$$\text{Diametral pitch} = \frac{\text{Number of teeth}}{\text{diameter}}$$

$$= \frac{240}{60} = 4$$

$$\text{Circular pitch then} = \frac{3.1416}{4} = .7854$$

* * *

Question.—What is the distance between centres of two gears of 1 inch circular pitch and having 64 and 24 teeth respectively?

Answer.—Addendum = flank or working depth of tooth. Total depth of tooth = addendum plus flank plus clearance. Rule for distance between centres is: Multply working depth by one-half the total number of teeth in both gears.

$$\text{Working depth} = \frac{1}{\text{diametral pitch}}, \text{ and diametral pitch.}$$

$$= \frac{3.1416}{\text{Circular pitch}}. \text{ Working depth, therefore, is } \frac{\text{Circular pitch}}{3.1416}$$

$$= \frac{1}{3.1416} = .3183$$

Distance between centres is then

$$\frac{64+24}{2} \times .3183$$

$$= 44 \times .3183 = 14.005 \text{ inches.}$$

* * *

Question.—If the distance between centres of two gears is 24 inches and their speed ratio is 4 to 1, what would b the diameters of the two gears?

Answer.—Rule, for small gear diameter

$$= \frac{2 \times \text{distance between centres} + 1}{1 + \text{ratio}},$$

or diameter of small gear

$$= \frac{2 \times 24 \times 1}{1+4} = \frac{48}{5} = 9.6 \text{ inches.}$$

For large gear, diameter

$$= \frac{2 \times \text{centre distance} \times \text{ratio}}{1+\text{ratio}}$$

$$= \frac{2 \times 24 \times 4}{1+4} = \frac{192}{5} = 38.4 \text{ inches.}$$

NEW PROCESS DEVELOPMENTS

Inventive Genius and Research Operate to a Dual End — They Aim to Improve What We Now Possess and Bring to Our Service Commodities Before Unknown

QUALITIES OF CASE-HARDENING MATERIALS.

SOME particulars are to hand as to various qualities of case-hardening materials necessary for different kinds of work. It is claimed by W. H. Palfreyman & Co., of Liverpool, that hydro-carbonated bone-black is best suited to general classes of work; at the same time, where the uniformity of work is of no material value, a common bone-meal of the cheapest quality can be used.

When fancy mottled designs are required, which can be produced only by certain chemicals, hydro-carbonated bone-black cannot be used, but wherever the toughest, finest and deepest case is desired, or ordinary coloring only required, there is no material that will compare in either economy or quality with hydro-carbonated bone-black. The above firm have endeavored to generate all the desirable properties and avoid all those undesirable. In its manufacture, pure white bone, selected for its hardness is first taken, and all pith and grease removed. It is then ground to a uniform size or mesh, and placed in closed retorts, charred by a uniform slow heat, the temperature being uniform for every batch. As the bone comes from the hot retorts, all moisture is excluded, and it is immediately charged with rich carbon, extracted from a pure hydro-carbon oil. The pores are by this method filled with an oleaginous substance, which excludes all possibility of absorption of moisture, and guarantees more pure carbon to the pound or square inch than is possible to obtain in any other material.

By this process we are informed, three times the case-hardening power possessed by the ordinary forms of bone-black is guaranteed. This material can also be used for annealing.

COAL SMOKE ABATEMENT IN IRONWORKS

EARLY this year the British Local Government Board appointed a Departmental Committee to consider the question of coal smoke abatement, and on July 30, Professor J. W. Cobb, Livesey Professor in the Department of Coal, Gas and Fuel Industries (with Metallurgy) in the University of Leeds, gave evidence with regard to what has been done in this connection by the Farnley Iron Co., where he was for twenty years prior to going to Leeds. All the reheating of iron and steel for welding, hammering, or annealing is now carried out by the Farnley Iron Co., by means of gas-fired furnaces, with a considerable economy of material.

Gas Fired Puddling Furnaces.

The main advantage claimed for gas, of course, is its greater ease of regulation, coupled, at the same time, with the absence of smoke. Professor Cobb explained to the committee the difficulties of using gas in puddling furnaces. Puddling required the maintenance of a definitely reducing atmosphere for considerable periods of time unless excessive waste was to result, and this accounted for the evolution of considerable quantities of smoke from the furnaces. Experiments with gaseous fuel had not met with any large measure of success. The great difficulty was an economic one, since the use of gas was only possible with a regenerative furnace, in which a considerable proportion of the heat of combustion was restored to the gas and air which were to be burned in the furnace. Such a regenerative arrangement was always expensive to install, and such an expense in connection with a furnace which was only dealing with charges of from 350 to 550 lbs., was a very serious matter. This rendered the use of gas economically difficult. Furthermore, the conditions of work so far as the puddler was concerned were rendered worse by the neighborhood of large quantities of brickwork such as exist in regenerators. Even if a smokeless puddling furnace could be invented, it would be so much worse for the puddler that it would not be fair to adopt it.

Continuing, he said that even a gas-fired puddling furnace might make smoke. This was a very complicated question to explain, but what was known as smoke from gas fuel in ordinary work would also apply in large scale work. The formation of particles such as were obtained from coal could also be obtained from gas, but the advantages of the latter were that since it was possible to control the ratio of gas and air, it was easy to minimize the smoke formation to a very considerable extent, and there was not the same fluctuation as in a direct coal fire.

It was mentioned that the Farnley Iron Co. had not used gas for boiler firing yet. The average boiler, he said, was a very economical piece of apparatus, and there was not the same possibility of improvement in efficiency by the use of gas as there was in the other processes to which he had referred. On the whole, however, he was of opinion that there was need for further legislation to prevent the emission of smoke in industrial processes.

Technically Trained Inspectors.

A point of some interest which may be mentioned in connection with the evidence given by other steam boiler users is a general consensus of opinion that the present type of smoke inspector should be improved upon by the appointment of technical men, who would cooperate with the manufacturers with a view to making suggestions as to improvements in equipment. The feeling among many large steam users is that the local authorities treat them as hostile parties, and that they are more interested in the collection of fines than in the improvement of the atmosphere, and, consequently, in the public health.

AMERICAN PRACTICE IN ANNEALING STEEL CASTINGS.

THE following recommendations as to the annealing steel castings were recently issued by the American Society for testing materials:—

(1)—The castings should preferably be sufficiently cleaned of adhering sand before annealing to ensure thorough and uniform heating.

(2)—The castings should be heated slowly and uniformly to temperatures varying with the carbon content of the steel, approximately as follows:—

Carbon, per cent.	Deg. Cent.
Up to 0.16	925
0.16 to 0.34	875
0.35 to 0.54	850
0.55 to 0.79	830

Nothing in these recommendations shall operate against the temperatures aimed at being 50° and, in special cases, 100° C. higher than those given in the table, when necessary to attain the desired result.

(3)—The castings should be kept at the maximum temperature a sufficient length of time to ensure the refining of the grain. In general, the heavier the sections of the castings, the longer must be the time of exposure to the maximum temperature.

(4)—(a)—The castings should be cooled slowly and uniformly in the furnace, when it is desired that the steel shall possess the maximum softness.

(b)—The castings may be cooled at an accelerated rate, when it is desired that the steel possess rather higher tensile strength and elastic limit than can be procured by very slow cooling. This cooling must be so conducted as to leave the steel reasonably free from cooling stresses.

The manner of carrying out this accelerated cooling should be such as will attain the desired result. For instance, the castings may be withdrawn from the furnace and buried in a bed of material that is a poor conductor of heat, or the annealing furnace may be so thrown open that it will cool more rapidly than if left closed. Should the castings be of such uneven section that they cool at unequal rates at various points when the furnace is opened, especially if the carbon of the steel is high, the furnace should be closed after the castings have become black, and their further cooling so retarded that the stresses set up by the unequal rates of cooling are relieved.

STEEL IN IRON CASTINGS.

THE use of steel with iron in making castings must depend on the cost of the steel in the first instance, says W. J. May, in the Practical Engineer, London, Eng., because if this is much more than that of good hematite iron, very little is gained in return for increased cost where general work is concerned. For particular purposes exact cost does not always matter. Still, suitable steel for cupola work is limited in supply. A heavy demand would soon run up prices to a point that would make the use of semi-steel, or whatever the mixture be called, so much more costly than the best hematite castings that only for special purposes would the cost be justified. As an example of this increase in price, for some years I used scrap files and tool steel rather largely in a special manufacture and for the first two years from $20 to $22.50 per ton delivered at works was the price. Later, supplies dwindled and prices rose until at the end of the fifth year from $42.50 to $45 per ton had to be paid, and it was a trouble to get supplies even at these prices.

At the present time steel scrap suited for cupola work can be got at about $10 to $12.50 in the merchant's yard, which would make the price delivered run from $12.50 to $17.50 per ton, and as the price of hematite is about $16.50 plus carriage, this shows some slight advantage for the steel, as an iron costing about $13 per ton could be used with it, the total cost of the castings not being more than that of good hematite castings, while giving a greater strength probably. One point that tells in favor of the use of steel with iron in casting is that the metal is closer and cuts in the machine with a finer and better surface, while it can be brought to a fine polish where needed. The metal need not be unduly hard, and it will cut freely when properly melted. Like hematite, there will be a liability to hard skin surface on the castings with certain forms of moulding, and for this reason pickling should be adopted wherever possible.

Objection to Steel in Cupola

Generally, the objection made to the use of steel in the cupola is that it requires a greater heat than grey iron to make it fluid, and that the blast pressure has to be so high that the metal is whitened and rendered hard; but this is rather a mistake. To melt steel no greater air pressure is required than for iron. A small increase in the coke may be necessary, while, to obtain quicker and more intense combustion with greater heat, an increased volume of air may be needed, but certainly where the pressure is sufficient for iron it is sufficient for steel melting. Not only foundrymen but others connected with mechanical trades overlook the fact that carbon must have a certain amount of oxygen supplied to reduce it to carbonic acid, and given this supply of oxygen at a pressure enabling it to reach all parts of the fuel, there is no advantage in increasing the pressure. At the same time, if the air volume be increased, the fuel will burn more quickly and the total heat be corespondingly increased, while on account of the quicker working when confined within reasonable limits, more refractory material can be melted. Usually where the air propeller and carrying pipes are large enough and there is no choking of the blast by enlarging the tuyeres a large increase of heat is secured combined with quicker melting, the pressure remaining the same, while the content of the metal is not materially changed.

Both the tensile and transverse strength of the iron is increased by the addition of steel, and according to the kind of iron user, scrap steel may be added up to about 40 per cent. of the total charge, although usually a smaller percentage would be sufficient. It is not desirable to use steel with common mixed cast iron scrap, however. Generally, the castings come out well and very sound, few wasters being produced. There is often rather more contraction than with iron alone, and this has to be allowed for. Otherwise the use of steel with grey iron for castings is an advantage when properly arranged.

FERRO-MANGANESE STEEL ALLOYS.

DEALING with the question of electrically melted-ferro-manganese, a recent issue of Metallurgical and Chemical Engineering states that although the use of molten instead of solid ferro-manganese in steel manufacture results in a very considerable saving of alloy, and by making the deoxidation more efficient gives a better steel, the trouble and cost of melting it and keeping it molten has generally been considered as greater than the advantages obtained; but now electric furnaces are coming into wide use for the purpose, and are giving highly satisfactory results.

In America the first firm to take up this practice has been the Illinois Steel Company, who have installed a 4-ton Hercult furnace to keep on hand a supply of molten ferro-manganese, from which 150 lbs. are taken every seven minutes. They have found that besides the saving in alloy there is a clear advantage in quality.

The results from a 3-ton 350 k.w. ferro-manganese melting furnace, of the three-phase, 50 frequency, three-ring Roechling - Rodenhauser type, from which some 30 to 50 tappings, ranging each from 198 lbs. to 264 lbs., are made every 24 hours, depending upon the demands of the steel plant, are of interest. For the first five weeks the average energy consumption, excluding the energy required for burning in the lining, was 721 k.w. hours per ton for an output of 220 tons of ferro-manganese. To maintain the furnace hot, during long intervals 200 k.w. to 250 k.w. are required.

As a result of using molten ferro-manganese, an average saving of 30 to 40 per cent. by weight of ferro-manganese required is recorded. With cold ferro-manganese from 15 lb. to 18 lb. are used per ton of steel, and during a year some 2,100 tons of cold ferro-manganese are required. With molten ferro-manganese this amount is reduced to less than 1,400 tons, representing a saving of more than 700 tons, which at £11 per ton represents a saving of £7,700 per year. For burning in the lining and heating up a 3-ton furnace about 3,500 k.w. hours are required, and a life of about 84 days of 24 hours may be expected from the lining. These results, however, only apply to induction furnaces.

Hardening Dies and Punches.—When hardening dies and punches, in which there are screw and dowel pin holes, it is common practice to plug the holes with asbestos, of the wick or granulated form. Where this is done, trouble is often experienced in cleaning out the holes, as the asbestos sometimes becomes baked on. To avoid this trouble, the asbestos should be mixed with graphite and oil, as holes plugged with this mixture can be readily cleaned and will be found entirely free from scale and the like.

PROGRESS IN NEW EQUIPMENT

A Record of New and Improved Machinery and Accessories for the Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

VERTICAL DUPLEX PISTON PUMP

THE cut herewith illustrates a vertical duplex piston pump, manufactured by the Smart-Turner Machine Co., Hamilton, Ont. These pumps, being vertical, take up less space in the engine room and do away with the tendency—which is present in horizontal pumps—to wear on the bottom side of the steam and water cylinders. This has a direct effect upon the life of the plunger.

It will be seen that the suction and discharge valves are so placed that they are readily accessible, and that it is not necessary to open up the whole of the valve chamber to examine or repair any particular valve. These pumps are suitable for either stationary or marine service.

VERTICAL DUPLEX PISTON PUMP.

MACHINE TOOL EXHIBIT.

THE Canadian Fairbanks-Morse Co. have arranged a permanent exhibit of machine tools in their warehouse on Front Street, Toronto, which consists of, among others, the undernoted individual units. Our illustration shows a corner of the layout.

A Brown & Sharpe No. 2 plain milling machine, which embodies in its construction the latest improvements. There is to be noted the feature common to all Brown & Sharpe milling machines of an unsplined table screw, following out the best modern practice in engineering design, also the location of the train of back gears between the cone and the front spindle box, thereby obviating any tendency to chatter on heavy cuts. The single lever for clamping the over-hanging arm and the clamping of the knee from the front of the machine are also shown. There are also embodied the latest refinements of feeding mechanism with "**foolproof**" features.

A Stockbridge 18 in. two-piece crank, single pulley drive shaper. This, we understand, is the only shaper on the market fitted with a two-piece crank mechanism, which gives a uniform cutting stroke and a 3:1 quick return. The type of knee support is also claimed to be new and exclusive to this shaper; the box table having on the front rail a sliding support equal to its own width, making the knee practically solid. The machine is fitted throughout with taper gibs, while the bearing for the ram is fitted with planer type oil rolls. Speeds are selective and are operated through a friction clutch; there being eight changes of speed with a variation of 8 to 100 strokes per minute.

A Seneca Falls 14 in. x 6 ft. geared head toolroom lathe. This lathe is fitted with all-geared head, self-lubricating through pump contained within the head, giving eight changes of speed with three levers and variation of 9 to 456 r.p.m. A compact form of quick change feeding mechanism is fitted, this being controlled from the apron and fitted with automatic tripping device with micrometer adjustment. A special feature of this lathe is the micrometer stop on the cross-feed, which enables the tool to be set for either inside or outside cutting. This stop is of entirely new design and enables a reading to be made directly in thousandths in the regular way, or in two-tenths of a thousand per graduation of the thimble to the left. As this positive stop is contained within the body of the cross-slide hand wheel, there is consequently no straining of the crossfeed screw when striking the stop and, therefore, an accurate reading in every instance.

A Pratt & Whitney 16 in. x 8 ft. engine lathe, cone drive, and fitted with quick change gears, apron control, taper attachment, compound elevating rest and quick withdrawing attachment to the cross-slide, with full set of collets and chucks.

A Barnes 24 in. all-geared manufacturing drill fitted with back gears and oil pump and piping. This machine gives eight speeds varying from 25 to 248 r.p.m.. all obtained through a series of gears and controlled by three levers. It is to be noted that there are no right angle drives in this machine, 45 deg. being the greatest included angle, enabling very coarse pitch gears to be used in the bevel drives. Eight changes of feed are pro-

CORNER OF CANADIAN FAIRBANKS-MORSE CO., TORONTO, MACHINE TOOL EXHIBIT.

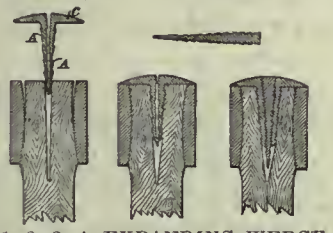
vided in two series, ranging from .004 to .075 in. per revolution of spindle. Ball thrust is fitted to the spindle, with automatic knockout and quick return; all gears being efficiently guarded. The oil pump and tank are self-contained, being fitted with relief valve to avoid back pressure.

A Sibley 24 in. drill with cone drive, power feed and plain table, which is a sturdy belt-driven tool, but differing in every way to the one previously described.

A Henry & Wright 8 in. over-hang high speed sensitive drill. This tool is fitted with ball bearings throughout and arranged with four speeds, all controlled from the front of the machine, altogether a high class tool and embodying all the modifications and improvements found necessary by the builders in their extended experience in high speed drills. This machine will efficiently drive drills from ¾ in. to ⅛ in., the combination of sliding head and sliding table giving an exceptionally wide range.

EXPANDING WEDGE FOR HAMMER HEADS, ETC.

NOT the least of the many little annoyances the mechanic meets with in the course of his work is the loosening of hammer-heads from their handles owing to the shrinkage of the wood. This is of frequent occurrence in spite of the rather makeshift methods usually adopted to prevent it, and is often the cause of rather serious accidents. Attention is therefore called to a patented expanding wedge for the purpose of fixing the heads of hammers, axes, picks, and other



FIGS. 1, 2, 3, 4. EXPANDING WEDGE FOR HAMMER HEADS, ETC.

similar tools. The inventor claims that the heads are thereby fixed with absolute security, so that the time wasted in tightening them up while work is in progress is saved, and the possibility of accidents arising from the heads flying off and injuring persons or property is eliminated.

The accompanying illustration, which is more or less self-explanatory, shows the design of the wedge and the method of applying it to fix a hammer-head. The device will be seen to consist of a pair of tapered side-plates lettered A in Fig. 1, pinned together at their thin ends for convenience in fixing, and a central wedge, Fig. 2, the object of which is to expand the side plates. The inner and outer faces of the side plates, and the two faces of the wedge, are serrated, as shown, so that slipping of any part is prevented.

To apply the device, a saw cut a little deeper than the thickness of the head is first made in the end of the handle, as shown in Fig. 1. The head having been placed in position on the handle, the side plates are driven into the saw cut so that the projecting flanges are flush with the end of the handle and the head, as shown in Fig. 3. The central wedge is then driven in between the side plates into the position shown in Fig. 4. This operation bursts or shears the pin connection between the side plates, and forces them apart, so that the wood is expanded sufficiently to fill the hole in the head completely; the latter is therefore quite immovable. If, after a time, any further shrinkage of the wood should occur, it can be taken up very easily by driving the central wedge down another notch, and this operation can be repeated several times if necessary. In this way the wedge might be driven half-way through the head, though the amount of shrinkage thus taken up would be greater than is ever likely to occur in practice.

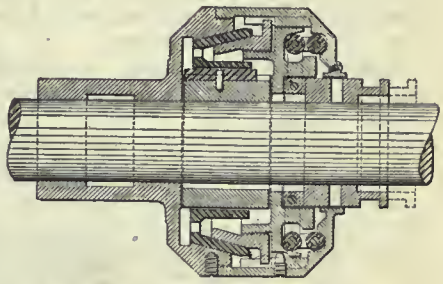
These wedges are made by the Patent Expanding Wedge Co., 114 Great Portland street, London, W., in fourteen different sizes, of which the smallest measures 15-32 in. by ⅞ in., and is suitable for a head weighing ½ lb.; the largest size measures 1⅜ in. by 2½ in., and can be used for heads up to 14 lbs. in weight. They are very inexpensive, and their use would often save the cost of fitting new handles.

MULTIPLE DISC CONE CLUTCH.

THE Ideal Multi-Cone Clutch built by the Akron Gear & Engineering Co., Akron, Ohio, is a decided departure from the usual type of friction clutches. The ideal multi-cone clutch has retained the simplicity of the two-cone clutch, greatly increased the pulling power in less space, allows smooth engagement due to momentary slippage, and will, it is claimed, release instantly. The small diameter and consequent light weight permit high speed and location on line shafts.

To avoid too sudden engagement of the cones, their face angles are greater than those of the ordinary two-cone clutch, and the clutching force and pulling power so lost is more than compensated for by the addition of a third cone, which really doubles the pulling power. The cones running constantly in oil have oil films between them, and these films permit a slippage before being broken down by the pressure of the cones coming into engagement. Proper face angles of the cones, and small unit pressure on same, as well as the oil bath, permit immediate disengagement when clutch is thrown out. The third cone doubles the total area of the friction surfaces, which reduces the unit pressure thereon, and gives them longer life. The clutch throws in with extremely small force and little movement of shifter sleeve, making it very suitable for foot control or places where long levers are prohibitive.

There are no projecting parts to catch workmen. The outside is smooth and



MULTIPLE DISC CONE CLUTCH.

all working parts are completely enclosed in a cylindrical oil-tight and dust-proof casing. No outside part of clutch revolves when clutch is out, if mounted as shown in illustration. The adjustment is made very quickly by turning shifter sleeve, and this may be done with shaft running, if mounted as shown. It is not necessary to shut down an entire line of machines to adjust one clutch.

The horizontal pressure exerted by the throw-in mechanism is distributed equally around the complete circumference, and cannot distort the cones from a true circle. When the clutch is out, the throw-in mechanism is still, and centrifugal force cannot throw it in. With clutch in, centrifugal force cannot throw it out, but instead will tend rather to keep it in. The clutch is easily put in place while self-contained, without altering the adjustment made in the maker's shop, and the casing can be easily removed and slid along the shaft, exposing all inner parts for inspection.

RECORDING LIQUID METER APPLICATION.

IT is universally conceded that the fuel bill represents by far the largest expense in the operation of a power plant, manufacturing or otherwise. Of the heat units available from the 200,000,000 tons of coal burned each year under power plant boilers in the United States, it is estimated that almost fifty per cent. is wasted from one cause or another. Since the marketable supply of coal is steadily increasing in price, power plant and factory owners are awakening to a more thorough consideration of the fuel bills,

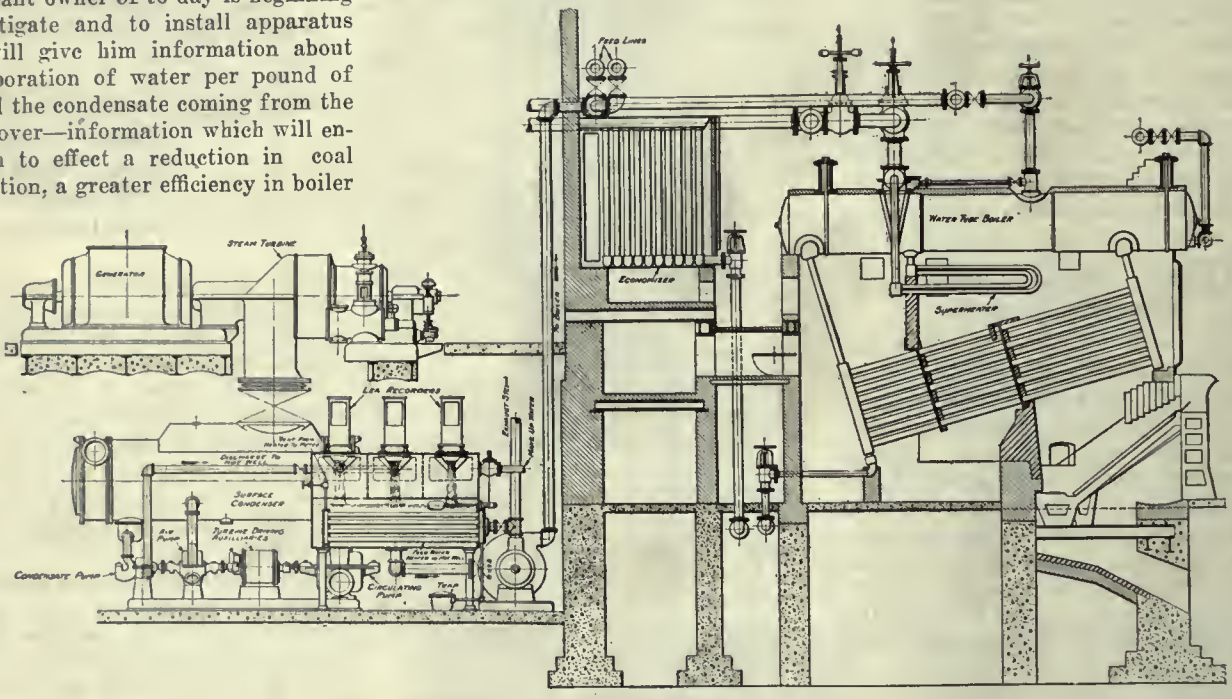
and to apparatus designed to give information leading toward their reduction.

Until quite recently power plant measurements have been confined chiefly to the last and most efficient step in the transformation of heat units into horse-power, few plants of any size being unequipped with volt-meters, ammeters, steam engine indicators, etc. This, it would seem, however, is working upon somewhat the same principle as locking the door after the horse is stolen, since the greatest losses in economy occur long before the arrival of steam at the prime mover, the transformation of mechanical power into electricity, or indicated horse-power into shaft horse-power.

The plant owner of to-day is beginning to investigate and to install apparatus which will give him information about the evaporation of water per pound of coal, and the condensate coming from the prime mover—information which will enable him to effect a reduction in coal consumption, a greater efficiency in boiler operation, a more economical production and use of steam. These determinations all involve water measurements, in most cases hot water, since engineers are universally agreed that economy and good management demand the feeding of water to the boiler at a temperature above 160 degrees.

Water heated by exhaust steam or by flue gases effects a very considerable saving in fuel, since heat imparted to the water in feed water heaters, or in fuel economizers, takes the place of an equivalent amount of heat that otherwise would have to be supplied from fuel on the grates. With a reliable and efficient means for keeping a continuous record of the consumption of boiler feed, condenser returns and make-up water, the owner or operator is enabled to determine many facts tending towards economy in that part of the plant where the greatest wastes generally occur. In this connection, the application of what is claimed to be an entirely successful recording liquid meter to a modern steam power plant equipped with fuel economizers and feeding water little below the boiling point, will be of interest to manufacturers, power plant owners and operators.

The accompanying drawing shows a boiler room containing standard type water tube boilers equipped with superheaters; the products of combustion discharging through economizers on the way to the stack. The engine room shown is equipped with horizontal turbine-driven generators using a typical surface condenser with turbine-driven air pump, condensate and circulating pumps. It is also equipped with a centrifugal turbine-driven boiler feed pump, which discharges into the economizers, the pump taking its feed water from the combined Lea V-notch meter, heater and hot well.



"LEA" RECORDING LIQUID METER APPLICATION.

The combination of boiler feed meter, heater and hot well shown on this drawing is of particular interest, because of the application of the Lea V-notch meter to the measurement of the various elements going to make up the total boiler feed water. The drawing shows three V-notch meters built in and forming part of the hot well of the plant. The meter on the left receives the condensate from the turbine shown on the drawing and measures accurately the steam consumption of the generating set. The meter in the middle receives the condensate from turbine and surface condenser No. 2, while the third meter on the right is used for the measurement and control of the necessary make-up water. These three elements go to make up the total boiler feed water.

On the extreme right of the tank is shown a balanced control valve connected with the make-up water line. This valve is operated by means of a float and lever from the water level in the hot well below the meters, so that if there is not sufficient condensate coming back from the surface condensers to feed the boilers the water level in the hot well drops and in turn opens the make-up water valve. The feed pump draws its supply directly from the bottom of the hot well.

As it is desirable to have the feed water enter the economizers at an approximate temperature of 150 to 160 degrees in order to prevent sweating of the economizer tubes, and as the condensate leaves the condensers, under the best of conditions, at between 80 and 90 degrees F., and as the make-up water enters the hot well at a considerably lower temperature (usually dependent upon the outside or atmospheric temperature), it becomes necessary to introduce a heating element to raise the temperature of the boiler feed to the proper entering temperature for the economizers.

This condition has been met in the plant by introducing in the hot well of the meter a tubular heater, which receives exhaust steam from the boiler feed pump, or some other auxiliary. It will be noticed that this combination of meters, hot well and heater economizes floor space and gives a method of control of the elements entering into the boiler feed, both as to quantity and temperature, that is of great value to steam power plants using fuel economizers.

From the foregoing it would seem that the method outlined above, should produce very satisfactory results in steam plants equipped as described.

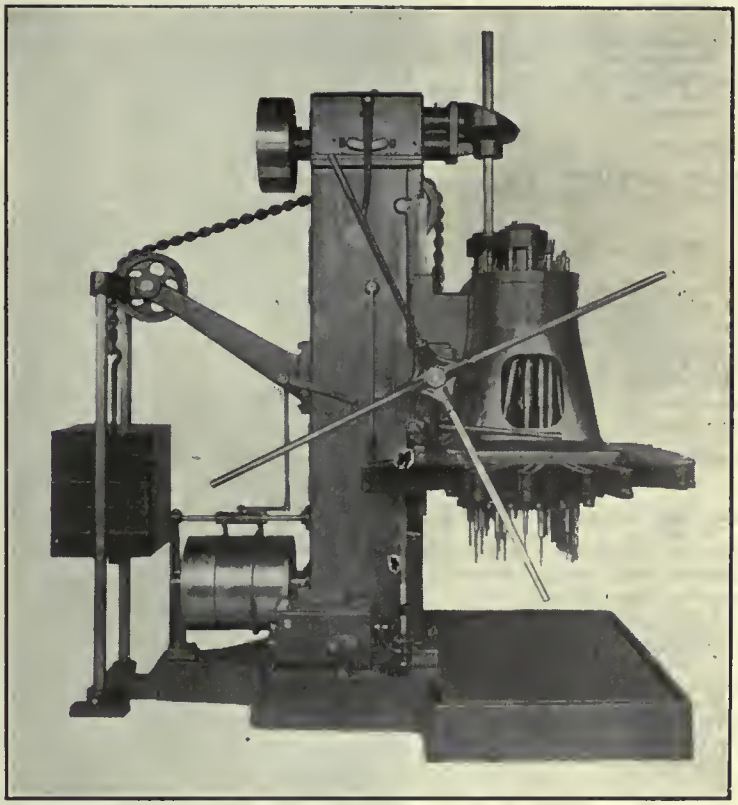
MULTIPLE SPINDLE DRILL.

THE National Automatic Tool Co., Richmond, Ind., has just added to its already complete line of multiple spindle drills the No. 30 machine, illustrated herewith. This is a large, heavy machine, built to meet the demand for a multiple drill capable of carrying a large number of adjustable spindles over a large drilling area. A machine of this type is particularly adapted to such drilling as automobile crank cases and any work of similar nature. The machine illustrated is capable of carrying from 3 to 44 adjustable spindles, or it may be equipped with cluster boxes carrying from 3 to 90 spindles. The size of heads furnished on this machine are 16 x 30 ins. and 16 x 44 ins. The machine shown carries the latter head, and was furnished to a motor manufacturer for drilling six cylinder crank cases in one operation. It is built along simple and sturdy lines, and has ample power to drive high-speed drills to their maximum efficiency, regardless of speed.

A single pulley drive is employed, so that the machine may be belted direct to the line shaft if so desired, or if individual motor drive is wanted it is also easy to apply this. The driving pulleys are of large diameter and wide face, and are mounted on Hyatt roller bearings. The speed box is located at the top of the column, and three changes of speeds are provided by the sliding gear transmission. The gears are of coarse pitch and wide face, and are hardened and ground. For each speed obtained from the speed box there are two independent changes of speeds in the head made by the means of the sliding gearing in the head. These changes are made while the machine is running. The bearings in the speed box are also provided with Hyatt high duty roller bearings, which insure a high transmission efficiency. The speed box and feed box gears are provided with the Cascade system of lubrication.

There are three independent drill feeds which permit the use of any feed with either of the three double drill speeds that are available in the head. All of the feed changes can be made while the machine is running. The feed box is located at the base of the column, the feed gears being cut from the solid, hardened and ground. They are of large diameter, and run at moderate speeds. The cover of the feed box is provided with a small tray, convenient for holding tools. The machine is mounted on a heavy base, which is provided with an oil channel for catching the overflow. This channel has a screen pocket, through which the cutting lubricant must flow to enter the tank from which it is pumped back to the tools. The pumps employed for oiling the machine and delivering cutting lubricant to the drills are independent of each other. When so desired, the base of the machine may be provided with T slots.

Any head furnished on this machine may be equipped with various combinations of adjustable spindles and cluster boxes for drills ranging in size from ⅛ in. to 1 in. in diameter. The head is provided with power feed and with a pilot arm to facilitate advancing and returning easily and rapidly. The power feed may be tripped either automatically or by hand, while the head is counterbalanced by means of three chains which support a counterweight within the column, and also additional sectional counterweighting in the rear of the machine to compensate for the variations in the number of arms used.



NATIONAL ACME NO. 30 MULTI-SPINDLE DRILL.

The column is heavy and rigid and of box section. The spindles are made of special steel hardened and ground, and are provided with ball thrust bearings at the lower end and lock nuts at the upper end to take up any end wear that may develop. The spindles are made to carry either straight shank or Morse taper shank drills as required. Individual flexible oil tubes deliver the cutting lubricant to each drill when the machine is working on steel or aluminum. The bronze bearings which carry the drill spindles are provided with a vertical adjustment to compensate for the variation in drill lengths. This adjustment is easily and quickly secured by simply loosening one nut, which is always accessible, regardless of how close the spindles may be clustered together. When vertical adjustment is needed, it is not necessary to move any arm from its set position. This spindle adjustment is a patented construction and holds the bearing rigidly to the end of the arm, while the arm may be moved to cover any layout within the range of the head. The universal joint used on all Natco drills is milled from the solid and carefully hardened. It is composed of only five pieces, and does not depend upon pins that may be broken or upon screws that may work loose. The universal joints are guaranteed for two years.

One of the most important features of this machine, which is used exclusively on Natco drills, is the independent drill speeds in head, which give two independent changes of speeds to each spindle for each of the three changes of speeds obtained in the gear box. This enables large and small holes to be drilled simultaneously at correct cutting speeds, it being a recognized fact that it is impractical to drive drills of different sizes at the same speed or feed per revolution.

The Herbert Morris Crane & Hoist Co., Toronto, have received an order from the Board of Education of the city of Toronto for four telescopic ash hoists which will be installed in four of the schools coming under the jurisdiction of the Board.

THE WAR AND BUSINESS.

IT is quite apparent that the European War as far as it has progressed has been fraught with disastrous results, not only to commerce and industry in the countries more immediately involved, but in every land where business enterprise has a foothold. That some degree check or upset should result was only natural because, in spite of fads and creeds, we are nationally, Imperially or internationally, as well as individually, interdependent. However, this may be, we need not lose sight of the stern fact that as individually we can be done without, so in the business or trade reciprocity sense we as a nation can both do and be done without.

The loss of trade brought about through the war, with our enemies, our allies or with neutrals, is no reason why Canadian industrial enterprise should suffer impairment or why our business interests should court despair and invite inactivity. Our industrial position and agricultural prospects were, it is true, not in the most stable shape for some considerable time previous to the war, yet no reasonable deduction can be drawn even from such circumstances as to warrant the **stage fright** attitude adopted these last few weeks. Too much attention by too many of our people —those who direct and those who serve included, has been given to the war campaign plan and progress,

We are in such hearty accord with the Motherland, with her allies and with the cause, that we believe it to be only effective if we devote ourselves, heart and soul to its expression and propagation. No greater misconception of duty is to be comprehended—the duty to our own kith and kin who are doing the grim work, and duty to ourselves as citizens of Canada. With commendable expedition a number of schemes have been launched which have the threefold purpose of providing men for the firing line fully equipped, of succouring the wounded, and of ensuring sustenance and comfort to the families whose bread-winners have gone. We want to be careful, however, that the base from which our supplies are drawn does not become isolated from these purposes through unwarrantable business inactivity and pessimism. We have now got well over the shock which the declaration of a wholesale European War created, and even so soon are able to forego the questionable luxury of unreliable and panic-fostering news—happily confined to a very small section of the Canadian press.

The temporary disorganization of our business, it being only such, as heads are getting level again, was traceable to no other cause than that of a few newspapers running amuck, but that such a condition of affairs should be allowed to prevail is evidence that the Press Association Executives are powerless to discipline. Until some such powers as are vested in the legal, medical and other bodies, become a constituent part of our Press Associations, just as surely will people's attention be diverted from their daily work and callings when scare head lines invite parting with a brown cent.

At this writing, the industrial outlook has brightened considerably since a week ago, our big corporations and those responsible for extensively equipped business enterprises having in the interval **set their houses in order** and made plans to not only maintain employment at the maximum possible, but to aggressively prosecute a campaign whose new business results will largely augment that employment. It has been realized that our workpeople will give expression to their loyalty and give of their substance to the various humane organizations more readily when opportunity to earn is their portion, while at the same time those who make employment provision, play an equal, if not greater part.

In a period such as we have been passing through, there is always a possibility that the small employer or dealer suffers unduly, and that generally unwittingly. By this we mean that our larger business concerns are apt to overlook him in settling with reasonable promptness, numerous, and it may be comparatively small accounts for goods supplied. It is too often assumed that the business man in a small way can be side-tracked temporarily in the interests of shareholders and employees. Such a proceeding is rarely, if ever, justifiable and, while the interests of our plant shareholders and employees are being safeguarded to the utmost, let us not forget the small employer and trader who also fills a not inconsiderable place in our business economy.

INDUSTRIAL NOTABILITIES--No. 49

WILLIAM PEARSON GUNDY, vice-president and general manager W. J. Gage & Co., publishers and manufacturing stationers, Toronto; vice-president and managing director Kinleith Paper Co., St. Catharines; vice-president Educational Book Co. of Toronto, Ltd.; president Toronto Board of Trade, 1914, was born at St. Catharines, Ont., Nov. 7, 1858, the son of Rev. S. B. and Susan (Pearson) Gundy; paternal ancestors were Irish, maternal, Canadian.

He was educated at the Model School, Toronto, and when fifteen years of age entered the Civil Service in the Queen's Printer Department of the Ontario Government where he remained several years.

Mr. Gundy began his business career in 1881 with W. J. Gage & Co., opening a branch house for that firm one year later in Winnipeg, and returning in 1884 to Toronto,

WILLIAM PEARSON GUNDY

afterwards assuming the management of the Gage business in 1890. He became managing director in 1893, and was made vice-president and general manager in 1912.

He was a delegate to Congress of Chambers of Commerce of the Empire, Montreal, 1903; was chairman Toronto delegation to Congress of Chambers of Commerce of the Empire, Guild Hall, London, 1912; is trustee National Sanitarium Association; trustee Toronto Free Hospital for Consumptives; trustee Toronto General Burying Grounds Trust; governor Toronto Conservatory of Music, and trustee Metropolitan Methodist Church, Toronto.

Mr. Gundy married May Richardson Simpson, daughter of Henry Simpson, Barrie, Ont., October 6, 1886.

His clubs are the York, National (president 1913-1914), Lambton Golf and Rosedale Golf, while his recreations are golf, hunting and fishing. His residence is 4 Hawthorn Gardens, Rosedale, Toronto, Ont.—Photo, courtesy International Press.

Specific Industrial Opportunities for Manufacturers

By a Staff Reporter

No individual, however generally superior in the eyes of his fellows, has a monopoly of gifts or is a perfection in personality, and we esteem it well that it is so. In like manner no one location in our Dominion has a monopoly in the matter of attracting industries. With the almost endless variety of the latter there is fortunately an equivalent personal condition existent; manufacturers have therefore a wide choice and can shrewdly estimate the value to themselves of the different facilities offered.

SARNIA, ONT.

"SARNIA lights the way" industrially and also as a port of considerable note. The town was incorporated in 1857, and this year received a city charter. The population is about 12,000, with assessment valued at approximately $6,500,000. The city is at the gateway to the Upper Lakes, being at the junction of the St. Clair River and Lake Huron, thus placing it on the highway between Lakes Erie and Huron, through which a large amount of shipping passes yearly. The well-known steamers of the Northern Navigation Co., now the Canada Steamship Lines, Ltd., ply from Sarnia, while a large number of freighters also make it a port of call.

Its location has to a very great extent been responsible for the industrial growth which has been so pronounced in recent years. Manufacturers in Sarnia have easy access to the Western markets and have a further advantage of a water route and low freight rates, while rail connection with East and West is made by means of the Grand Trunk Railway. That remarkable engineering work, the St. Clair Tunnel, is near Sarnia, and on the main line to Chicago, Ill. Ferries run regularly during the navigation season to Port Huron across the river, connecting with the Pere Marquette Railway.

The most important industry in Sarnia is that of the Imperial Oil Co., who have an immense plant at the southern end of the city, to which oil is piped from a point 90 miles distant, in the United States. The H. Mueller Mfg. Co., of Decatur, Ill., has established a modern plant here for making brass goods and plumbing supplies, the present plant being the nucleus of what will yet be a large industry. The Cleveland-Sarnia Saw Mills Co. has a large factory here, while a number of smaller concerns have also established industries in the city.

From a shipping standpoint, the Reid Wrecking Co., of Sarnia, has rendered invaluable service on the Great Lakes in salving wrecks. They are reputed to have the best wrecking outfit on the Upper Lakes and judging by the results obtained, especially since the severe storm last November, this reputation is justified.

Sarnia owns the water works and has just completed an extensive pumping and filtration plant. The city is a delightful place in which to live, especially in summer, when full benefit can be obtained from the extensive water front. An active Board of Trade under the presidency of Oscar Mueller is enthusing new life into the city and important developments will no doubt be seen during the next few years.

PRINCE RUPERT, B.C.

THE opening of through traffic on the line of the Grand Trunk Pacific Railway this Fall will undoubtedly be followed at Prince Rupert—the Pacific terminal—by the establishment of many new industries, in which the natural resources of the country will play a prominent part. Prince Rupert will undoubtedly secure the great fishing trade that is now being developed in the waters of the North Pacific. Fish curing and packing plants are being projected, and one of the most modern cold storage plants, representing an expenditure of over one million dollars, has been in successful operation for some time. Scattered along the coast line at stragetic points and on the Skeena and Naas River, are a score of salmon canning establishments, while at Naden Harbour, at the north end of the Queen Charlotte Islands, is located a whaling station. The products of these different industries of the sea will eventually be handled through Prince Rupert for distribution to the four corners of the globe.

Mining Industry.

The development of the mining industry is another important factor that will add to the upbuilding of the city and in the very near future the needs of reduction works must be provided. Within a radius of 200 miles are to be found some of the largest deposits of minerals on the continent and with the exception of the Granby camp, all ores at present have to be sent long distances for treatment. This additional expense for transportation mitigates against the development of many low grade mines whose ore contents cannot stand the cost. A smelting plant, treating both copper-gold and silver-lead ores, located at Prince Rupert, would command the output of the Portland Canal, Queen Charlotte Islands, Alice Arm, Kitselas, Skeena Crossing, Hazelton and other camps, providing as it would both steamship and rail facilities. The lumbering industry is also in its infancy. There are large areas of merchantable timber both in the interior and along the coast. Sawmills, shingle mills, box factories, etc., will be centralized at Prince Rupert in the near future. Along the route of the G.T.P. are to be had deposits of sand, clay, limestone and marble, only awaiting the advent of capital for their utilization commercially.

Drydock and Shipbuilding Plant.

One of the largest industrial projects on the British Columbia coast is that of the erection of a 20,000 ton floating dry-dock and shipbuilding and repair yards. This enterprise involves the expenditure of $2,750,000, and is under the name of the Grand Trunk Dry Dock and Ship Repair Co., a subsidiary of the Grand Trunk Pacific Railway. The work is well advanced and, with the completion of the necessary steel frame buildings and the floating dock, will be ready for business next year. A feature of the plant is that practically all the machinery has been manufactured in Canada. When in operation, it will give employment to from 300 to 500 skilled mechanics.

Water Powers.

Immediately surrounding Prince Ruper are a number of water powers that when developed will furnish the city with all the electrical energy needed for industrial purposes. At present the city is constructing the first unit of its proposed hydro-electric plant at Woodworth Lake at an initial cost of $380,000. This will provide 2,000 h.p. Up the North Arm of Wark's Channel (Thulme River). is to be had 10,000 h.p., and at Union Bay, Wark's Channel, is a similar horse power. The Hoessall river is estimated at 27,885 h.p. and the Khtada river 17,500 h.p. These two powers are owned by the Prince Rupert Hydro-Electric Company. At Port Edward, locally called "Prince Rupert's Industrial Annex" this company has erected a concrete power house and have now ready for installation two Diesel oil engines to develop 1,500 h.p.

In brief, the requirements for an industrial city, viz., the nearness to the

supply of raw materials, adequate means of transportation, reasonable cost of power, proximity of markets and labor are all to be had, or will be, in Prince Rupert and its vicinity. Prince Rupert wants fish curing and packing plants, cold storage plants, pulp, lumber and shingle mills, brick and cement manufacturers, smelter and refining works.

SASKATOON, SASK.

ALREADY there are several important manufacturing concerns located in Saskatoon, including the sole Western Canadian plant of the Quaker Oats Co. of Chicago, the largest concern of its kind in the world. A tent and mattress factory is also an important institution, producing an exceedingly high grade of mattress, which is largely sold throughout the West. In addition, Marshall, Sons & Co., of Gainsboro, England, one of the oldest British firms of tractor engineers, have an assembling plant located here in the vicinity of the Dominion Interior Elevator. The latter, which is expected to be ready for operation in November next, will have a storage capacity of about 5,000,000 bushels, and will cost in the neighborhood of $2,000,000. The Saskatoon Garment Co. is another rapidly developing concern, now employing quite a number of women and girls in the manufacture of overalls, working shirts, etc. There are several large wood working establishments, two highly equipped foundries and machine shops and numerous smaller manufacturers.

Regarding Saskatoon's strategic location from a manufacturing standpoint, it is only necessary, it is claimed, to place the finger on any reliable map of the West,—just where all the railways meet,—and to add that Sasakatoon's distributing territory extends to 48,600 square miles within which there are even now over over 200 thriving towns and villages on 2,225 miles of operating railways. Another point which ought not to be overlooked is that the operation of the new Hudson Bay route will bring this city—its natural prairie terminus—in very close touch with raw material in the form of steel, iron and coal from the East. The distance from Saskatoon to tidewater on the Hudson's Bay is 738 miles, while the distance from Saskatoon to Montreal is 1,894 miles. There is thus a saving of 1,156 miles of expensive railway haulage. This is advanced as a consideration that will convey its own significance.

WINNIPEG, MAN.

WINNIPEG, the capital city of Manitoba, has made wonderful progress since 40 years ago, when it was a Hudson Bay Co.'s trading post, and known as Fort Garry. A charter was granted in 1874, when the population was less than 2,000, whereas the present population is over 225,000, the assessment $260,000,000. Building permits for 1913 were valued at nearly $19,000,000, and bank clearings for the same year $1.635,000,000; truly a remarkable growth.

Winnipeg may well be called the Chicago of Canada, seeing that the grain business of the West centres there and its growth has been in a measure, similar to that of the "Windy City." Winnipeg is the most progressive city in the West. The citizens have taken full advantage of the opportunities presented and have shown commendable foresight in their efforts to keep pace with Western development. The city is laid out on modern lines and the public buildings are second to none in the Dominion.

Being the centre of a large wheat growing district, it is natural that Winnipeg should derive considerable importance because of this. In addition, large quantities of wheat and other grains from all over the country west of the "Peg" are dealt with on the Winnipeg Exchange. It is the distributing point for a large territory and headquarters of many wholesale houses, while a large number of Eastern concerns have branch establshiments in Winnipeg.

Winnipeg is an important manufacturing centre, and has a large number of factories embracing various industries. There are many features which combine to make this city a good place in which to locate a factory. First, cheap power is obtainable from the municipal hydro-electric plant on the Winnipeg River, where 60,000 h.p. is being developed. All the railways in the West converge in Winnipeg, giving the city excellent transportation facilities, a very important consideration for manufacturers. It is claimed that the C.P.R. yard, with over 150 miles of sidings, is the largest in the world controlled by a single corporation. The Union Station cost nearly $2.000,000.

Trade Gossip

War Grist.—The Nova Scotia Government a few days ago sent a message to His Royal Highness the Duke of Connaught stating that they would be glad to contribute one hundred thousand tons of Nova Scotia coal for such purposes as would best serve the interests of the Empire at the present time. The Governor-General replied, saying that he felt sure the patriotic and generous action of the government would be greatly appreciated. Sir Robert Borden wired in similar terms, and added that the offer had been communicated to His Majesty's Government. Landed at Halifax, this coal would be worth half a million dollars.

War Grist.—Some two weeks ago the Dominion Government sent tender forms to the various paint manufacturers for supplies for immediate delivery to be used in putting in the best of shape the Canadian cruisers Niobe and Rainbow. Brandram, Henderson Co., Montreal and Toronto, etc., received the order form and without waiting to think of specifications and prices immediately notified the Department that the firm would donate 40,000 pounds of white lead. To say that the splendid patriotism was appreciated by the Department would be putting it very mildly, as the price of white lead even before the war broke out was steadily advancing, and manufacturers were not booking a single order ahead.

The Russell Motor Car Co., Toronto has announced its intention to keep its full staff on its books, and is very optimistic regarding the stability of Canadian business. "We are endeavoring to keep every man employed, so that our workmen may not suffer to any considerable extent," says an official, "and we have no intention of laying off men or closing down the works. We feel that Canadians will be fair enough to support a Canadian industry which at a time like this gives support to Canadian workmen." In neither the automobile or bicycle department declares the Russell Co. has there been any falling off in the amount of orders, and they may have to hire additional men instead of discharging any.

To Oust German Trade. — The announcement of the Government regarding the capturing of Germany's export trade has been received with great enthusiasm by British traders, says a London, Eng., correspondent. With the view to replacing some of the larger markets in hardware and metals, a syndicate of British merchants have sent out by the S.S. Lake Manitoba a direct representative, P. G. Donald, who will act in the general interests of obtaining orders for some goods hitherto supplied by Germany for the whole of the English markets. "That Canada is alive to opportunities presenting themselves is obvious," says Mr. Donald, "from the prompt and courteous assistance given to us by the Canadian representatives on this side. It now merely remains for the Canadian Government and manufacturers to grasp the opportunities for the large trade to spring up between us."

R W. McConnel, of the survey staff, has been appointed as acting deputy, and will likely be confirmed in that position.

The General Market Conditions and Tendencies

This section sets forth the views and observations of men qualified to judge the outlook and with whom we are in close touch through provincial correspondents.

THE WORLD'S MONEY.

A DECIDED improvement has been manifested during the past week in the general financial situation, both on this continent and in Europe. The calmness with which the situation has been accepted in London after the first deliberate action and somewhat drastic steps taken by the directors of the Bank of England, is striking evidence of the implicit confidence of the business community in the financial strength of the British Empire, and this confidence is daily growing stronger on the recognition of the fact that the ocean trade routes are being maintained. Added to this, the remarkable strengthening of the cash position of the Bank of England, as shown by the last weekly statement, will help to allay any apprehension that may still be felt.

Montreal, Que., Aug. 24, 1914.—During the past week we seem to have passed the crisis, and in the business world there is awakening a new confidence. However, it is as yet only an awakening; nevertheless, it is significant in itself, and we can feel sure that, in as far as the business situation is concerned, the worst has really passed. Men at the head of our large industrial institutions have been able to adjust their policies to the new conditions. The meeting of the Dominion Parliament at Ottawa has had a great deal to do with the restoring of confidence. Our people have confidence in their national leaders, and with other added factors Canada seems in a fair way to receive a wave of prosperity.

The crisis, coming as it did on the heels of a hard time period, only serves the more to impress upon us the value of using sane and careful methods in business. Thus our new progress will be sounder and our prosperity more real. Canada as well as the United States cannot help herself from participating in better times right away. All trade with the Continent of Europe is very effectually cut off, while British trade is rapidly assuming normal proportions. There is, however, a new set of conditions prevailing. The German and Belgian competition is removed. The steel industries of Great Britain will have to supply the whole home demand. The iron ore mines of Britain cannot, however, supply that need, therefore from Sweden, Spain and Algeria more ore must come. The prices of all kinds of iron and steel will go up temporarily, and trade will be brisk. In the case of hematite pig, an iron used largely in the steel industry, the price has soared from 60s. to 72s. 6d. This high level will not, however, be maintained. The shipping interests will soon have their services adjusted, and a supply of imported ore will be brought into England in ample quantities to supply all demands. In Canada, shipments of British steel are arriving, but on account of the price having risen, the demand is not great. American and Canadian mills seem to be able to supply the trade with an equally good article and at a slightly lower price.

Pig Iron.

The supply of pig iron from Britain has practically ceased. Of course, small quantities are from time to time arriving, but no great amount has been received. The American and Canadian product seems to be filling all demands, and the price is remarkably steady. No large orders have been received, and there has really not been enough trade to make any real difference to prices.

The Steel Market.

More or less British steel has been received here in the last ten days, but there will not be much more, as home consumption will more than care for it all. The American quotations are rather varied. Some firms boost one line and not another. Thus the market is in a somewhat unusual position. Structural steel has taken about the highest jump, while sheet steel and thin plates have advanced the least. However, following the general tendency of the moment, there is no doubt but that the market will rapidly adjust itself, with prevailing prices somewhat higher than before the declaration of war.

Machine Tools.

There are very few sales reported, and these are all of a minor nature. However, with the new awakening, machine tools will undoubtedly participate in any improvement.

Metals.

The metal market remains very steady. Tin continues to sag a little, having dropped five cents in the last week. Copper dropped a little also. The sales for the week were, however, not large, and no really definite idea of the markets can be gained until the New York and London Exchanges are reopened.

Toronto, Ont., Aug. 25, 1914.—The unsettled conditions caused by the war do not show much improvement, and a great deal of caution is being exercised pending more favorable news from the scene of hostilities. The full effect of the war upon trade has hardly yet been felt, and it is impossible to foretell to what extent Canada will suffer. There is no doubt that we are becoming more accustomed to the unparalleled state of affairs, and so will be able to gauge the situation better and act accordingly. A considerable proportion of the war-scare depression is psychological and will be alleviated when news comes of a decisive victory by the allies; until then we must be calm and resolute, each doing his best to help things along.

It is unfortunate that some business concerns show a tendency to get panic-stricken, hardly warranted by the conditions; others, however, have expressed their intention of keeping factories open, if only on short time, an action which cannot be too highly commended. A species of scare seems to have taken hold of many to the detriment of those who are trying to instil more courage into the community. The situation is no doubt serious for the time being, compared with what we have usually been accustomed to, but the feeling is gaining ground that Canada stands to benefit by the conditions that will be created by the stagnation of industries in the countries involved in the struggle.

It must not be forgotten that the farming industry, which is the backbone of this country, will benefit appreciably by the war, as the Old Country can take all the foodstuffs that can be spared. Further, some industries should benefit by the elimination of the German export trade, although in a few cases the inability to obtain certain articles from that country will be a handicap; this no doubt will be satisfactorily adjusted in time. These conditions open up possibilities for new industries and Canadian manufacturers should get together and see what can be done to take advantage of the unique situation.

Considerable progress has been made towards restoring normal conditions on the Atlantic. Shipping facilities have improved considerably and schedules have been arranged for vessels trading between Canada and Great Britain; consequently the congestion at our Eastern ports has been considerably relieved and large quantities of foods have been shipped. Freight and insurance rates are both above normal, which is having a tendency to reduce the volume of shipments.

Steel Markets.

The condition in the markets for steel and allied products has not changed; consumers are watching developments and are not making contracts for the time being. Both the Dominion Steel Corporation and Nova Scotia Steel Company have decided to practically close down their plants, partly on account of the difficulty created by the war in shipping and financing foreign orders, and also because of the depression of the home market. These conditions may be relieved sooner than at present seems probable.

A representative of a syndicate of Old Country merchants is already on his way to Canada to ascertain whether manufacturers here can supply such materials as wire nails, iron gas and water pipe, etc. Large quantities of these products have in the past been imported from Germany, which market is now of course cut off. This indicates the possibility of interesting developments in the steel trade which may also eventually benefit from production being tied up in Europe.

Prices on steel products rule about the same, although as far as home production is concerned, there is hardly enough business being done to test the market. Firm prices can only be obtained against definite specifications and for immediate acceptance. Manufacturers are continuing to withdraw prices, and a return to original lists can hardly be expected for some time. The ferro-manganese situation is becoming serious, as the steel mills have not very heavy supplies of this indispensable material on hand, and it is impossible at present to obtain any from Europe. We understand that there may be a resumption of shipments by English makers next month, but how long this will continue is not certain. Some mills in the United States are confronted by a similar situation; the United States Steel Corporation is the most notable exception.

Pig Iron.

The pig iron market is very quiet. Owing to the unsettled conditions, the majority of foundries are operating at much reduced capacity and further, are not inclined to buy unless absolutely necessary. Some consumers have practically suspended operations altogether.

Machine Tools.

Business in machine tools continues very quiet; in fact it might easily be said that no business is being done. Consumers are no doubt holding off until the outlook improves.

Machinery Supplies.

With machine shops in many cases running at reduced capacity, few supplies are required, consequently business is quiet. Prices remain at the same level on all supplies except babbitt, which has advanced slightly. Prices on belting have not changed. Dealers handling English brands have stocks on hand and shipping facilities are getting better.

Tool Steel.

No fear may be entertained as regards obtaining tool steel. Most dealers have considerable stocks on hand and shipments have now been resumed from England. No change has been made in prices, but there is not much business being done.

Metals.

The metal markets are steady with prices practically the same as last week. Aluminum, however, has advanced 2 cents a pound. Tin is steady although the situation has not improved. The difficulty in obtaining this metal is largely on account of the difficulty in financing, and the British Government's restrictions on shippers. The tin market is sensitive and likely to continue to fluctuate in an erratic manner. The demand for most metals is dull, consumers covering for immediate requirements only. The antimony situation has not improved, although the price is steady.

The J. F. Brown Co., Ltd., has been authorized to manufacture copper and brass goods.

TRADE AND COMMERCE RECORD

Dealing With the Steps Being Taken and Progress Made by Industrial Canada To Achieve and Maintain a Dominant Place in the Markets of the World

DEVELOPING OUR EXPORT TRADE.

THE Canadian Trade and Commerce Department is making every effort to assist Canadian manufacturers in their intention to take advantage of the present European situation and capture the trade of Germany, Austria-Hungary and other countries which have ceased to manufacture as a result of the outbreak of war. In a bulletin issued to our manufacturers attention is called to the opportunities at their door.

"Evidence has lately come before the Department in the shape of remarks of several United States publications to show that the people of that country are realizing the opportunity that is presented for enlarging their export trade, now that active competition in the world's markets on the part of several European countries has been withdrawn as a result of the present war," says the bulletin.

"To a certain extent the arguments put forth by these publications are applicable also to Canada. While it is generally pointed out that an extended European conflict will prove of great benefit to Canada as a supplier of foodstuffs, the opportunity that is given to Canadian manufacturers to develop their export trade through the temporary withdrawal from the sphere of world trade of such countries as Germany and Austria-Hungary does not appear to be generally realized."

Trade Opportunities.

The bulletin then goes on to deal with various trade opportunities open to Canada. "First of all," it states, "as a result of the war Canada's direct trade with Germany and Austria-Hungary must necessarily suffer. In 1913 Canada imported from Germany goods worth $14,473,833, and she exported to Germany goods to the value of $3,402,394, a total trade of $17,876,227. With Austria-Hungary, Canada carried on a total trade to the value of $1,829,943, of which $1,674,349 consisted of imports and $154,594 of exports. It is thus seen that these countries, especially the former, had obtained a foothold on the Canadian market which will be lost during the progress of the present war. An opportunity is presented for other countries to increase their trade with Canada, or Canadian producers to make up a part of the deficiency thus created."

The British Market.

The foremost market of which Germany will be deprived as a result of the war is the United Kingdom, which has been buying goods from Germany at the rate of about $145,000,000 a year. German exports of agricultural machinery to Great Britain in 1913 were $131,189, as compared with $437,099 from Canada; of sewing machines, $500,000, as compared with Canada's $2,263. Under the head of machinery, Germany has exported to Great Britain to the value of over $5,000,000 a year; of electrical machinery, over $31,000,000 a year; of electrical goods and apparatus, $41,000,000 a year; hardware, $4,000,000; boots and shoes, $250,000; brooms and brushes $789,000, as compared with an import from Canada of only $7,917; of paper, $2,017,575, as compared with an import from Canada of $587,010.

Germany's trade with various British Dominions has also been large and here is an opportunity for Canadian manufacturers. Australia's purchases from Germany amount to over $32,000,000 a year, as compared with but $3,996,387 from Canada. South Africa imports $17,000,000 worth of German goods annually, as compared with less than $4,000,000 from Canada.

PAPER MARKET ACTIVE.

THE break in the shipping deadlock has afforded the Canadian paper companies opportunities to close profitable business for export in newsprint. Some big orders for shipment to England, South Africa and South America have been accepted by the Laurentide Company in the last few days. As an indication of the broadening tendency of the market J. H. A. Acer, treasurer of the company, states that inquiries had also been received from France and Italy.

The South American market is not a new one, but business in that direction has been small, Germany having supplied most of the trade. United States companies are now putting forth every effort to capture the market, but the opportunities for Canadian companies are there, and Laurentide at least is reaching out for some additional business.

Apart from the increased demand for export, the domestic demand has gone up at least 25 per cent. since the beginning of the month. Some trade authorities say the increase has been 40 per cent. The natural result has been rising prices and export business has been done on a basis of 2.50 f.o.b. Montreal, against 1.90 to 2 cents a pound before the war started.

Sulphite pulp continues strong, owing to the fact that the supply of 30,000 tons a month which used to go into the United States from Europe has been completely cut off. The quotation for sulphite is now $45 to $50 a ton, a rise of $10 to $15 a ton.

INCREASED OUTPUT OF ALBERTA COAL

THE very rapid development of the coal industry of Alberta is shown by figures which have just been compiled regarding the operations of coal mines in the province in 1913. Tons of coal mined in Alberta during 1913 numbered 4,306,346, being an increase of 859,997 over 1912. During the past eight years the coal output for Alberta has increased 500 per cent.

The Edmonton district has the largest coal fields, not only in Alberta, but in the Dominion. These areas are being opened up as fast as railway communications and capital make their operation possible. At the present time the Crow's Nest holds first place among the coal producing districts in Alberta, having an output of 1,849,435 tons. Lethbridge comes next with 966,020 tons; Edmonton third with 863,430 tons, and Calgary fourth with 627,461 tons. A large number of new mines were opened up during the year, mostly in the Edmonton coal field. Some of these were closed down again, on account of the fact that at the present time they are not served by railways.

Men Employed.

An increased number of men found employment in the mines of the province during 1913, the total number of men engaged in the mines, both above and below ground being given as 8,608. Machinery is coming to be used more and more in getting out the coal. In the lignite field more than half the coal is mined by machinery, but no machinery is used for coal cutting in the bituminous or anthracite fields. Twenty-nine mines are using electricity. Telephones have been installed in the larger mines, and are proving of great service, both in assisting the management and in obtaining assistance when accidents occur.

Mine rescue stations have been established, two in the Lethbridge district and the other between Coleman and Burmis. Others will be established

shortly in the northern part of the province. The stations are equipped with up-to-date apparatus and complete appliances for rendering first aid work very readily, 221 persons having presented themselves for training during the year, while 51 have been granted certificates for proficiency. There were 28 fatal accidents in mines in the province during 1913. Most of these occurred in the smaller mines.

STEEL PRODUCTS HAD GOOD YEAR.

THE first statement of Ontario Steel Products Co., the latest of the smaller Canadian mergers, reveals net profits of $106,437 for the first year of operation to June 30, 1914. These profits have been determined for the year, after providing for depreciation of properties, reduced market value of securities and the entire cost of organization. After meeting the bond interest of $36,000, the company earned 9.39 per cent. on its $750,000 preferred stock, on which a dividend of 7 per cent. was paid. This left $17,937 available for distribution on the $750,000 common stock, being equivalent to earnings of 2.39 per cent. Current assets are set down in the balance sheet at $472,062, being $353,149 in excess of the $118,913 current liabilities. Securities to the amount of $26,144 are included in the current assets. It is stated that these are set down at "market" prices, on July 1, 1914.

In view of general trade conditions it is surprising that net earnings should have held up so well. The year's net of $106,437 compares with the combined net earnings of the three factors in the merger in 1913 of $113,819. Income, however, has grown from $82,347 shown at June 30, 1910. Net assets, exclusive of good-will as at July 1, 1914, show a total of $1,211,481. Making up this total is the amount of $858,332, at which the real estate, plant, machinery and water power rights is appraised, together with surplus liquid assets over liabilities of $353,149.

TO KEEP THE FACTORIES OPEN.

TO keep the Canadian factories busy all winter and to keep our money in circulation at home is the object of a memorandum that has been forwarded to members of the Federal Government now considering Canada's greatest problem, that of keeping her workmen busy, even if at reduced hours, in order that they may earn something.

"Considering the reduced demand," says a prominent Canadian manufacturer, "and the stagnation of business, I am certain that if our people would demand Canadian-made goods my factory would be humming, and every other factory of its character in our country."

Attention is also drawn to other lines which are manufactured in Canada, and of the great importations from the States in similar trades. There was $500,000 worth of bath tubs, sinks and laundry tubs imported, mostly from the States, in the twelve months ending last March. There was $360,000 worth of labels for canned goods, bottles, shipping crates, etc. There was $90,000 worth of men's braces and suspenders. There was $250,000 worth of boots and shoes, $525,000 worth of drain and sewer pipes, $700,000 worth of brooms and brushes, $320,000 in baby carriages and toy sleds, $320,000 in collars and cuffs, $560,000 in ladies' corsets, $1,500,000 in clothing of various kinds, $400,000 in electric light carbons, $8,000,000 in electrical apparatus of various kinds, $1,000,000 in hardware. $700,000 in locks of various kinds, $125,000 in nails, and $900,000 in fence wire.

MAINTAINING EMPLOYMENT.

E. G. HENDERSON, of Windsor, Ont., president of the Canadian Manufacturers' Association, who was in Ottawa recently to see the Government in connection with business of interest to all the members of the association, intimates that every Canadian manufacturer is going to do everything possible to keep as many as possible in employment during the time the war is in progress.

"Our members are going to do this even if it means a sacrifice on their part," he said. "It is the duty of manufacturers to their country. In many cases it may not be possible to keep men employed on full time all along, but married men will be given the most consideration. The best way the general public can assist the manufacturers to keep their men employed is to buy Canadian-made goods as much as possible."

Robert Hobson, president of the Hamilton Steel & Iron Co., who was also in Ottawa at the same time, says that his firm is prepared to sell goods at a little below cost, if necessary, so that the purchase of their products will be made attractive. He looks for an improvement in the steel and iron business in Canada, owing to the production in Germany and other European countries being stopped to a large extent.

Personal

A. W. Ellson Fawkes, waterworks engineer of Calgary, Alta., will resign the position.

Captain T. C. Irving, Jun., vice-president of the Robt. W. Hunt & Co., inspecting engineers, Toronto, has left with the 2nd Company Canadian Engineers for Val Cartier, Que.

H. C. Cox, president of the Canada Life Assurance Co. has been elected a director of the Canadian General Electric Co. to fill the vacancy created by the death of his brother, the late E. W. Cox.

Prof. Reginald W. Brock, director of the Geological Survey of Canada, has resigned. He will become professor of applied science in the University of British Columbia.

Robert Hobson, president of the Hamilton Steel & Iron Co., Hamilton, Ont., says his firm is prepared to sell goods at a little below cost if necessary, so that the purchase of their products will be made attractive.

R. M. Hamilton, for many years general superintendent of the McGregor Gourlay Co. Works at Galt, has been appointed works manager of the Canada Machinery Corporation, Ltd., with supervision of the manufacturing departments of their various plants. His headquarters will be at Galt, Ont.

Tenders

Ottawa, Ont. — Tenders for public buildings, Peterborough, Ont., will be received up to Monday, September 14, 1914. Plans, specification and form of contract can be seen and forms of tender obtained at the office of Thos. Hastings, clerk of works, Postal Station "F," Yonge Street, Toronto, at the Post Office, Peterborough, Ont., and at Department of Public Works.

Ottawa, Ont. — Tenders for public building, Watford, Ont., will be received until Monday, September 14, 1914. Plans, specification and form of contract can be seen and forms of tender obtained at the office of Thos. A. Hastings, clerk of works, Postal Station "F," Yonge Street, Toronto, Ont.; at the Post Office, Watford, Ont., and at the Department of Public Works.

Advertising Service.—Manufacturers who advertise in the Trade and Technical press may be interested to learn that there is now in Canada an advertising and sales service devoted almost exclusively to their interests. Richard G. Langrill, a practical advertising man of over 12 years' active experience, and who is thoroughly familiar with the particular requirements is head of the concern which is known as the Richard G. Langrill, Advertising and Sales Service, with offices in the Dineen Building, Toronto.

Service Data for High Speed Bearing Loads and Velocities

By Gerald Stoney, F.R.S.

The observations contained in this article make a timely contribution to a subject that is more or less largely engaging the attention of designers and operators of high-speed mechanical engineering equipment in a wide field of application. The information given, being for the most part that obtained from test and experiment and actual service, carries with it, therefore, merit of exceptional value.

THERE are three principal types of friction in all bearings:—

1.—Contact friction, where both surfaces are dry, and this type was investigated as early as 1781 by Coulomb, who found for pressures from ¾ lb. to 100 lb. per sq. in., and speeds up to 10 ft. per second, that the friction was independent of the pressure per square inch and the velocity, but was proportional to the total force pressing the surfaces together, and was dependent also on the nature and material of the surfaces.

2.—Greasy friction, where there is more or less complete lubrication and a more or less complete film of oil between the surfaces. This has been investigated by many experimenters, but concordant results have not been obtained, as so much depends on the degree of lubrication. Generally speaking, however, friction of this kind is proportional to the load, and is independent of the speed—i.e., the coefficient of friction is constant.

3.—Complete lubrication where there is a complete oil film between the surfaces and there is no metallic contact, This usually occurs in high-speed journal bearings where bath or forced lubrication in some form is provided.

Experimental Results.

The chief published experiments on high speed bearings are those of O. Lasche, and the general result of his tests show that so far as friction is concerned it is not well to use a large shaft and a long bearing, although experience shows that for high speeds and heavy loads long bearings are necessary. They have also to be large to avoid vibration and critical speeds, and also the risk of fracture due to vibration. To avoid this latter danger the bending stresses have to be kept to a figure which would be considered very low in ordinary practice, as there have been several cases of fracture of shaft ends. If the pressure is too high, or the oil is too thin, a bearing may run all right so long as there is no vibration; but if vibration occurs, the oil film may be driven out and seizing takes place.

This is especially liable to happen with the staffs of electrical machinery, such as the armatures of dynamos and rotors of alternators, where there is always a liability to vibration due to their going out of balance; and it is probable that much lower pressures are advisable in such cases than in those of turbine rotors, which from their construction are not as a rule so liable to go out of balance. The effect is reduced in very high speed staffs, above say 2,000 revolutions per minute, by the use of the well known Parsons flexible bearing, where there are two or more tubes outside the bearing bush with a small clearance between them in which the viscosity of the oil tends to damp out vibrations.

Size of Bearings.

In turbine work, a rule much used for deciding the size of bearings has been that the product of the speed by the pressure should not exceed a certain figure, but it is doubtful whether this rule is of much value, as it really assumes greasy friction and not perfect lubrication. In land work a product of 5,600 has rarely been exceeded, or 75 lb. per sq. in. at 75 ft. per second. At lower speeds, higher pressures are used satisfactorily, as, for example at about 35 ft. per second a pressure of 130 lb. to 150 lb. per sq. in. is admissible.

In a discussion on Professor Christie's paper before the American Society of Mechanical Engineers in 1912, Hodgkinson stated that speeds of 80 ft. per second and 100 lb. per sq. in. were commonly employed in America, and where there is no risk of heavy vibration there does not seem any reason why higher pressures should not be used. It has to be remembered that the heat to be carried off does not increase with the pressure, and that the real danger lies in the possible breaking down of the oil film by excessive pressure or vibration.

Marine Turbines.

In marine turbines the journal speeds are much lower than on land, and rarely exceed 30 ft. per second, and the pressures are usually 80 lb. to 100 lb. per sq. in.; but there is a strong tendency to increase this latter figure, and it is probable that pressures of 150 lb., or even possibly 200 lb. per sq. in., could be used, especially if the oil temperature does not exceed 100 deg. to 110 deg. Fah., as is usual in marine work. The temperature of the oil is limited by its loss of viscosity at high temperature and by its liability to carbonize and oxidize, and thus cause deposit in the pipes, oil-ways, etc. In land practice temperatures of 120 deg. to 140 deg. Fah., are common, but it is not well to go above 150 deg. or 160 deg. Fah., as most oils seem liable to oxidize and cause deposit above this temperature. At about 250 deg. Fah. most oils cease to lubricate, as their viscosity becomes too low.

The Friction Feature.

From Lasche's experiments it was found that the friction is approximately inversely proportional to the temperature measured from freezing point; but after a certain temperature the friction rapidly increases and seizing takes place, due to the loss of viscosity. In all high-speed bearings artificial means have to be used to carry off the heat, radiation from the bearings not being sufficient. The general plan is to have such a flow of oil through the bearing as to cause the heat generated to be carried away without an undue rise of temperature. Water-jacketing the bearings has been used in some cases, but it is not as satisfactory in general as the plan of supplying sufficient oil to carry off the heat. Oil-coolers have therefore generally to be provided to cool the oil. In some cases also the oil is circulated round the outside of the bearing in suitable passages so as to assist in cooling it, and this is probably necessary in the case of very large bearings running at high surface speeds. The heat to be removed is not only that caused by friction, but also that caused by conduction from the steam; on the other hand, the bearings near the condenser are cooled by the exhaust steam and heated by the gland steam. From Lasche's tests the heat produced in bearings running at a temperature of about 122 deg. Fahr. is that due to a shear of the oil-film of about 0.46 lb. per sq. in. of the projected area, and this gives as the B.t.u. per hour:—

$$\text{B.t.u.} = 2.\ 1\ d\ l\ v$$

where d is diameter of bearing in inches,
l is length of bearing in inches,
v is surface velocity in feet per second.

The constant varies inversely as the temperature above freezing point. A formula which has been often used in marine practice is $\text{B.t.u} = d\ l\ v^{1.38}$, which gives slightly greater results for the usual speeds in marine work, and an oil temperature of about 100 deg. F.

It may be taken that this is approximately the heat that has to be carried off by the oil. Taking the specific heat of oil to be 0.31, and allowing a rise of

*From a paper read recently before the North East Coast Institution of Engineers and Shipbuilders.

10 deg. Fah. in the oil, we require 20 lb. or about one-third of a cubic foot of oil per hour per square inch of projected bearing surface when the surface speed is 30 ft. per second, and 40 lb., or two-thirds of a cubic foot, of oil per hour with a surface speed of 60 ft. per second. In practice these quantities are often increased by from 30 to 50 per cent., to allow of the unequal distribution of oil between the bearings, and to ensure that there is no undue heating, also in some cases to allow for the flow of heat from the steam.

Ring lubrication was experimented on by Lasche, but the results were found to be very variable, and in general he says that the tests show ring lubrication to be very uncertain and that it should not be used in cases where external cooling of the oil is necessary. As a result of some tests made on a 9 cm. diameter bearing, more oil came out of one side than the other.

Thrust Bearings.

Thrust bearings are generally of the usual collar type with the bottom and top halves separately adjustable to take up end play; and in land turbines, which are practically balanced, the pressures are very low, never exceeding 20 lb. per sq. in., and even in marine turbines 50 lbs. per sq. in. is never exceeded.

There are no tests available as to the friction of such bearings, but it is probable that it is fairly high, as perfect lubrication is difficult to attain, and, as an approximation, the total area—that is, the area of the top and bottom halves together—might be added to that of the main bearings in estimating the quantity of oil required and the surface of the oil-cooler. Such bearings have generally a high coefficient of friction, owing to the low pressures employed, since, as it is impossible for a wedging action to take place and thus admit the oil, such as has been described as occurring in the case of journal-bearings, the lubrication is rarely perfect. Towers found at moderate speeds that the pressure which could be safely carried was about 60 lb. per sq. in., as against 600 lb. in a journal-bearing, and that the shear resistance of the oil film was greater, being 1.5 lb. per sq. in., this giving about sixteen times the so-efficient of friction for a thrust-bearing as for a journal one.

The theoretical consideration of the conditions necessary for perfect lubrication, as set out in Osborne Reynold's Royal Society paper in 1886, referred to above, and also his own investigations, led Michell, in 1905, to devise a thrust-bearing which would admit of perfect lubrication. In this thrust-bearing there are segmental blocks pivoted at the theoretical center of pressure, which is about 0.6 of the length from the leading edge. By this device perfect lubrication is attained, and pressures up to 1,500 lb. per sq. in. can be safely carried at high velocities, with a consequent reduction of the coefficient of friction to about 1-60th of what it is in an ordinary thrust-bearing. Another advantage is that the end play in the thrust-bearing can be greatly reduced.

The same idea has been further developed by Sir Charles Parsons, K.C.B., F.R.S., in patent 8266 of 1912, where the blocks are centrally pivoted. It has been found that, in cases where the pressure comes on gradually, this works equally well in practice, and has the advantage that the shaft may run in either direction without the complication of shifting the point of support. These principles have also been applied to journal-bearings by Michell (patent 23,496 of 1911) and Sir Charles Parsons (patents 8,266 of 1912, 29,810 of 1912, 953 of 1913, and 5,619 of 1913), enabling greatly increased pressures to be used, with a resultant reduction of the coefficient of friction, and also a large reduction in the length of the bearings, and thus of the whole plant. The reduction of friction may in some cases reduce the consumption of steam between 1 per cent. and 2 per cent. in a turbine plant.

Ferranti (patent 5,035 of 1910) has also worked on the same lines, as well as Kingsbury in the United States (American Patent 947,242 of 1910), and there are full details of the latter's thrust-bearing in the Journal of the American Society of Naval Engineers, November, 1912.

In the U.S.S. Neptune a single collar, 13½ in. in diameter, carries 45,000 lb. thrust at 72 ft. per second mean speed surface, or a pressure of 500 lb. per sq. in. and, in general, such turbine thrust-bearings are designed for about 500 lb. per sq. in. at 60 ft. to 75 ft. per second. Much higher pressures can be safely carried, as is shown by some tests carried out by the Westinghouse Co., where pressures up to about 7,000 lb. per sq. in. at 54 ft. per second were carried without heating. The coefficient of friction of such a bearing may be from 0.0008 to 0.003 and, for such a pressure as 500 lb. per sq. in., may be safely taken as about 0.002, or, say, one-tenth to one-fifteenth of that of an ordinary thrust-bearing.

Steam Turbine Thrust Bearing Tests.

The Westinghouse Co., of Pittsburg, made an interesting set of tests on such a thrust-bearing for a steam turbine, the pressure being varied by throttling the balancing-pipe to the dummy piston. The following are the particulars of this bearing:—

Outside diameter of collar, 4¾ in.
Inside diameter of collar, 2⅜ in.
Number of pivoted blocks, 10 in.
Total area of pivoted blocks, 10.4 sq. inches.
Revolutions per minute, 3,470.
Mean surface speed, 54 ft per second.

The blocks were steel faced with white metal, 1-16 in. thick, and were pivoted behind their center of area, and with all the blocks in use, 1,010 lb. per sq. in. was carried without heating. As this was the limit of force which could be applied, the number was first reduced to four blocks, and then to two, the corresponding pressures per sq. in. being respectively 2,620 lb. and 5,420 lb. per sq. in., which were carried without difficulty. The surface was then reduced to 1.9 sq. in., and the pressure rose to 5,910 lb. per sq. in. It was further reduced to 1.2 sq. in., with a pressure of 10,000 lb. per sq. in., but here the white metal flowed in all directions until the area was increased so that the pressure was reduced to 7,000 lb. per sq. in., but no heating occurred.

It is worth noting that the white metal flowed equally in all directions irrespective of the direction of rotation. It is thus seen that the limit of pressure with such a bearing is the flowing of the white metal and not the failure of the lubrication, and that with pressures of 500 lb. per sq. in. there is an enormous margin of safety; it is probable that three times this pressure will be found quite safe in practice.

CANADIAN MOTOR CARS IN AUSTRALIA.

IN some of the Australian provinces there is no government registration of motor cars, hence it has only been possible to ascertain the number of cars and the names of the manufacturers registered in Victoria, New South Wales and South Australia. The total number of cars in these territories together with the proportion of Canadian cars, down to recent dates, is shown thus:—

June 30, 1914—Total motor cars in Victoria, 8,339.

June 30, 1914—Total Canadian cars in Victoria, 1,350.

May 21, 1914—Total motor cars in New South Wales, 13,901.

May 21, 1914—Total Canadian cars in New South Wales, 2,065.

May 15, 1914—Total motor cars in South Australia, 4,512.

May 15, 1914—Total Canadian cars in South Australia, 1,029.

Aggregating the three provinces, 26,752 cars were registered, of which 4,444 cars were of Canadian manufacture. Excellent direct representation, combined with the undoubted value of the leading lines of Canadian cars, is responsible for these encouraging results in face of competition in the Australian market of motor cars from all parts of the world.

Attracting Industries by Bonus or Concession

Staff Article.

Considerable rivalry exists in our towns and cities, large and small, in the matter of locating factories. Many and varied are the inducements offered prospective firms, bonus and concessions of some form or other being most common. Particular reference to these is here made.

THE policy adopted by municipalities of attracting new industries by means of concessions in some form or other is, on principle, questionable. If, however, the matter is looked upon from a purely business standpoint, then another view might be taken. It does not necessarily follow that if a policy is bad in principle that it is equally so in practice. It is to some extent a question of cause and effect—the reason why municipalities grant concessions and the effect produced on the community by so doing.

The basis of the whole question is really competition or, perhaps better still, rivalry. Take two towns equally advantageous as industrial centers; in the nature of things there is bound to be keen rivalry and, under present conditions it is only to be expected. Suppose a prospective industry comes along; the board of trade, backed by the town council at once get together and through their secretary or commissioner offer inducement or concessions in order to land the industry. The rival town also puts up an attractive proposition which usually brings both upon an equal basis again. The advantage, therefore, lies principally with the industry and partly with the town that gets it, although it might have located there anyway if neither town had offered extra attractions. It is reasonable to suppose, following the above argument that, all things being equal the towns would attract just as many industries without offering concessions as they would by doing so.

The system of granting concessions or a bonus is of comparatively recent origin, that is, since the country really began to make the industrial progress as we see it to-day. It is perhaps unfortunate that the system was ever introduced because it is extremely doubtful if it has done any real good in developing the trade of the Dominion. It is more than likely that the various industries now operating in Canada would be here just the same even if they had received no assistance. The representative of a concern, say in the United States, when looking for a suitable location for a Canadian branch, would not in the first case worry about free sites or cheap water, he would look for cheap power, a good railroad service, and accessibility to markets. If upon selecting a district, the industrial commissioner or board of trade secretary came along and offered further inducements, he would naturally accept them, but not locate because of the concessions. Apart from the concessions it is absolutely essential that a town should have an official ready to explain the attractive features of the district.

Bonus System.

The system of giving a bonus, which fortunately has almost disappeared, is not sound in principle and is open to abuse. More than one town regrets the day when it handed over a few thousand dollars to a third-rate concern, which only stayed in business long enough to collect the bonus and then died a natural death. Governments may be able to afford to nurse infant industries but municipalities should certainly not take such a responsibility even with a reputable firm for there is a danger of the bonus outweighing other and more important considerations; a condition which is at once detrimental to both industry and the community in which it is located. Firms of good standing do not look for a cash bonus, but rather for a location with natural advantages. A town that is a good distributing center, and that can offer cheap power and good transportation facilities does not have to give a bonus.

Bond Guarantees.

Another system sometimes adopted is for the municipality to guarantee the bonds of the prospective concern. This system, while not being in the same class as the above, is to some extent open to similar objections. It is obviously, however, a more business-like proposition that the proprietors of the company should take all the financial responsibility and it is certainly more conductive to good management and efficiency. There is a danger here for the management to think more about selling the bonds than the future of the business. There are exceptions, of course, but the above deals with the question from a general standpoint.

Concessions.

When considering the question of concessions, it should be borne in mind that from a manufacturing standpoint, industrial centers differ as regards natural advantages although in some cases they are often very similar. The method of dealing with prospective industries must naturally vary according to conditions. In actual practice, however, the majority of our cities are working along very similar lines. Assuming that it is necessary, owing to competition, for a city to offer concessions, care should be taken that too much is not given away. Where cheap power is available together with good transportation facilities, including of course, low freight rates, and accessibility to markets, then surely that is about as much as any company can reasonably expect. There are many industrial centers in Canada which can offer all the above inducements but on account of this civic rivalry, the board of trade, the authority usually in charge of such matters, comes along with concessions generally in the form of a free site, cheap water and either remissions of taxes or a low assessment for a term of years. Now the point is, does the city really benefit by the concessions or rather would it not get along just as well without giving these extra inducements? Would not the industry flourish just as well without the assistance of the concessions? Is not the bait really unnecessary? One would almost think that it was quite unnecessary, but here is where the rivalry comes in. If one town offers concessions so will the others.

The promoter of a high class company will naturally take all he can get without, of course, sacrificing any material advantages such as many localities offer, but in some cases the concessions do not cut much of a figure, the natural advantages being pre-eminent. In many cases everything counts and consequently there is much rivalry between our various municipalities. The fact that free sites and cheap water, etc., do not involve any considerable financial outlay on the part of the community and on the surface do not appear to amount to much, may lead the people into thinking that they are getting something for nothing, hence a large favorable majority when the by-law comes to be voted on. If the industry be of a substantial nature the gain to the city is considerably more than what the concessions represent, as it means, in many cases, a considerable increase in population and consequently so much more money locally distributed. In the case of small industries, the advantage is proportionately less.

Civic Rivalry.

It is a debatable point, whether civic rivalry as regards industries is advantageous to the community generally. If municipalities relied upon their natural advantages for development, would not more stable conditions result and would not the industries be as well off? It is more than probable that if no artificial means were employed, industries would naturally gravitate to the most suitable locations, which is not always the case

under the present conditions. It would appear to be an advantage to the country if those localities which had legitimate attractions for industries should develop as industrial centers rather than have factories scattered about in districts where they have a struggle for an existence. It is better for industries generally to be more or less concentrated at several logical locations where they can help one another in many ways. There are exceptions, such as pulp and paper mills and industries doing, what might be called, purely a local business.

The system of granting concessions exists in practically all our industrial centers, except the larger cities whose natural advantages are such that further inducements are unnecessary. The time may come when the system will no longer be popular, for there are signs already that this may come to pass. Our industrial centers are not nearly as extravagant in their offerings as formerly, which is a good sign. Localities that really have the necessary facilities for manufacturers will surely develop, while those that have not and that have been boomed by some extravagant concessions will gradually find their legitimate level. This process of weeding out will result in our manufacturing centers developing on substantial lines and so benefit the country generally.

ENGINEERING AS A PROFESSION.

ANTHONY G. LYSTER, president of the Institution of Civil Engineers, and late engineer-in-chief to the Mersey Docks and Harbor Board, made some significant remarks on modern engineering prospects when distributing the certificates on its 125th celebration, to the Crystal Palace School of Engineering students, recently.

He said that after 44 years of wide and strenuous experience in the engineering world he hoped to be able to say something to the students that might be of help in their future careers. He could not help drawing a comparison between the opportunities afforded to him as a young man to learn engineering and those which students enjoyed to-day. In his days text books on engineering were practically unknown. Students had to pick things up the best way they could, and engineering was carried on by rule of thumb methods and a few cut and dried formulae. How different things were to-day, when students could obtain a sound scientific and practical grip from the very commencement of their studies.

While congratulating the school on its good results, he hoped students would continue to make the best of the fine opportunities they had there. They had to cultivate first of all a sense of observation, and a desire to find things out for themselves in a practical way. It was a common fallacy to believe that if a man dropped right away into a post at £1,000 a year he had all he wanted, for they had to go on moving and fighting for better things because it was new experience that was of the greatest value to engineers. The problems they had been studying were solved from a collection of data all ready for them, but they would find in the actual problems of practical engineers that they had to get their own data, and it was only real experience which helped them to get that. They had to diagnose and analyse, and never make the mistake of getting their opinions formed before they gathered the facts. People told them to-day that the engineering profession was very full, but he remembered just the same thing was said to him 4 years ago; it was not true, and they must not let such things dishearten them.

Difficulties of Employment.

It was a fact that as civilization was spreading throughout the world there was more difficulty for engineers to get work in this country. In fact, it was only those who were able to get to the top who could find decent jobs. In the colonies, in Egypt, and in India, from whence he had just returned, there was a vast field of enterprise all waiting for engineers to expand and do well in. Every day the world was adding to its information as to what was the best way of using the great forces of Nature, of which they knew so little at present. In the future it was the engineer who was going to be able to take advantage of that information and put it into practical effect.

In conclusion, Mr. Lyster made some remarks to the students on citizenship. They must never, he said, let their profession obliterate the fact that their first duty was to be good citizens. To-day they were face to face with a very serious situation in Europe, and they could see what it meant for every young man to take a part in the defence of his country. When he was completing his engineering education in Germany, the Franco-Prussian war was in progress, and he never saw such striking examples of the vast importance of being prepared. When he came home, he at once joined the Volunteers, and he hoped all young engineers to-day would join the Territorials.

CANADIAN STEEL OUTPUT.

MANUFACTURERS' statistics of the steel output of Canada are now available through the Statistical Bureau of the American Iron and Steel Institute, and these cover the production of steel ingots, castings, and all manner of finished rolled forms of iron and steel during 1913. The production of all kinds of steel ingots and castings in Canada in 1913 amounted to 1,042,503 gross tons, against 853,031 tons in 1912, an increase of 189,472 tons, or over 22.2 per cent.

Of the total in 1913, about 1,006,149 tons were ingots and about 36.354 tons were direct steel castings, against about 820,792 tons of ingots and about 32,239 tons of castings in 1912. The production of steel ingots and castings in 1913 was much the largest in the history of the Dominion. The growth in late years has been very rapid. Since 1908 the output has increased over 100 per cent. The total for 1913 includes about 1,852 tons of alloy-treated steel castings, against about 1,294 tons of similarly treated steel ingots and castings in 1912.

In 1913 there were sixteen plants in four provinces which made steel ingots or castings, as compared with fourteen plants in four provinces in 1912. The number of idle steel works in 1913 was four, as compared with three in 1912.

The production of Bessemer and steel ingots and castings in 1913 amounted to 273,391 tons, against 207,569 tons in 1912, an increase of 65,822 tons, or over 31.7 per cent., while the production of open-hearth steel ingots and castings in 1913 amounted to 768,663 tons, against 645,062 tons, or over 19.1 per cent. Almost all the Bessemer steel made in the two years was in the form of ingots.

Of the total production of open-hearth steel in 1913, 736,562 gross tons were ingots and 32,101 tons were castings, against 617,061 tons of ingots and 28,001 tons of castings in 1912. In both years, all the open-hearth ingots were made by the basic process, but the castings were made by both the acid and the basic processes. One plant made steel by the duplex process in 1912 and 1913.

The total production of steel ingots only in 1913, omitting direct steel castings, amounted to 1,006,149 tons, against 820,792 tons in 1912, an increase of 185,357 tons, or over 22.5 per cent. In 1913 there were six plants in two provinces which made steel ingots, against four in two provinces in 1912.

The total production of all kinds of steel castings in 1913, omitting steel ingots, amounted to 36,354 tons, against 32,239 tons in 1912, an increase of 4,115 tons. Of the total output in 1913 about 3,809 tons were made by the Bessemer process, against about 3,838 tons in 1912; about 32,101 tons were made by the open-hearth process, against about 28,001 tons in 1912; and about 444 tons were made by special processes, against about 400 tons in 1912.

In 1913 there were thirteen plants in four provinces which made steel castings, against twelve plants in four provinces in 1912.

PRODUCTION METHODS AND DEVICES

TURRET LATHE AND VERTICAL BORING MILL PRACTICE.—V.*

By Albert A. Dowd.

THE present forms the concluding article of a series on turret lathe and vertical boring mill practice, the setting and sequence of operations required in machining an automobile hub flange being featured.

Machining a Hub Flange on the Vertical Turret Lathe.

Fig. 9 shows a representative hub flange A, the method of holding and the layout of turret and side head tools. The work is held in special jaws B which are slightly tapered at C to conform to the draft on the casting. The flanged portion is supported at three points by the projection D on the jaws. A tool holder E of special length contains a high speed round nose tool F, the stem of the holder fitting the turret hole and being there provided with a pin driver as hereinbefore described. The boring bar J contains two tools, L and K, which are angularly set in the bar and possess backing-up screws M, by means of which the tools may be nicely adjusted for diameters. The square head set screws N hold the tools firmly in any desired position. The spacing of the two tools is such that the first tool L is entirely

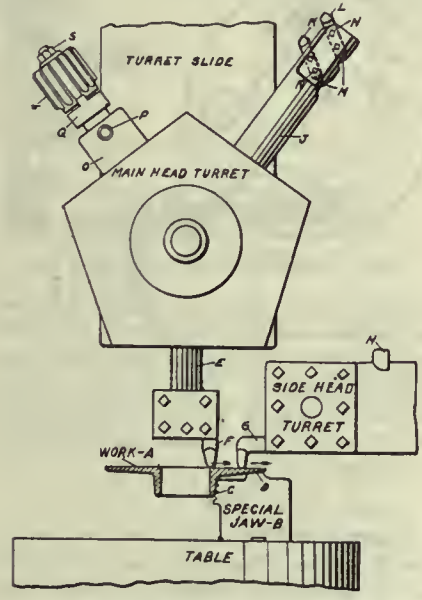

FIG. 9. MACHINING HUB FLANGE ON VERTICAL TURRET LATHE.

through the work before the second one K starts. The reamer T is of high speed steel and slips on to the tapered end of the arbor Q, being held in position by the nut S. The shank of the reamer floats in the holder O, which fits the turret hole and it is driven by the pin P. The two bent tools G and E in the side head turret are respectively roughing and finishing tools

*The former articles of this series appeared in our July 30, August 6-13 and 27 issues.

Sequence of Operations.

First operation:—The tools shown in contact with the work in Fig. 9 are those

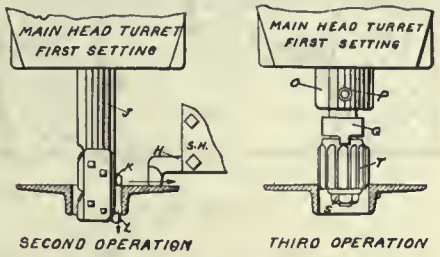

FIG. 10. MACHINING HUB FLANGE ON VERTICAL TURRET LATHE.

used in the first operation for rough facing the surface of the flange. In order to save time, the tool F is started on the inside of the flange at the same time that the tool G in the side head turret starts midway across the flange. Both main head turret and side head are fed outward at the same rate of speed, so that the time for facing the flange is cut approximately in two.

Second operation:—Fig. 10 shows the second operation, which consists of the rough and finish boring of the hole with the bar J in the main head turret. Prior to the starting of the bar the finishing tool H in the side head is started in the hole, and fed outwardly at a coarse feed. As soon as the heel of this tool has cleared the hole, the bar is started and the down feed is continued without interruption until the hole has been finish bored. It will be noted that by the use of this bar one indexing of the turret is saved.

Third operation:—The third and last operation on the piece is that of reaming the hole with the floating reamer T in the main head turret.

The tooling here given for the flange is extremely simple, but very rapid and effective.

MAKING SHEET METAL FLANGE CLAMPS.

By W. G.

THE tools herein described were used for producing aluminum clamping flanges in quantity for friction discs. It was at first decided to cast and machine them in the usual way on a capstan lathe, but, after some consideration, it was determined that the press would be the most economical and expeditious tool for the job. Upon this being settled, the necessary punches and dies were made as shown.

With reference to the accompanying drawings, Fig. 1 is a part sectional view of the cupping punch and die in working position. The piercing punch and die are shown in Fig. 2. Fig. 3 is a part sectional view of the flange trimming punch and die, and Fig. 4 shows elevation and plan respectively of the plate jig for drilling the bolt holes in the flanges. The cupping punch A (Fig. 1) is made from tool steel, and consists of a circular bar, having formed near its centre an enlarged shoulder or abutment collar A^1. The said collar has upon its lower face four shallow recesses, as shown, for the purpose of receiving the springs for operating the pressure plate. Part A^2 is the shank, which should be made of suitable diameter to fit the hole in the press ram. The opposite end A^3 is fitted with an elongated slot as shown, its object being to act in conjunction with the pin B^1 of the pressure plate B, thus making a stop for the plate when at its

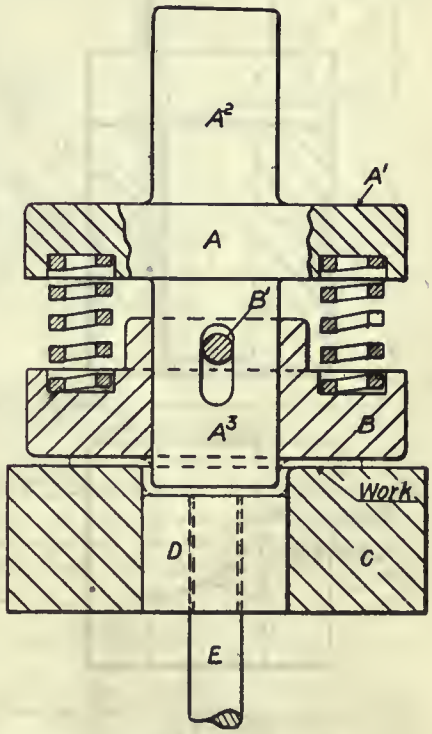

FIG. 1—FORMING PUNCH AND DIE.

bottom position.

Part C is the cupping die. This is made from tool steel, and consists of a circular blank, having a central hole of a diameter corresponding to that of the

outside of the component. At D is shown the distance and ejector block. This should be made of good quality mild steel, surface hardened and ground. It is essential, however, that it should be a free sliding fit to the die hole, otherwise difficulty will be experienced when ejecting. The knockout rod E is screwed into the block, and is operated from below by the usual treadle gear.

The sequence of operations by the cupping tool is as follows:—The plain circular blank is placed on the face of the die C, and when the punch A descends, the pressure plate B being foremost, strikes the blank first, thus securing it to the die face. The punch continuing its downward movement, forces the central portion of the blank into the die until it reaches the face of the distance plug D. The punch and pressure plate now return clear of the die, leaving the component cupped and flanged, ready for removal by the upward motion of the distance plug.

The piercing tools, Fig. 2, consist of a tool steel punch F surrounded by a hard rubber stripper G. The die H is made from a circular bar of tool steel equal in diameter to the inside of the component; thus the die itself forms the

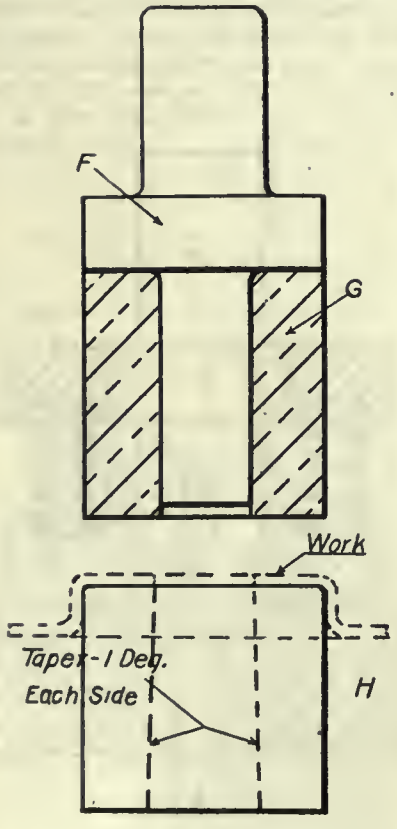

FIG. 2—PIERCING PUNCH WITH RUBBER STRIPPER.

necessary means of location. The trimming tools, Fig. 3, are of simple construction. The punch I is of the usual **blanking** type, and is provided with the pilot peg J. The trimming die K consists of a circular tool steel blank, having a central hole K^1 equal in diameter to the flange of the component. It is essential that the said hole should be

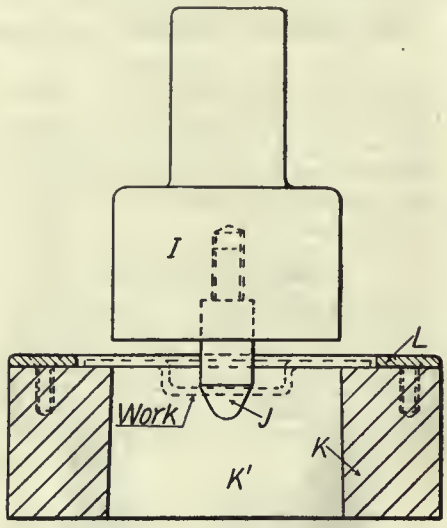

FIG. 3—TRIMMING PUNCH.

tapered in order to allow the work to pass through clear of the die, it having been found that a taper of 1 deg. on each side is ample for this purpose.

Part L is the locating ring, which is made of mild steel and secured to the die by screws, as shown. The hole in the ring should be somewhat larger than the irregular flange of the component, its object being only that of approximate location, the final accurate location being performed by the pilot peg J. The finishing operation (drilling screw holes in the flange) is carried out by means of the drill jig shown in Fig. 4. The jig body M consists of a mild steel disc, having bored through its centre a hole M^1, and for the purpose of locating the component, as shown, this hole must be a good sliding fit for the flanges. The projecting piece N is the clamping screw, which has a knurled head a little larger in diameter than the screw stem, the object of this being to prevent any undue leverage when clamping; otherwise it may have a tendency to badly mark or damage the work. The drill bushes O, P, Q and R are made from best cast steel, and are hardened and ground, care being taken to see that they are made a good driving fit to the corresponding holes in the jig body.

THE APPRENTICE QUESTION.

By R. Micks.

THE apprentice of to-day is the mechanic of to-morrow, and if he is not given the proper opportunity to acquire a knowledge of the different branches of the trade he has chosen to follow, we cannot look for a goodly number of first-class mechanics among those of the next generation. When a boy enters a foundry or any other manufacturing department to learn a trade, he should be encouraged and shown some consideration, for the work itself may sometimes be such as to daunt stout hearts and, if he be ambitious, he will soon amply repay one for the time and trouble expended.

In a large number of foundries which have come under the observation of the writer, the junior apprentice is little more than the moulder's little dog. Most of the rough, dirty work—and there is plenty of it—is turned over to him. This in itself is enough to discourage any boy, not to mention one of intelligence and self-respect, for he could learn to use a shovel quite thoroughly in a sewer at a much higher wage.

After an experience involving the raising of a great number of apprentices, the writer is in favor of giving each one a thorough training in all branches of the work, including core making, bench and floor moulding. As a result of mechanical changes in foundry methods, the good, all-round jobbing moulder is on the decrease; therefore, to fill all requirements his education should embrace cores, melting and other branches, as well as pounding sand.

The handy man is quite satisfactory on certain classes of routine work, but we must always have the experienced moulder on jobbing and intricate machinery castings if we would continue to produce good work. The chemist has done much for the technical end of the

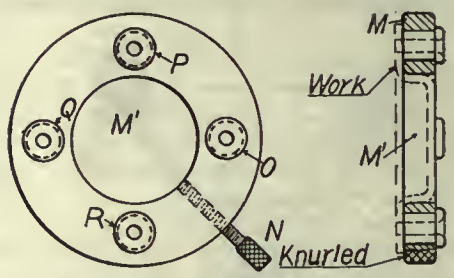

FIG. 4.—JIG FOR FLANGE HOLES.

foundry, but it remains for the foreman and superintendent to provide the good and thorough mechanics who are absolutely necessary. This is best accomplished by giving first consideration to the material, the diamond in the rough, the apprentice.

Pump Orders.—The Smart-Turner Machine Co., Hamilton, Ont., have recently closed the following orders for pumps:—The Cobalt Lake Mining Co., Cobalt, Ont., one centrifugal pump; the Deloro Mining & Reduction Co., Deloro, Ont., one centrifugal pump; the Canadian Porcelain Co., Hamilton, Ont., one centrifugal pump; the M. & M. A. Deans Co., Sprucedale, Ont., one duplex steam pump.

Arithmetic for the Machinist and Workshop Operative

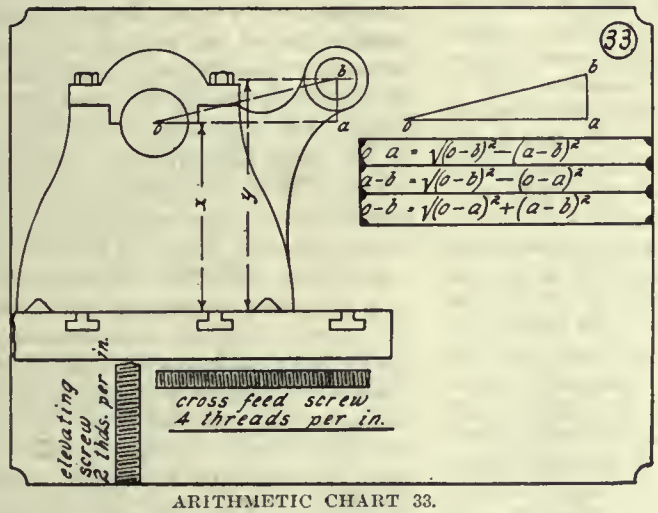
By J. H. Rodgers

With the further development of this course in arithmetic, it will be found by those who have followed the introductory lessons and profited by them that the various practical applications resulting from the succeeding lessons will be easily observed and their time and labor-saving features so appreciated as to be adopted at every available opportunity.

FEEDS.

IT often happens that lateral and vertical movement is required when adjusting the position of parallel holes in machine frames when being operated on the boring machine, etc.

In the skeleton sketch chart 33, the line o-b equals the distance between the centers of the two holes; the line o-a the horizontal distance or lateral feed of the table, and the line a-b the vertical distance or elevation of the table. The formulae shown in the chart can be used for general cases. In chart 33, suppose the distance o-b was required to be the center distance of two gears of 72 and 24 teeth of 6 diametrical pitch or 8-in centers, the distance o-a=7.75 inches and the height x=12 inches, what will be the height (y), and the movement of the vertical and horizontal screws, if each division on the vertical adjustment moves the table .002 in. and each division on the horizontal adjustment moves the table .001 inch?



ARITHMETIC CHART 33.

The divisions on each disc being 100, center distance or o-b=8 in., and horizontal distance or o-a=7.75 in.

By formula

$a\text{-}b=\sqrt{(o\text{-}b)^2-(o\text{-}a)^2}=\sqrt{8^2-7.75^2}=\sqrt{64-60.6625}=\sqrt{3.9375}=1.984$ inches.

Then $y=12+1.984=13.984$ inches.

By formula, chart 32, for lateral feed:

$$M=\frac{N\times G\times d}{P}\times E=\frac{4\times 5\times 100}{2}\times 7.75=$$

7,750 divisions or 77 turns and 50 divisions.

For vertical feed

$$M=\frac{N\times G\times d}{P}\times E=\frac{2\times 5\times 100}{1}\times 1.984=$$

1.984 divisions or 19 turns and 84 divisions.

In chart 34 is shown a skeleton sketch of a machine where a head (not shown) is advanced by means of a nut on the screw (S), through a distance governed by the train of gears shown. The motion is intermittent; that is, the screw (S) is in motion while advancing the head and at rest while other operations are being performed. The screw (S) has a pitch of ½-inch. The pinions (PP) have 20 teeth, the gear (G) has 80 teeth. What number of teeth should gear (E) have to advance the head ⅝-in. for each revolution of the clutch (C); the bevel gears being of equal size?

The revolutions of the clutch (C) × the number of teeth in gear (E)=the number of teeth pinion (P) × the revolutions of screw (S), or

$$\text{Gear E}=\frac{\text{P}\times\text{rev. of S}}{\text{rev. of C.}}$$

For solution of above problem:

$$\text{rev. of S}=\frac{5}{8}\div\frac{1}{2}\text{ or }\frac{5}{8}\times\frac{2}{1}=\frac{5}{4}.$$

$$\text{Then gear E}=\frac{20\times 5\text{-}4}{1}=20\times\frac{5}{4}=25$$

teeth.

What gear would be required to advance the head in the previous example through a distance of 1⅛ in. for every revolution of the clutch (C)?

$$\text{Gear E}=\frac{20\times(1\frac{1}{8}\div\frac{1}{2})}{1}=$$

$$\frac{20}{1}\times\frac{9}{8}\times\frac{2}{1}=45\text{ teeth.}$$

QUESTIONS AND ANSWERS FOR MECHANICS.

Question—A milling machine man receives a gear blank 14 inches in diameter, with orders to cut it 3-pitch. How many teeth should he set his dividing head to space?

Answer.—From the previous rule to find the outside diameter, which is, add 2 to the number of teeth and divide by the pitch. For the number of teeth, multiply the diameter by the pitch and subtract 2, or number of teeth=(14×3) —2=42—2=40 teeth.

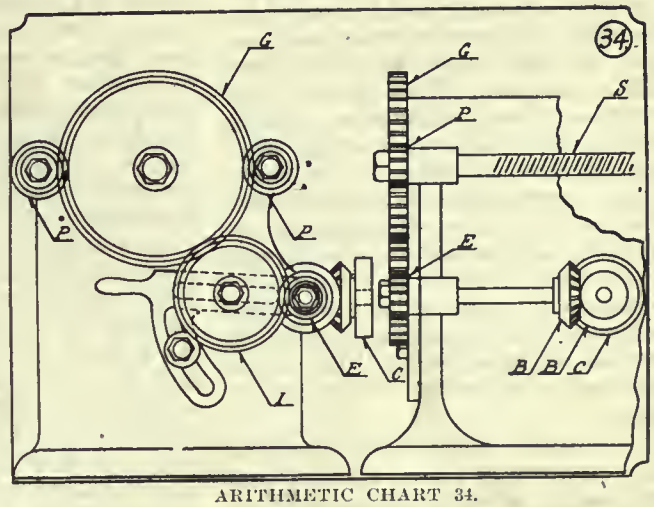
* * *

Question.—The pitch diameter of a gear is 18 inches, what should be its outside diameter if it be 2-pitch?

Answer.—$\text{Addendum}=\frac{1}{\text{pitch}}=\frac{1}{2}$ inch

Outside diameter = pitch diameter + twice the addendum or outside diameter of gear

= 18+½×2=18+1=19 inches.



ARITHMETIC CHART 34.

Question—If the pinion which gives the traverse motion to a lathe carriage have 16 teeth of 10-pitch, supposing it to be geared 2 to 1 with the handle, how far would the carriage move for each turn of the handle?

Answer.—Diametral pitch = 10, therefore circular pitch $=\frac{3.1416}{10}=.31416$ inch.

For every turn of the handle the pinion makes half a turn, therefore total distance covered by carriage is $.31416\times\frac{16}{2}$

= 2.51328 inches.

SAFETY IN TUMBLING MILL OPERATION.

IN cleaning rough castings by the use of dry tumbling mills or tumbling barrels, large quantities of dust are created as the castings tumble about and rub against each other. This dust must be properly taken care of so that it may not produce an injurious effect upon the health of employes working about these machines. In addition, tumbliug mills must be provided with appropriate safeguards to overcome mechanical dangers incident to operation and use. The physical condition of the foundry and the construction of the tumbling mills themselves will largely determine how best to solve the dust problem. One of two methods will however, be found applicable to all cases:—a suitable exhaust system may be employed to carry off the dust, or each machine may be enclosed in a separate dust-proof compartment.

The use of an exhaust system is most desirable, as it carries the dust away from the machine to a place outside of the building; exhaust systems, however, can be installed only upon mills which have been expressly built for exhaust connection.

Dust Proof Compartments.

If the machines are of the non-exhaust type, the dust danger can be averted by providing dust-proof compartments in which the mills can be entirely enclosed while in operation. When the mill is located away from partitions or walls, or where a high compartment would interfere with proper lighting of the workshop or consume head-room valuable for other purposes, these compartments are built only high enough to accommodate the machine; otherwise they are usually built against existing walls or partitions and right up to the ceiling, thereby increasing air space within the compartment and facilitating the settling of dust.

For small compartments, the doors may be arranged to fold upward and lie upon the top of the compartment when the mill is at rest. For most machines, however, the size and weight of the doors will require that they be suspended on rolling door-hangers to slide horizontally if there is ample side room, or to slide upward if side space is limited. Steel rolling shutters are sometimes used instead of rising doors. The whole compartment should be tightly built of well-seasoned lumber to prevent excessive shrinkage and warpage, and the doors should be well fitted to insure fairly tight joints and ease of operation. Rising doors, to avoid falling upon workmen, must be carefully counterweighted, or provided with a suitable automatic latch, or both.

Guarding Against Mechanical Hazards.

While, obviously, there is no dust problem in the operation of wet tumbling mills, the mechanical hazards of both wet and dry mills must be guarded against alike, unless the mills are enclosed in dust-proof compartments during their operation, in which case only external belts or driving chains may need to be covered by appropriate guards. When not enclosed, tumbling mills present mechanical hazards which may lead to serious consequences. The corners of square box tumblers, or protruding fastenings or flanges on round or stave type mills, or even nails, slivers or core-rods which may work through perforated or loosely fitting cover plates, are apt to strike the workman or catch in his clothing. Exposed gears, belts and driving chains are additional potential sources of accidental injury. With a comparatively small expenditure, however, all of these dangers may be effectually safeguarded.

Although the workman's personal caution and watchfulness is always his own most effective protection, the mill itself should nevertheless be so guarded that the workman may not easily come into contact with it while it is running. Suitable guard rails or fences, made of pipe, heavy wire screen or wood erected at the exposed sides of tumbling machines and provided with a rising screen gate in front, will prevent contact of workmen with the machine when it is in motion. When rising gates may not be practicable, suitable doors may be arranged to slide horizontally, or removable wire screen guards fitting into pipe-rail sockets, may be used.

An automatic connection between the gate and the operating lever of the machine, whereby the opening of the gate will stop the machine, or the starting of the machine will close the gate, will render the machine inoperative when workmen are engaged in loading or unloading the barrel, and will keep workmen at a safe distance when the machine is running. In any event, whether controlled by gates or otherwise, such levers should be of the positive locking type, to prevent the levers from creeping over and starting the machine prematurely.

Accident Data.

Observation and study of accident reports show that workmen's fingers and knuckles are often injured when they remove or replace tumbling mill covers by hand, and many foot injuries are traceable to the falling of such covers upon workmen's feet. A light chain hoist suspended from a short trolley track above the machine and equipped with hooks to fit the cover handles, will tend to prevent such accidents and at the same time facilitate the work. The hoist may also be used to load and unload heavy castings in and out of the mill.

To prevent accidents caused by slight movement of the mill while it is being loaded or unloaded, a suitable locking device or brake should positively lock the barrel in position; each foundry foreman can devise an effective brake to suit the conditions peculiar to his own equipment. The usual method of propping the barrel in place with a bar is not reliable, as it is apt to be kicked or jarred out of place. Finally, foremen and workmen should see that clear passageways are maintained in front of and leading to tumbling mills.

In the nature of their construction and operation, tumbling mills present problems of safety and sanitation which require some thought for their solution, yet proper attention to the matter will develop effectual guards against the inherent dangers of tumbling mill operation, and at the same time the cleaning room can be made a reasonably clean and attractive workshop.—N.F.A. Bulletin.

New Vibratory Testing Machine.—A description of a new vibratory testing machine formed the subject of a paper before the recent annual convention of the American Society for Testing Materials. For a number of years several of the large railways have included a vibratory test requirement in their specification for stay-bolt iron and other large consumers, while not actually purchasing iron under such a requirement, have given the property to resist vibratory forces marked consideration in placing their contracts. A study of the machines and methods of testing by the Committee on Stay-bolt and Engine-bolt Iron of the Testing Materials Society indicated that the erratic results frequently obtained from specimens cut from the same bar and tested on the same machine, were due to the fact that the specimens, although apparently perfectly rigid in all cases, were held with different degrees of rigidity; furthermore, the root of the thread of bolts differed to such an extent in sharpness and smoothness as to exert a pronounced influence upon the number of vibrations the specimen would withstand. It was with a view of securing a machine that would overcome these difficulties and which would also permit making such tests rapidly with a high degree of accuracy, that the machine described was developed.

Welding Processes and Their Development*

Staff Article

A brief sketch is here given of the means and methods employed in the manufacture of mechanical apparatus, whereby a more or less permanent, uniform and sufficiently reliable attachment for a specific purpose has been attainable between two metals. The more recent developments in oxy-acetylene welding are especially featured.

FROM prehistoric times down to the present the art of welding has been employed, yet until the middle of the nineteenth century very little study had been given or research employed to this particular branch of the metal industry. During the last decade the adoption of sheet metal has become very marked, and the use of metals generally has become so extensive that their present field is almost unlimited. Thus, as this industry became enlarged, the methods of metal production improved along nearly all lines. Right to the mines the campaign of efficiency was pushed. Mining machinery was more largely pressed into service, and processes became simpler. Still, through all these marvellous improvements, the process of welding improved but little. Again, the popular idea has been that welding could only be applied to the process of joining pieces of iron and steel. Scientific research, however, conducted by eminent engineers in Europe has not only made the oxy-acetylene process of autogenous welding commercially practicable, but has enlarged the field tremendously, because it has now been practically demonstrated that numerous metals can be successfully treated under the autogenous welding principles.

Soft Soldering.

In order to appreciate thoroughly the fundamentals of autogenous welding, it is useful to briefly look into the other methods of obtaining permanent metallic joints. Soft soldering is generally used for joining pieces of thin metal together. It does not, however, make a strong joint, being used where the prime consideration is an air or water-tight connection. As its name indicates, the **soft solder** used has a much lower strength than that of the metals to be joined; thus, to increase the strength of the joint, the surface of contact must be increased so that firmness is obtained by adhesion. The melting point of the solder must necessarily be lower than that of the metals to be joined. The joint, therefore, cannot withstand any great amount of heat, neither can it undergo any serious strain. To overcome the latter, the process of grooving has been adopted. This consists in grooving the edges from ¼ inch to ⅜ inch, adjusting them so that they clasp one another and closing with a hammer or machine. Soldering the joint concludes the operation.

A flux is always necessary to clean the joint and to prevent the forming or bring about the removal of any oxide that materializes during the process of soldering.

Riveting.

Another common method of making a metallic joint is that of riveting. This applies to thicker plates than those to which soldering can be applied. Riveting will, we believe, be used very widely for a long time to come. It offers a resistance which depends either on the adhesion of the overlapping plates or upon the rivets themselves, which act as a link. A good adhesion is not obtained unless the rivets are heated. The strength of a riveted joint depends upon the nature of joint—that is, whether it be a **butt** or a **lap** joint, and whether it is single, double, or trehle riveted.

Brazing.

A further method of making a metallic joint is that of brazing. This can be readily called **hard soldering** It is characterized by the use of a metallic cement melting at a high temperature and possessing a high mechanical resistance. It is necessary to heat the edges to be joined to a very high temperature, and to use a cleaning flux, which also requires a high temperature to melt it. Brazing is an operation which calls for more or less skill, because of the high temperatures involved. A forge or blow pipe is necessary to the operation. The use of the forge is rather costly, and not very convenient; while the blow pipe requires great skill in manipulation, because the localization of the heat tends to burn the metal, especially in the case of brass.

Welding at the Forge.

Next we come to welding at the forge. This method, as before noted, is only applied to iron and steel. The joint is obtained by energetic hammering of two pieces together, which have previously been raised to the welding heat. The great difficulty here is in the exact appreciation at a glance of the welding temperature. The success of the fire weld depends on the exact external observation of temperature and the state of the surfaces to the united, because all interposition of slag or oxide hinder complete welding.

Electric Welding.

Another method that has been used extensively for over thirty years is that of electric welding. In many departments of work this application has become very useful indeed. It is generally confined, however, to special industries, such as the manufacture of thin plate utensils, chains, etc.

Other methods used are the thermit process and various forms of blow pipe welding. The blow pipe processes embrace the oxy-hydrogen and oxy-acetylene methods.

Meaning of Autogenous Welding.

Before going further, perhaps it will be best to explain the meaning of autogenous welding. It is a weld that is accomplished without the interposition of a metallic cement whose properties differ from that of the metals joined. Nearly all the processes mentioned here have their own limited field of usefulness, or else possess some great drawback. The oxy-acetylene process perhaps possesses the most general field of application. This process, however, has only become commercially practicable since methods have been discovered by which oxygen can be manufactured in large quantities and cheaply. It is interesting to note that oxygen is of all bodies the most widely distributed in nature. It exists in a state of mixture in the air, one-fifth of the volume of the latter being oxygen. Water is a chemical compound of oxygen and hydrogen, about one-third by volume being credited to the former. Thus, vast natural supplies of oxygen have been provided by nature.

The most widely known characteristic of oxygen is its property as a combustion agent. In oxy-acetylene welding the acetylene is burned in conjunction with pure oxygen. Acetylene is a highly inflammable gas even in ordinary air, thus when it is mixed with oxygen in the blow-pipe and ignited the combustion occurs in a most vigorous manner, and the heat generated is most intense. It will be seen, therefore, what a direct bearing the economical manufacture of oxygen in commercial quantities has had upon the oxy-acetylene business.

Obtaining Oxygen.

From water, oxygen has been obtained commercially by a process known as electrolysis. This process, described briefly, is the passing of an electric current through the water, breaking it up into its elements, hydrogen and oxygen. These gases are collected in separate vessels, oxygen rising from the negative pole and hydrogen from the positive pole. Another method of obtaining oxy-

* The First of a series.

gen from Nature's great storehouse is by the manufacture of liquid air. The air is taken from the atmosphere and then compressed. It is then cooled to a low temperature and allowed to expand; thus a very low temperature is obtained which causes the air to become liquid. The nitrogen and oxygen of the air seem to become liquid simultaneously, but the first jet of liquid air is rich in oxygen and the nitrogen is removed little by little by a process of rectification. By the fractional distillation of liquid air the oxygen has also been obtained. The oxygen thus manufactured is compressed to about 150 atmospheres and stored in small steel tanks holding about 125 cu. ft. of air. These small tanks are the form in which the oxygen is marketed commercially.

Acetylene.

Acetylene, the other gas used in the process, is a compound of hydrogen and carbon. This gas is obtained from calcium carbide. When water comes in contact with calcium carbide, acetylene is given off and a white residue of the lime remains. Carbide of calcium is made in large quantities by fusing a mixture of lime with either coke or anthracite in an electric furnace. However, to return to acetylene, it is obtained from generators in which the calcium carbide is treated with water. Under ordinary conditions, acetylene cannot be compressed, because under pressure it becomes a dangerous explosive. It is, however, extremely soluble in a liquid known as acetone. When dissolved in this liquid it is not explosive under pressure.

The most general method of storing acetylene is by the following method. Cylinders are filled with a porous material which is saturated with acetone, and the gas is compressed into these cylinders up to pressures as high as 250 pounds with absolute safety. Cylinders containing acetylene are made in various sizes and are on sale almost everywhere. However, in most oxy-acetylene welding outfit a generator is employed. High pressure generators deliver the gas at a pressure up to 15 pounds, while low-pressure generators deliver it at a pressure from 3 to 5 pounds. The oxygen is also used under pressure, and this secures a sufficient velocity at the outlet of the blow-pipe, which is essential to prevent back-firing. Various forms of blow-pipes have been designed, and are at present on the market. There are many which have good points and there are again a number from which results would only be fair.

The Practical Side.

With this more or less technical description of the theoretical side of the welding science, we arrive at the practical side. It must, however, be understood that to get good results from oxy-acetylene welding, and to be able to always get these results, the welder must combine a thorough knowledge of the scientific and theoretical side as well as an excellent practical knowledge of the art. The greatest trouble lies in the fact that it looks so easy. A beginner with a few days' practice, and sometimes after a few hours' practice, can make really good looking welds, yet only by close attention to the theoretical as well as the practical side, can one expect to become really expert.

The Expansion Feature.

The pieces to be welded should always be clean and should be placed in position rigidly so that they cannot move during the welding process. However, they should not be so secure that the expansion caused by the heat from the blow-pipe is resisted. The factor of expansion should always be closely considered, and where the internal strains set up by the local application of the heat will tend to do serious injury to the casting to be welded, means should be taken to counteract and overcome same. Various methods have been devised to eliminate these strains, such as the heating to a high temperature of the whole piece, a part only of which is to be welded.

Weld Strength.

Some of the factors entering into the welding process which tend to lessen the strength of the weld should be studied and thoroughly understood by the operator of the torch. The largest field of application of this science is naturally that of iron and steel. It is a well-known fact that steel varies but slightly from iron in its chemical composition, and various properties can be added to or taken from, steel by heat treatment. The introduction or removal of very small quantities of carbon create great changes in the physical properties of steel, while the interpostion of a small amount of oxide which is readily formed at high temperatures, causes the bond to be weakened more or less. These conditions have to be studied closely and thoroughly understood. By so doing, the bad effects can be overcome and the weld be made autogenous. Furthermore, a great deal of care must be taken in choosing the welding rod. For iron and mild steels, the rod should be of soft iron and as far as possible Swedish iron of the first quality.

The problems which face the welder are not really as serious as they would seem, because the causes and methods of overcoming them have been carefully investigated and very simple antidotes have been discovered. Thus the process is destined to become one of the greatest importance.

U. S. PIG IRON OUTPUT.

MANUFACTURERS' statistics of the pig iron output of the United States for the half year ending June 30, 1914, have recently become available.

The production of all kinds of pig iron in the United States in the first half of 1914 amounted to 12,536,094 gross tons, against 14,477,550 tons in the last half of 1913, a decrease of 1,941,456 tons, or over 13.4 per cent. In the first half of 1913 the output was 16,488,602 tons. Comparing the output in the first half of 1914 with the output in the first half of 1913, there shows a decrease of 3,952,508 tons, or over 23.9 per cent. A few thousand tons of ferro-phosphorus, ferro-titanium, ferro-vanadium and other ferro-alloys are included for each of the half years.

The maximum production of pig iron in any two half-yearly periods was reached in the 12 months from July 1, 1912, to June 30, 1913, when the output amounted to 32,143,265 tons. The next largest output was in the 12 months of 1913, when 30,966,152 tons were made.

On June 30, 1914, there were three furnaces in course of erection and 13 were being rebuilt. Of the furnaces building, one was in Pennsylvania and two were in Minnesota. When completed, all will use coke for fuel. They will have a total annual capacity of 505,000 gross tons of pig iron. No new furnaces were built during the first half of 1914, but on June 30 a number of stacks were projected.

During the first half of 1914 there were five blast furnaces abandoned or dismantled, with a total annual capacity of 200,500 gross tons, as follows:—New Jersey, one, with an annual capacity of 60,000 tons; Pennsylvania, two, with an annual capacity of 120,000 tons; Virginia, one, with an annual capacity of 2,500 tons, and Michigan, one, with an annual capacity of 18,000 tons. Some of these furnaces had been idle for years.

Testing Crank Axles for Defects.—Kerosene is used in many European railroad shops for testing crank axles of locomotives, the process being extremely simple. Upon an engine being put into the shop for general repairs, the crank axles are thoroughly cleaned from grease and oil and given a bath of kerosene, after which they are wiped dry with clean waste or rags. Two pairs of wheels are then placed some little distance apart on a track, and rolled toward each other at moderate speed. The shock experienced when they come together forces out small particles of kerosene which may be secreted in minute cracks formed by crystallization or otherwise. Inspection after the impact

PROGRESS IN NEW EQUIPMENT

A Record of New and Improved Machinery and Accessories for the Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

DUPLEX CONTROL HORIZONTAL BORER, DRILLER AND MILLER.

PRIOR to 1850 the boring of small holes was done under the drill press, or in the lathe when great accuracy was required. For work that could be handled on either of these machines, the usual method was to employ the portable boring bar with a traveling head and star feed. All of these methods were more or less slow and cumbersome. In 1854, Bement brought out a horizontal borer with spindle at a fixed height and a vertically adjustable work table. On account of great adaptability, together with the convenience of being able to operate it from either side, this machine has continued in popularity to the present day. In 1875, the Bement Co. made another advance in boring machine design by building a new type of horizontal borer. This machine had a stationary post with a vertically adjustable saddle, the table being at a fixed height and provided with cross and longitudinal traverse. An adjustable outer bearing was furnished for support of the boring bar. Since that time a large number of machines of this type and similar in design have been placed on the market. The serious defect of being controlled from one side only is generally apparent.

Realizing the importance of duplex control on machines of this class, the Niles-Bement-Pond Co. is now manufacturing the improved horizontal borer, driller and miller illustrated herewith. This machine is of the elevating spindle type, but is symmetrical throughout with respect to the spindle axis, permitting the operator to stand on either side and have all the controlling levers within convenient reach. It is adapted for work requiring great accuracy and at the same time is designed for heavy boring. Service and durability are prominent features, the entire design being free from delicate parts.

Perhaps the most striking feature of the design is the location of the spindle saddle within the post. This makes possible the symmetrical construction about the spindle axis which has been carried throughout the design of spindle post, bed, tables and control—an arrangement very essential on a large part of boring work. This design also affords most rigid support for the spindle. The thrust is taken on two tracks, one on either side of spindle, eliminating entirely the possibility of distorting strains.

The spindle is of the best quality high carbon, hammered steel, and is lapp-ground with great care. It slides in a long sleeve, which revolves in removable bearings, the main bearing being tapered so that adjustment can be made for wear. The spindle is driven through two large spline keys set into the sleeve and engaging with keyways in the spindle. It is fed and rapidly traversed by means of a screw in the saddle horn.

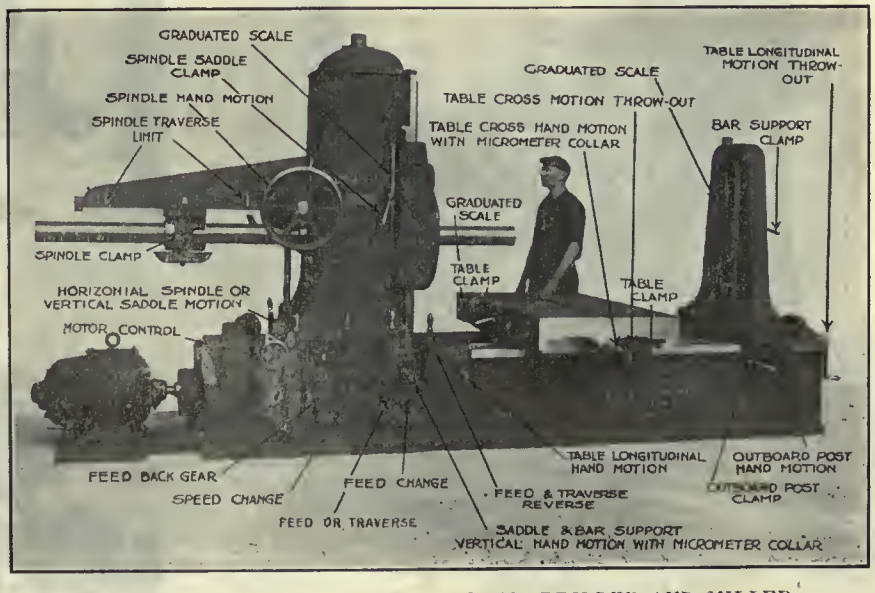
The front portion of the spindle has long bearings on V tracks planed on the faces of the column. The V bearings form the best possible method of preserving spindle alignment when the saddle is clamped for boring or sliding vertically for milling. Furthermore, with this construction, the hard back pressure due to boring adds to the truth of alignment instead of distorting the whole post structure. The saddle has vertical power feed for milling and also rapid power traverse. This motion is transmitted through a vertical screw, which is connected by gearing to a similar screw in the outboard post, so that the spindle saddle and outer bearing always move in unison. The spindle driving gear is enclosed within the saddle, with a portion extending outward and exposed for use as a face plate.

The spindle column is of box form, open through the centre, but connected at the bottom in one continuous casting. The column is held at the top by a cap tongued and grooved to it, the whole design making a very rigid structure. It is strengthened inside by ribs located in the best possible manner for resisting backward and torsional strains.

The saddle traverse has V tracks planed on the front of the column. The tracks have unequal sides; the faces toward the outside of the column are broad for presenting a liberal bearing surface for the saddle, while the faces toward the inside are at approximately right angles to the others for resisting side thrusts.

The outboard column is made in two parts. The lower portion is adjustable along the bed, and is gibbed thereto; while the upper part is bolted and doweled to the lower, so that it may be removed for long pieces of work and easily replaced in correct alignment. Provision is made for disconnecting the vertical lifting screw from the balance of the mechanism in order to avoid dismantling any of the gearing when the post is removed.

The table has a very large working surface with tee-slots for holding work. It is gibbed to a saddle with square locks having adjustment for wear. The table is provided with power cross feeds for milling and rapid power traverse for quick adjustment. It slides on a broad saddle long enough for support at the extreme position of its travel. The table saddle is adjustable along the bed by hand or by power through a screw running through the centre between the tracks of the bed. It is gibbed to the bed with square locks having adjustment for wear.



DUPLEX CONTROL HORIZONTAL BORER, DRILLER AND MILLER.

Power feeds are provided as follows: Horizontal feed of the spindle, suitable for boring and drilling; vertical feed of the spindle saddle and cross feed of the table for milling. In addition, automatic feed may be provided for circular motion of standard table, or in connection with a round table, if ordered. Feed screws are accurately cut and of large diameter. All feeds are reversible, and can be varied through the entire range for each spindle speed. The feeds are not affected in amount per revolution, as the spindle speed is changed.

The bed is a cored-out box casting, unusually wide at the top, presenting a liberal surface for table saddle bearing. It has broad flanges inside with fresupport, and is braced inside with frequent cross ribs. It is entirely closed at the top to prevent chips from falling inside. Within are the driving, feed and traverse gears. The driving gears run in an oil bath and the feed and traverse gears are lubricated by the splash system. The gearing is readily accessible for examination by removal of large cover plates on both sides of bed. The bed has been designed to give maximum strength and rigidity so that the machine can be placed where no special foundation is available. If ordered, a facing head will be furnished, which may be either attached to face plate gear or fastened on the boring bar. It is provided with automatic radial feeds by adjustable fingers and star. Also, if required, an additional work support can be supplied, consisting of a comparatively narrow casting, which extends across the bed and has adjustment on same. It is of the same height as the regular work table, and has a tee slot in the top surface for clamping.

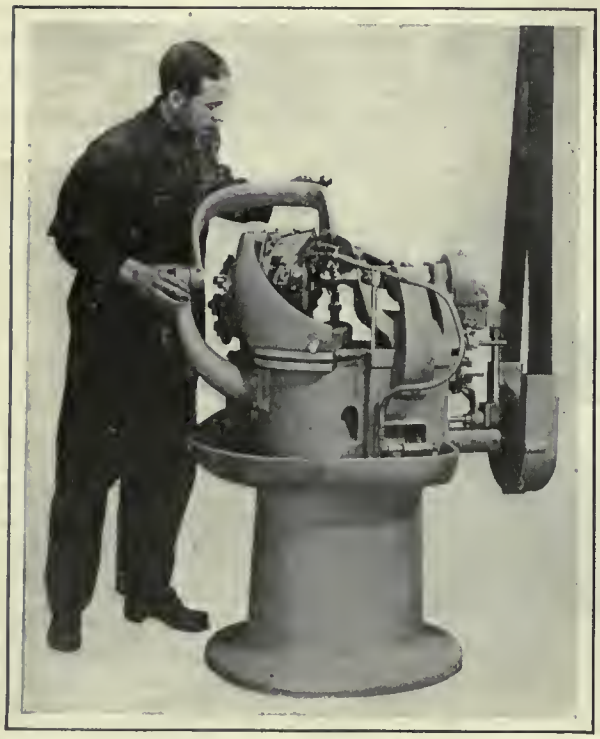
The drive is preferably by direct current variable speed motor of three to one range. The machine may also, however, be furnished with the following drives:—Cone and counter, single pulley through speed box, multi-speed alternating current motor, and constant speed alternating current through speed box. Inasmuch as the single pulley and constant speed a.c. motor drives require additional gearing, one of the other methods is recommended.

SMALL BEVEL GEAR GENERATING MACHINE.

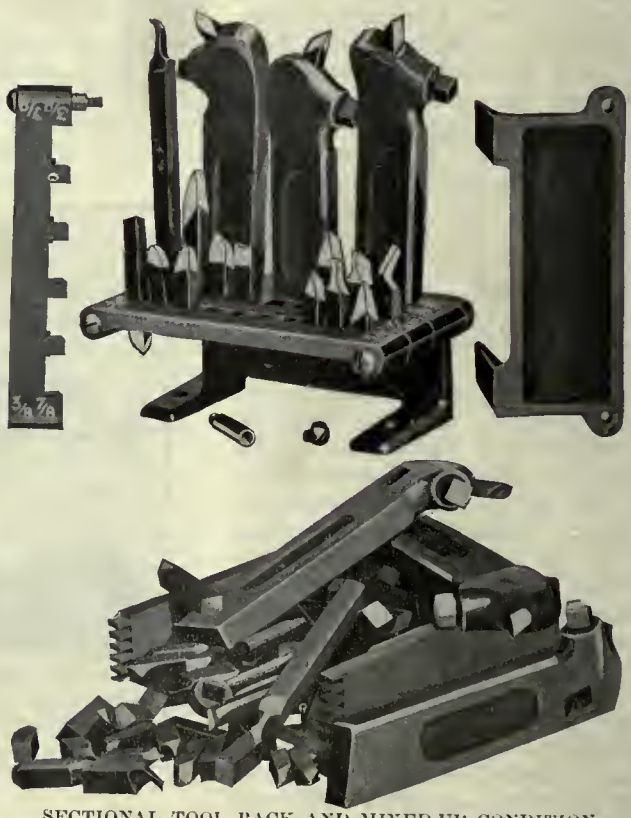
A SMALL size generating bevel gear planing machine has been developed by the Gleason Works, Rochester, N.Y. It follows generally the construction of the builder's line of two-tool gear generating machines, but is intended for making smaller bevel gears of the finest pitches. It is mounted on a pedestal integral with an oil pan, and there are a number of new features incorporated to facilitate rapid changing of the work. The machine will handle any bevel gear having a cone distance of not less than 2⅛ in. and a ¾-in. face. The largest pitch recommended is 8 diametral, and the smallest for which the tools are made as standard is 32. It is possible to cut smaller pitches, but the extent to which this can be done is limited by the fact that the tool must have sufficient thickness at the point to stand up to the cut.

A rack and pinion with a lever and a micrometer stop is supplied for shifting the head to any desired distance from the cone centre of the machine. When the distance from the apex of the gear to the back of the hub is known, it is simply necessary to set the micrometer stop to this distance, and then bring the head up to the stop, the locking being accomplished by a single lever. The use of tool gauges is simplified considerably by a limit gauge which is 0.005 in. over and under the desired length, with a separate gauge for the pressure angle. The machine will generate a tooth in 4 sec. as a minimum and 40 sec. as a maximum. The extremes of tool speed are 400 and 120 stroke per min., and a slip gear arrangement is provided for throwing the tools out of gear while making changes.

The indexing mechanism, which is positive in action, runs in an oil bath, as does the feed mechanism. Square gibs are used for all of the wearing surfaces and the shaft bearings have bronze linings. The net weight of the machine is 1,250 lbs. and a floor space of 32 x 44 in. is required. An oil pump for flooding the work while the cut is being taken



SMALL BEVEL GEAR GENERATING MACHINE.



SECTIONAL TOOL RACK AND MIXED-UP CONDITION OF TOOLS.

SECTIONAL TOOL RACK

THE purpose of the rack to which our illustration and description refer is to furnish the means for keeping the tools shown in a systematic manner, a great many holders and a great deal of expensive steel and time being lost looking for these tools, for the reason that there is generally no way provided to take care of them when not in use.

The rack is made sectional, all sections being interchangeable, this feature making it possible to assemble racks to hold tools for different size or sizes of holders or steel. Each section is made to hold tools of only one size, and it is so constructed that no other size can be put into it, because a smaller tool will fall through, and a section will not hold a tool that is too large. For this reason tools are automatically assorted as to their size; being put in the rack with the cutting ends up, so that it can be seen at a glance whether a tool of the size wanted is ground to the shape required.

The racks are designed so they can stand on tool boards, be fastened to side walls, posts, or any convenient place on the machines to be equipped with them.

C. H. Driver, Racine, Wis., is putting these tool racks on the market, and we understand his success has been such as to warrant his equipping an extensive plant to meet the demand that has accrued.

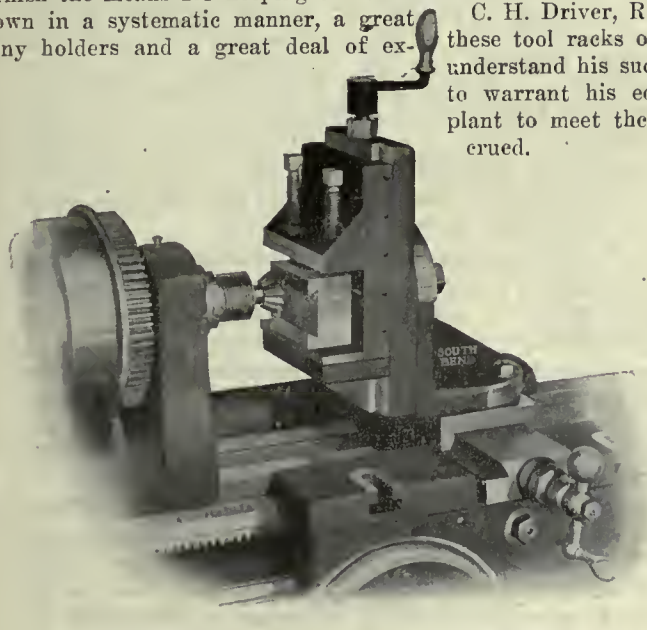


FIG. 1. ATTACHMENT FITTED TO LATHE.

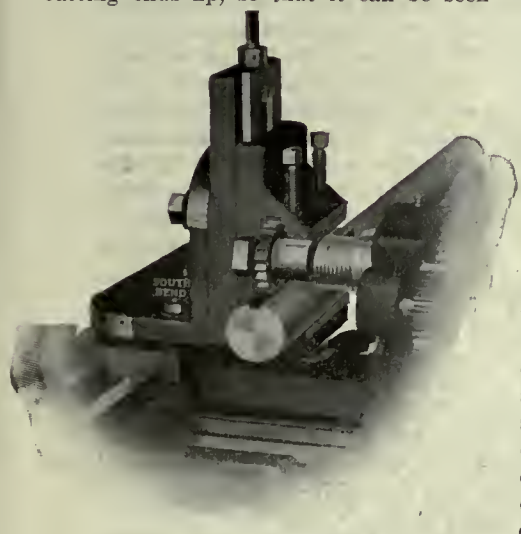

FIG. 2. MILLING A KEYWAY.

MILLING AND KEYWAY CUTTING ATTACHMENT.

THE milling and keyway cutting attachment described and illustrated on this page is a product of the South Bend Machine Tool Co., South Bend, Ind.; the decision to market it being the result of proven handiness and utility on lathes so equipped in their own shop. It enables a great deal of work to be performed on the lathe that otherwise would call for the use of a shaper or milling machine. The four illustrations shown represent what is known as the No. 3 attachment, as used on four different jobs. It fits on top of compound rest base, being located by a centre pin on base, fastened with two bolts and adjusted exactly like the compound rest.

The depth of cut is controlled by the feed of the carriage, the length by the cross feed screw, and the graduated screw at the top takes care of the vertical motion. The attachment swivels all the way around like the compound rest and is graduated in degrees. In addition, it swivels on the upright angle plate 180 degrees and is graduated. There is a graduated collar on the vertical screw, reading in one-thousandths of an inch. The attachment, although designed primarily for South Bend lathes, can be fitted by a mechanic to lathes of other makes which are equipped with compound rest. The regular equipment consists of milling attachment, two steel V blocks, one crank handle, one double end wrench, and two bolts and nuts for attaching.

Fig. 1 shows the milling and keyway cutting attachment No. 3 fitted to a No. 34-13 ins. South Bend lathe.

Fig. 2—View from back of lathe showing a ⅜ ins. keyway being milled in a 2-inch shaft. When shafts are taper where the keyway is to be milled, the vertical is simply swivelled to the desired angle.

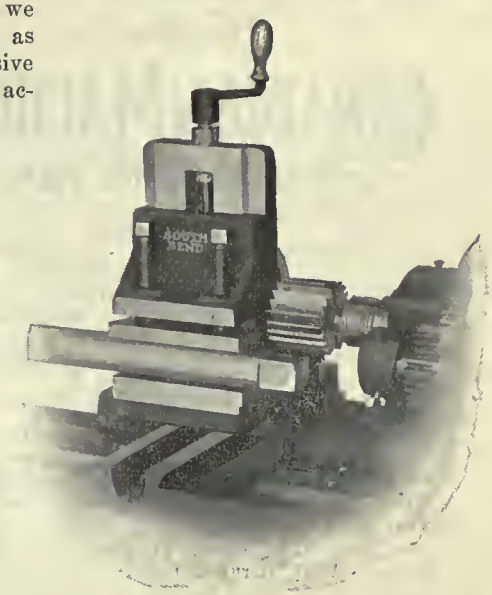

FIG. 3. SQUARING A STEEL SHAFT.

Fig. 3 shows a steel shaft being squared by milling. The shaft is held in the vise with V blocks, and can also be milled square by turning the attachment at right angles and feeding the shaft under the face of the cutter, or by feeding the shaft across the end of the cutter.

Fig. 4 shows the milling attachment holding a shaft which is being key-seated for the Woodruff system of keying. The cutter is held in a special drilling chuck, which screws on the nose of lathe spindle.

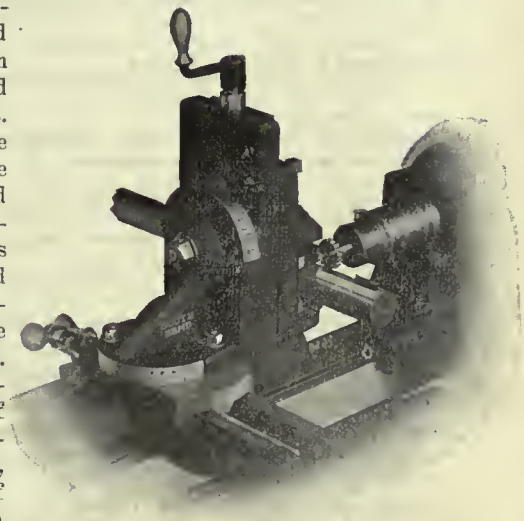

FIG. 4. MILLING A KEYWAY (WOODRUFF SYSTEM).

YOUR COUNTRY'S CALL.

NO apology is needed at this juncture for our drawing attention in the columns of this journal to the fact that the Dominion of Canada has issued a call, now in effect and remaining so long as the Empire to which we belong has need, for men. What are we doing about it? Indisputably we are loyal, yes, and as the past two weeks have shown, we have been supremely generous. The evidences of loyalty have been so satisfactory as to be unquestionably permanent; the responses expressive of our substance have met the meantime need; but the call for men—you and I, has only been in part met. Some 25,000 or 30,000 out of several hundred thousand available and eligible is what the hand of the clock registers, and a conservative estimate places Canada's requirement and her Government's desire to meet the Imperial situation at four times these figures .

Sir John Gibson, Lieutenant-Governor of Ontario, in the course of a patriotic address preceding the ceremonial of opening the 1914 Canadian National Exhibition at Toronto on Monday of this week, said:

"The fate of our Empire is trembling in the balance. More men must be sent from Canada than the present contingent. Another contingent of 25,000 or 30,000 men must go and still yet another. Canada can send 100,000 men if necessary to fight for the Empire.

"The young manhood of Canada is on its trial. Those who have gone were largely Canadians of adoption only. Shall it be said that there is any backwardness on the part of our native young Canadians in fighting for the Empire. We have sung our loyalty in various anthems from the cradle. Shall there now be any hesitancy among our men in backing their words with actions?"

His Honor impressed firmly upon the audience his belief that Canada must yet do her full share in supporting Great Britain, and further expressed the hope that as our contingents go to the front there shall be a flocking of young Canadians to fill up the vacancies left in the militia. Every young man between the ages of 18 and 30 years should step into the ranks and learn to march, drill, and above all to shoot. They may not be called upon to put the knowledge that they acquire thus into service, but they may rest assured that by such action they are adding their mite to the protection of the Empire and incidentally building up a healthy Canadian manhood.

In view of the foregoing but more especially on account of the circumstances with which we are at least conversant if somewhat indifferent, isn't it about time that many of us between the ages named and upwardly beyond **took the shilling.** Mollycoddles we make bold to say are a small percentage of our male citizens, and after all they can be spared; in any case, nobody need continue to be one of the class. Canadian business enterprise is not going to be blotted out, although 100,000 of our able-bodied manhood take the field. There will be abundance of mature minds left to care for that, and plenty of able-bodied help as well. Don't rely, however, on the other fellow enlisting so that you escape the **Call of Empire.**

The appeal for the military and naval services of Canada's manhood is unique, both on account of the issues involved and of its fortunate rareness; the response should therefore be all the more hearty. Do we realize sufficiently, and do we read into the dispatches from the front that citizens of the British Empire like ourselves are lying in the trenches holding back a powerful enemy, and one whose aim is to snuff all of us out completely. At the desk, in the store, on the street, at the bench and in the factory, 100,000 men can easily be spared, and at the front there will easily be found room for them.

Don't leave it to little Belgium, France and the British Isles to roll up the enemy's attack, and don't wait till Russia gets up to the gates of Berlin, but be one of a Canadian host ready to stand shoulder to shoulder with all of them in their combination effort.

CANADIAN MANUFACTURERS AND THEIR OPPORTUNITIES.

OUR newspapers for dearth of real, live copy from the firing line have not been remiss in their efforts to keep us posted on what has transpired and is transpiring behind the scenes, so to speak. Voyagers on the Atlantic, real and imaginary during the last few weeks have been made to go the limit in the attempt to magnify the discomfiture, we had almost said hardships, they had suffered because paint of a sombre hue had given place to the smart color scheme on many of our liners, and because all lights were blanketed, except those needful for navigation. Hysterical women and scare-beckoning men have been commandeered to fill the breach which a rigid censorship of real news has uncovered, hence, as nature abhors a vacuum, the extravagant activity of distorted imaginings in the simple practice of safety first under somewhat abnormal circumstances. It is not our purpose to enlarge on the foregoing, neither are we finding serious fault with our contemporaries, the newspapers, although we would advise the poor beings who have had their senses shocked by the harrowing experiences they are reckoned to have undergone to stow themselves a few thousand miles further away from the army and navy of Germany, so that their excitement gets a chance to cool off.

What we are concerned with, however, is the sombre hue which our Canadian factories have assumed, and the wholesale blanketing of their lights that has taken place. It appears as though some of these phantom German cruisers that roamed the broad Atlantic and Pacific Oceans had captured the trade of Canadian manufacturers, destroyed their wireless, figuratively speaking, carried off their bank accounts, locked the factory doors and forwarded the keys as trophies of war to Berlin. In a word they have ceased to do business in the open, with the result that nobody knows whether they are dead or alive. Micawberlike, they are waiting until something turns up. As a contemporary very pointedly remarks, they have run to cover after phoning, wiring and writing all with whom they do business, to stop everything. They have recklessly suppressed their business campaigns in their every aspect, and it calls for neither great display of intelligence nor deep reasoning to warrant the conclusion that in normal times they most probably follow the same reckless, unsystematic plan of business conduct.

That our industrial managements should have unlimited confidence in the ultimate success of the Allies, and in the future prosperity of this Dominion, is good advice to give as far as it goes, and God knows, in this respect, no slackness has been apparent in both drumming and rubbing it in, so much so, that we are afraid it has lulled many to sleep, who awaken only to eat. Our business men don't need to be told to have confidence, unless it be in themselves, for they have it to the full we believe in both our Empire and this Canada of ours. What they want is courage and that not when in crowds or associations, but real, personal, individual courage. If an individual lack confidence in himself, then he lacks ability in whatever his sphere, and little courage as a consequence may be expected. Where then do our Canadian business men stand relative to their business capacity?

Opportunities by the score are being dangled before our captains of industry due to the export markets and home industries of the active belligerents having become a dead letter. What real effort are they making to grasp these opportunities, for they won't materialize without effort?

There is a disposition to treat the trade possibilities as so many fairy tales, assuring ourselves that there is nothing to them. Yes, we seem determined to wait till someone hands us our portion. Our attitude towards the business opportunities which have materialized is essentially wrong. We neglect the all-important fact that there is a time limit set on these, and that it will require both courage and energy on the part of all who would secure a share. Don't let us run away with the idea that this North American Continent has everything coming to it on account of the European War. Far be it, for although the balance of opportunity be meantime in our favor, enabling us to get a new and at the same time firm foothold, the opportunity will pass when, the belligerents with their craving for human blood sated, betake themselves again to the practice of the arts, crafts and manufactures. The ravages of war and the retrogression so evident in the industrial and commercial life of the world, on that account, will certainly be compensated for in determined, consistent, double-barrelled effort to regain whatever loss of trade prestige has resulted, and just on this account something more than a finger-and-toe hold on business meantime going a-begging, will be absolutely essential.

A PRACTICAL SHOP ECONOMY.

IN the great majority of Canadian industrial concerns, attention is given to the home production of much of the plant equipment. Standard machines are built today upon which it is possible to carry out the greater part of every manufacturing process, and most of these can be readily procured from stock and some at fairly reasonable prices. The usual practice is to buy the best standard or universal machine to perform the desired work and secure the greatest economy from this by making and attaching suitable jigs and fixtures. These attachments are, however, often cumbersome and heavy and impose more or less dead load on the machine which it was not intended to carry and which, as likely as not, catches its weak spot.

The building of such attachments is more or less costly, and if the expense thus incurred be added to the original price of the machine, the final statement will show an apparently excessive investment of capital. A very much more satisfactory way from every point of view is to build machines at home especially suited to perform certain work as automatically as possible. Mechanics who can design and make fixtures adapted to the machine to which they are to be attached as well as to the best performance of the desired work, are fully competent to build a special machine to do the same work.

All standard machines, especially machine tools, are built with a view to strength and accuracy, coupled with a high degree of flexibility, all of which must be paid for whether the work demand these qualities or not. The special machine may be comparatively simple and often much smaller than the regular one which is still further increased in bulk by the necessary attachments. The principle can best be carried out by plants operating smith-shops and foundries as well as machine-shops in their regular course of manufacturing, but we have noted a number of successes, in the direction indicated, achieved by firms who have been obliged not only to purchase forgings and castings, but to have the patterns made out as well.

In order to manufacture goods to meet competition successfully, the use of special machines must be more generally adopted throughout Canada, and if this machinery can be made in the plant where its requirements are best known, there will undoubtedly be realized a considerable saving by the firm concerned. The first requisite is a man particularly suited to take charge of such work, the qualities of a practical genius being more to be looked for than high technical standing.

The General Market Conditions and Tendencies

This section sets forth the views and observations of men qualified to judge the outlook and with whom we are in close touch through provincial correspondents.

IMPROVED BUSINESS OUTLOOK.

A DECIDED improvement in the tone of business is now observable. Excitement has materially subsided and generally speaking, all concerned with trade and commerce appear to have settled down to the realization that the only way to defend their country and keep its flag flying is to attend to business in a normal way. If Canada is to maintain her troops at the front and otherwise do her share towards the defence of the Empire, it will be absolutely essential for those who are not handling arms to see to it that their hands are kept busy producing. This cannot be done by ignoring our liabilities and otherwise avoiding duty, using as an excuse for so doing the existence of war conditions very far removed from our own shores.

Adjustment to new conditions is taking place very rapidly. Many of our factories are moving as they have not done for some time. In one instance an agent representing a German house found himself without employment. He searched for a Canadian house handling a similar product, when he made application for permission to handle their products he found that its output had already been fully taken up. Other factories who have suddenly found their market cut off can either find a new market or adapt their plants to producing something for which there is a market. Our enquiries during the week lead us to the conclusion that some good work in this direction is being done.

Action of the Banks.

We have every reason to believe that the banks are treating their customers exactly in accordance with the lines of credit agreed upon. For ordinary current trade purposes they are not withholding credit and in some cases special consideration is shown. Treatment of this kind, however, cannot be expected by new customers. We are confident, however, that bank managers generally realize that they have an important duty to perform in assisting their customers to adjust themselves to conditions which were not foreseen, and they are doing everything it is possible for them to do.

Moving the Grain Crop.

Canada's foreign trade routes are now practically safe. It is fortunate, as we are on the eve of our big Western crop movement. Banks have extended to dealers in the West customary lines of credit. A week ago there was some doubt as to what course would be taken but during the week a change has taken place consequent upon the improvement in the situation in London and in regard to the control of the sea. It is being realized that whatever may be the fortunes of the allied forces in Europe there is no danger of Great Britain losing her ocean supremacy. This being the case there does not appear to be any reason why Canadian trade should not be maintained at practically normal. In some lines there will be stagnation, but on the other hand others will be exceedingly active. Let us again draw attention to the fact that the products of Canada in the main are necessities for which there is a greater and more pressing demand at the moment than there has been at any period in the history of Canada.

Montreal, August 31, 1914.—A week ago there seemed to be a prevailing feeling of confidence that once the allied armies of Britain and France were face to face with the forces of Germany that

the advancement of the latter would be finally checked. It is well known that there has been a battle, but the results have not been as decisive as were looked for. Thus confidence has suffered a little and we find that business has again lapsed into a state of uncertainty.

During the past week a few shipments of steel have arrived from British ports, and these have been of sufficient influence to keep the prices of steel almost the same as last week. The trade, however, has been so extremely dull that there is really no occasion to alter the prices.

Machine Tools.

In this line of business no change can be looked for until the war situation improves. Those who import their products from Britain and Europe cannot of course get delivery, but even were this possible, sales on any large scale are meanwhile doubtful.

Pig Iron.

The pig iron market is no exception to the general dullness. European shipments are again very uncertain. A large number of foundries are closed down, while those that are still operating are only doing so to about one-third to one-quarter capacity. Prices do not change appreciably.

The Steel Market.

The situation has not changed to any extent regarding the prices of steel. It is reported that the United States Steel Corporation have sent out one hundred and fifty new salesmen to try to obtain some of the trade previously held by German firms. It is also reported that British steel rolling mills are asking for prices on Canadian and American billets. These were previously supplied by German firms. Some of these enquiries have been directed to Canadian firms dealing in steel.

Machinery Supplies.

The firms dealing in these supplies are enjoying quite brisk business, although orders are small. The supply side of the larger houses dealing in machine tools helps to keep their organizations together, thereby enabling them to meet the increasing trade when it materializes.

Metals.

The metal market seems to end each week's business in much the same condition as it entered. Tin has taken another drop of five cents per pound, and spelter has risen slightly. Aside from these changes, the market remains as before. The New York and London Exchanges still remain closed, so quotations are more or less of a nominal nature.

Toronto, Ont., Sept. 1, 1914—The European war continues with unabated fury, and no engagement of a decisive nature has been recorded. Until such time as the allied forces make definite progress the present situation cannot be expected to improve to any marked degree. Business is still marking time, waiting for an improvement in the outlook, which we hope will not be long in coming, although present indications point to a longer period of suspense than was, perhaps, at first anticipated. As far as our overseas trade is concerned, we can look with the greatest satisfaction at the way in which the trade routes have been kept open by the British Navy. With reverse conditions, trade would have received a very serious setback; but as it is, shipping conditions are improving daily, and, except for a diminution in shipments, caused by the war, sailings would soon be back to former schedules. The effect on our import and export trade will in some respects probably be felt for some time.

A wonderful wave of patriotism has swept over the country, and it is to be hoped that the same spirit will animate the community in their business dealings, and so help the country during the crisis. It is absolutely necessary to keep the wheels of industry moving and maintain production at as high a level as possible, for by so doing the effect of the war will be minimized and prove less of a burden to the community. It requires courage and confidence in the future and often sacrifice, but the result offers full compensation. If the keen interest and enthusiasm which is apparent everywhere can be guided into the proper channels, much good will result.

Steel Market.

The iron and steel markets are very quiet, and comparatively little business is being done. An improvement can hardly be expected until more satisfactory news comes from Europe; even then it is possible that it will not greatly increase the amount of business for some time, but it will have a distinctly stimulating effect, and so pave the way to better conditions. The general situation is similar to last week; manufacturers have withdrawn prices, and are only quoting against definite inquiries and for immediate acceptance. Marine insurance and ocean freight rates are both above normal, which is having some effect on trade.

There is a feeling gaining ground that the steel trade in Canada will benefit by the war, on account of the production being checked in the European countries involved in the conflict. It is too early to state with any assurance that this will be the case, but an effort will no doubt be made to capture some of the foreign business. Whether this will be successful remains to be seen, but it is probable that little will be done in this direction until financial conditions improve and exchange becomes nearer to the normal; the latter feature is an important consideration.

Although only some lines have advanced in price, there is a tendency for an all-round increase, particularly in the United States, which will, of course, affect Canada. A number of small orders for plates are being placed with United States' mills, but the tonnage is not heavy, the price usually being $1.25 Pittsburgh, or 5 cents above the market. The ferro-manganese situation is a little easier on the strength of shipments expected this month from England. This alloy is quoted around $100 a ton tidewater, and will probably remain at this figure, or possibly be higher, for some months. Galvanized sheets and black sheets have advanced, but the prices are fluctuating considerably.

Pig Iron.

The pig iron market is dull, and there is little demand. Moderate lots of domestic iron are selling at former prices, but no English or Scotch iron is being imported at present, and little is coming from the United States. Consumers are buying very little iron for the time being, and many foundries are working at considerably reduced capacity.

Machine Tools.

Little business is being done in machine tools, and the situation is unchanged. At the local Exhibition all space has been taken, and it may help to stimulate inquiries, and, it is to be hoped, result in business.

Machinery Supplies.

Business in supplies is dull. A number of machine shops have either closed up or are running on short time, consequently the demand for supplies has fallen off. Prices generally are stationary, but a number of manufacturers have withdrawn prices, and will only quote against definite inquiries. Babbitt has advanced on account of the increase in price of metals. Magnolia, however, remains unchanged. Cast iron fittings have advanced, also domestic leather belting.

Tool Steel.

The tool steel situation remains unchanged. There is little demand on account of the machine shops being so quiet.

Metals.

The metal markets generally are still in an unsettled condition, although steadier than might be expected under the circumstances. The tin market is quiet, with little demand. The price is the same as last week, but will probably go higher, as no relief in the situation is in sight. Spelter is erratic, and has advanced slightly, being quoted at 6c. Copper is weaker, and antimony has dropped to 20c, although the situation has not changed as regards the latter. London and New York Metal Exchanges are closed indefinitely.

TRADE AND COMMERCE RECORD

Dealing With the Steps Being Taken and Progress Made by Industrial Canada To Achieve and Maintain a Dominant Place in the Markets of the World

THE WORLD WANTS OUR PRODUCTS.

By H. Waddington.*

THERE'S a lion in the way. Such was the theme of an old-fashioned Scottish divine, and the terrors that he could instil into the minds of his hearers were in every case overpowering.

Unfortunately we have some of the same type with us in the financial and commercial worlds of to-day. We have a lion ready to devastate our trade, to ruin our possibilities, and to use our old friend Mantalini's phrase, to send everything "to the demnition bow-wows." But,—where is the lion? Analysis shows us that he is behind us and not ahead. The Britisher is essentially a trader and the Anglo-Saxon is an assimilator. Beaten in war he sometimes has been; in the final result, however, he has been the victor not through force of arms, but by the process of assimilation. What do we produce that the world in general does not want? We have no factories turning out luxuries such as the wealthy only can purchase. We do not make gew-gaws such as people can do without. We do produce the necessities of life and the world must have them.

The British lion tells us that the trade routes are now open and perfectly safe and Europe wants our food stuffs.

The German manufacturer has been shut out completely from markets for all classes of its manufactured products, some of which we can supply. The morning press tells us that our High Commissioner Perley has sent some men over to find out what we can do to help out the British building trade. Germany has hitherto largely supplied wire nails and builder's hardware to Great Britain, and this has now been stopped. Here is our opportunity. Instead of shutting down our factories, we should run full steam ahead, as the market is waiting, and we should have the stock ready when the orders come. We may rest assured that our neighbors to the south will be keen to corral everything as far as they can. We should not lag.

The tremendous withdrawal of men from the factories in the old land must of necessity cut down their output, and where is this to be replaced? The opportunity is ours. Cut out the pessimism and take hold of the possibilities. We are furnishing some of our best in the form of manhood for the army. Let us give of our best in food stuffs and manufactured products.

The lion is in the way, but we are to ride his back and help him clear away the obstruction. We are **not** to be devoured.

Everything we have is and will be in demand, our foodstuffs, our manufactured products, our men, our moral force, our manhood. We are here to develop ourselves. Hitherto we have leaned on John Bull. We have now reached maturity. Let the position be reversed. Let him lean on us and lean heavily. We have what he wants; he is willing to pay and to pay well, and we should have the desire to show that we are fully capable of standing alone as far as our needs are concerned and of helping the other fellow when he needs us.

Keep the factories running. In a few months' time we shall not be able to cope with the demands.

*Managing Director, Standard Reliance Mortgage Corporation, Toronto.

INDUSTRIAL HYSTERIA.

CANADIANS are showing symptoms of an acute attack of economic neurasthenia. No one can accuse us of being afraid to fight. Show us a German and we will tackle him, without hesitation. What we are afraid to do is to go on living. Instead of composedly and cheerfully taking up each day a task as the day appears, we are trembling in anticipation of unimaginable scarcity and poverty. It is not hard times that we expect, we have them already. It is not simply hard times made harder by war. We could understand that and meet it. It is times so stark and inflexible that iron is in comparison as a sponge and the traditional poker pliant as a thread. More prosaically, it is something formless, vast and ghostly, the more dreadful because our reason gives it no shape. If we were all to be doomed to death by slow starvation we should scarcely be more frightened.

We may admit that the war will disturb trade, remove bread-winners from their homes, pile up private and public debts, and generally mitigate the prosperity of the recent past. It is well to be prudent, to eschew luxury, to avoid over-production, and to provide means for helping the specially unfortunate. Having said this, we have said it all. The sun will shine, the harvests will ripen, all the staple commodities will have to be produced, and there will be just as much food and money in Canada next February as there was last February.—Montreal Journal of Commerce.

OUR MANUFACTURERS WAKING UP.

A STEADY stream of callers as well as letters, telegrams and inquiries to the Department of Trade and Commerce indicate that Canadian manufacturers are awakening to the opportunities of trade development resulting from the war, and particularly to extend their activities to those lines heretofore imported from Germany. No less than a dozen firms had representatives at the Department last week-end securing information along these lines, and all of them are very hopeful of being able to keep their factories going at full capacity.

This would be not only to supply the Canadian trade, but to capture trade to countries such as South America, which are extensive patrons of German industry. Statements are now being prepared by the Department and will be sent out immediately they are ready. They will show the extent and character of all German imports to Canada and to other countries where the trade with Germany may possibly be secured by Canada.

It is confidently believed that a decided stimulus to Canadian industrial activity will result from this campaign, which is regarded as truly patriotic and in the best interests of the country.

A CALL FOR CONFIDENCE DISPLAY.

FITZ-JAMES E. BROWNE, the well-known real estate and property expert, Montreal, recently addressed letters to over 200 leading business men of that city, inviting them to hear his talk on **Confidence**, which was to be given in his auditorium on the day following. He said:—

Dear Sir,—Have confidence. A drop of water does not make a sea—a pebble a seashore, or one man a regiment; but it is the multiplication of the unit that evolves power and enables the wheels of industry, finance and commerce to revolve and hum freely. Because one man has a **swelled head** and thinks he ought to own this universe, is that any good reason why everything should come to a standstill?

It would seem as if for the time be-

ing the people have been carried away by a wave of fictitious imagination and have lost their usual business composure. It always takes a crank to start a scare of panic, which is generally short-lived with business once more reasserting itself. The present commercial situation is no exception.

To light a city you must dam a river at the right place and install your generative machinery, which makes the electricity that lights the city.

To enlighten the public we must build a dam of confidence to check the crazy ideas, notions and lies that have been spread broadcast during the past few weeks by the yellow sheets of journalism, install our machinery of common sense, and by it generate a power of good that will enlighten the people so they will have confidence in the outcome.

We appeal to you as one of those having unlimited confidence in the future of Canada, and more especially of this city, to co-operate with us in this movement of confidence by investing in real estate in this city, thus proving your confidence, which we know is not misplaced.

MANY TRADE OPPORTUNITIES PRESENTING THEMSELVES.

EVIDENCE has come before the Department of Trade and Commerce at Ottawa in the remarks of several United States publications to show that the people of that country are realizing the opportunity that is presented for enlarging their export trade, now that active competition in the world's markets on the part of several European countries has been withdrawn as a result of the present war.

"To a certain extent," says a bulletin issued by the Department, "the arguments put forth by these publications are applicable also to Canada, yet while it is generally pointed out that an extended European conflict will prove of great benefit to Canada as a supplier of foodstuffs, the opportunity given to Canadian manufacturers to develop their export trade, through the temporary withdrawal from the sphere of world trade of such countries as Germany and Austria-Hungary, does not appear to be generally realized."

Austrian and German Trade.

The bulletin, in dealing with trade opportunities open to Canada, states first, "as a result of the war, Canada's direct trade with Germany and Austria-Hungary must necessarily suffer. In 1913, Canada imported from Germany goods worth $14,473,833, and she exported to Germany goods to the value of $3,402.394, a total trade of $17,876,227. With Austria-Hungary, Canada carried on a total trade to the value of $1,829,943, of which $1,674,349 consisted of imports and $154,594 of exports. It is thus seen that these countries, especially the former, had obtained a foothold on the Canadian market which will be lost during the progress of the present war. An opportunity is presented for other countries to increase their trade with Canada or Canadian producers to make up a part of the deficiency thus created."

The foremost market of which Germany will be deprived as a result of the war is the United Kingdom, which has been buying goods from Germany at the rate of about $145,000,000 a year. Germany's exports of agricultural machinery to Great Britain in 1913 were $131,189, as compared with $437,090 from Canada, and of sewing machines $500,000, as compared with Canada's $2,263.

Big Machinery Trade.

Under the head of general machinery, Germany has exported to Great Britain to the value of over $5,000,000 a year; of electrical machinery, over $31,000,000 a year; of electrical goods and apparatus, $41,000,000 a year; hardware, $4,000,000; boots and shoes, $250,000; brooms and brushes, $789,000, as compared with an import from Canada of only $7,917; and of paper, $2,017,575, as compared with an import from Canada of $587,010.

Germany's trade with various British Dominions has also been large, and here also is an opportunity for Canadian manufacturers. Australia's purchases from Germany amount to over $32,000,000 a year, as compared with but $3,996,387 from Canada. South Africa imports $17,000,000 worth of German goods annually, as compared with less than $4,000,000 from Canada.

TESTING TIME NOW.

We must continue to live by satisfying each other's wants. The interruption of established trade routes necessitates the opening of new ones. Our captains of industry are now facing a real test of their ability.

U. S. RECEIVES HEAVY EXPORT INQUIRIES FROM BRITAIN.

A large English works has sent out an inquiry for 50,000 tons of billets, sheets, tubes, rounds and other forms of semi-finished materials, while another inquiry is for 10,000 tons of small billets for British Isles. This is different from the 10,000 tons for Glasgow, previously reported. Another lot of 1,500 to 2,000 tons of small billets is pending.

NO TIME TO "TAKE TO THE RAFTS."

MORTIMER B. DAVIS, president Imperial Tobacco Co. of Canada, when interviewed a few days ago, gave the following expression of opinion:

"At a time like this, financial institutions, railroads, manufacturers, jobbers and retailers should strain every effort to keep their men employed at regular wages, even if it is necessary to manufacture and carry in stock a little more than the usual requirements. If this were done by a fair proportion it would eliminate, to a great extent, one of the conditions that we are anticipating this winter, resulting from the great war—viz., the problem of the unemployed, and would stimulate business through the purchasing power of the public. The present is an opportune time for the country to do this for the reason that for the past eighteen months a great deal of liquidation in everything has taken place.

"The commercial result of the war must benefit the North American continent. Goods produced and manufactured in Europe must be replaced in the course of time by American and Canadian manufacturers, and it is an acknowledged fact that when conditions of trade are prosperous in the United States the same condition exists here. Furthermore, the farmers, the greater part of our population, are not affected; in fact, they are benefited owing to the higher prices they will receive for their farm products; it is the people in the cities and small towns, employed in factories, etc., who should be looked after.

"At a time like this, people whose incomes have not been affected should continue to spend as heretofore. It would not be wise for large sums of money to be invested in new enterprises with a prospective profit that takes time to materialize, but, where money can be spent in a commercial way with a reasonable certainty of bringing quick returns it should be done."

Welland, Ont.—The employees of the Page Hersey Iron, Tube & Lead Co., had an ideal day for their third annual picnic at Port Dalhousie on August 22. About 325 took in the outing from Welland and the whole of the main office force of Toronto.

Foundry Department, the Massey-Harris Co., Toronto, Ont.

Staff Article

While there are not a great many foundry establishments in Canada of the size of the one here described, very much can be learned by the smaller concerns of the benefits accruing from the encouragement of a flexible system in which harmony and thoroughness are given prominence. The choosing of a staff on points of merit, rigid economy, the application of the most suitable appliances and the appointment of the right man to each job are stepping stones in the rise to prominence of this world-known institution.

BY the courtesy of the Massey-Harris Co., of Toronto, through their general superintendent, R. H. Verity, we are enabled to present to our readers the story of one of the most advanced and up-to-date foundry establishments in Canada, and indeed, one that ranks among the best on this North American continent. We have also been favored with the assistance of W. J. Cornish, the foundry superintendent, and by the fact that the plant was shut down for annual stocktaking at the time the photos were made.

The aggressive policy of the company in securing markets in many different and widely distributed parts of the earth enables the plant to run at full capacity throughout the year except for stock-taking and repair periods. The sales periods of Europe, Australia, South America and other countries do not overlap to a very great extent, which fact, besides militating against the effects of hard times or loss of crops in any one locality, enables the designing and experimental departments to keep Massey-Harris implements fully up-to-date. The output of the firm is over fifty per cent. exported and their products have a good reputation in every country in which they are sold. As a consequence, the company has become not only one of the most stable enterprises at home, but is the greatest and most enterprising advertiser abroad of goods **Made in Canada.**

The product of the plant is such as to require a large number of small castings rather than a smaller number of heavy ones. This necessitates particular forms of moulding and handling practice which have been brought by long experience and a capable foundry staff to a high state of perfection. Implements, in spite of the fact that in the foundry a decidedly superior class of workmanship is required, must be sold cheaply and, in the case of this firm, mostly against a protective tariff rather than favored by one. This makes it absolutely essential to reduce the cost of production as much as possible, and the layout of the plant and purchase of equipment is planned with this end in view. Profits in this line accrue more from bulk than individual output.

The foundry proper consists of a main building 1000 feet long by 90 feet wide, extending along the south side of King street. At the eastern end are situated the tumbling barrels and cleaning rooms, and above these the pattern and equipment departments. In the middle of each of the two central sections are placed the cupolas and monorail distributing systems, which reach every part of the plant. At the western end is the core department, which with its mixing machinery and moulding machine storage, occupies three floors. The pig and scrap iron storage yards extend the whole length of the building on the south side. A basement 400 ft. by 90 ft., below the main building, provides for ample stor-

GENERAL VIEW OF PLANT FROM SOUTH SIDE SHOWING STOCK PILES.

age of coke, sand, clay and other supplies.

Moulding.

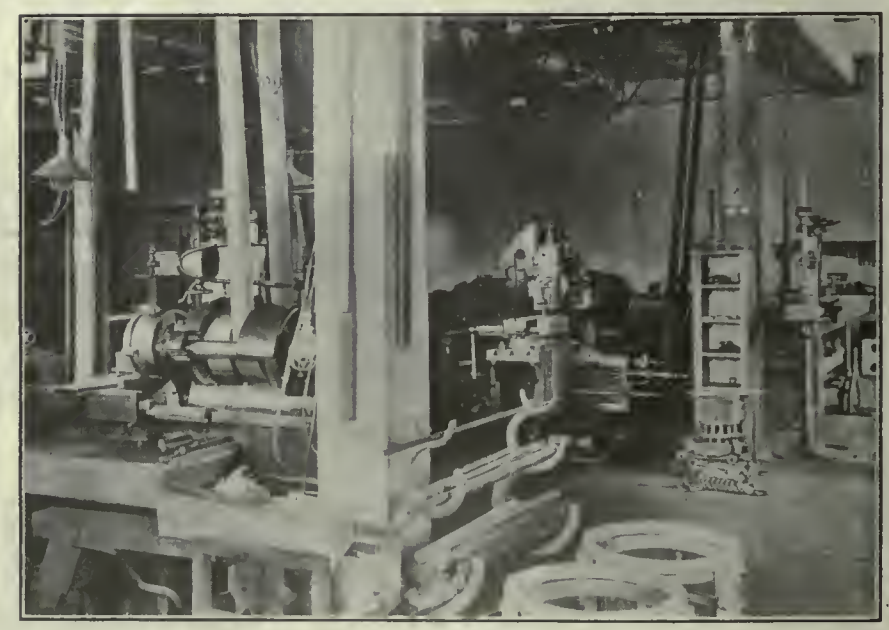
The manufacture of so much small stuff requires an exceptionally large floor area, and the saving of the moulder's time occupied in getting about his floor, to the greatest extent, has presented no small problem to the men in charge. This is accomplished to a certain extent in the case of the snap moulders by fitting the benches, with small wheels so that they can be moved back as the work progresses. Certain forms of moulding machines used have this advantage to an even greater degree, while in others, being necessarily stationary, this saving is not accomplished. The central part of the east wing is devoted to bench moulding almost entirely, multiple metal patterns and follow-boards being used. The central part of the west wing is given up to moulding machines of several kinds, the stripper plate type predominating. Along the walls in the bays for the entire length of both wings are located the air lines. All moulding machines requiring compressed air in any form, whether for moulding pressure, vibrators, air hoists, etc., are operated in the bays on both sides, giving the outer areas of the building a very animated appearance.

GENERAL VIEW OF EAST WING SHOWING RUNWAY.

Pattern Department.

As much as possible has been done to relieve laborious parts of the moulder's work. To this end, wherever practicable, the patterns are mounted on the various types of moulding machines. The pattern department, which may be either a great source of economy or by incapable supervision may be the cause of serious inefficiency, is under the care of a superintendent and foreman, both of long and trained experience in this class of work.

In conformity with the general policy of the company in manufacturing as much as possible of their machinery at home, not only patterns, but moulding machines, air hoists, flasks, and all other equipment, is built in this department. The question of the most suitable methods of arranging patterns is one that is given continual study, and is usually settled by the foundry superintendent, in conjunction with the general and pattern-room superintendents. The pattern department occupies a second floor space of about 5,000 sq. ft., and is provided with the best known appliances for the production of accurate duplicate patterns. These are made of brass, aluminum, iron, and various alloys, the material depending upon size, number required, shape and many other considerations. Patterns for implement parts, either of malleable or gray iron, do not constitute by any means, whole output, those for dies and special machinery for use in general manufacturing representing many tons of iron castings every year.



FRONT OR MACHINE SECTION—PATTERN DEPARTMENT.

Metal pattern-making involves a large amount of expert hand work, still a great number and variety of machines are used. These include several Fosdick radial drills, Canada Machinery Corporation 18-inch lathe, 26-inch double and 53-inch flat Gardiner disk grinders, Bertram 28-48-inch extension bed lathe, 18-inch American lathe, and others.

Pattern Storage.

A new pattern storage building has just been completed on the north side of King Street, and is connected to the foundry by a spacious tunnel. It is of thoroughly fireproof, reinforced concrete construction, four storeys high, and contains approximately 40,000 sq. ft. of floor space. Pressed steel shelving of the latest type, made by the Lyon Metallic Mfg. Co. of Aurora, Ill., is installed throughout, and light is provided by an unusual area of wire glass supported by steel sash. The vast number of patterns is so arranged and indexed that any desired piece can be located whether in the foundry or vault without loss of time.

Cupolas.

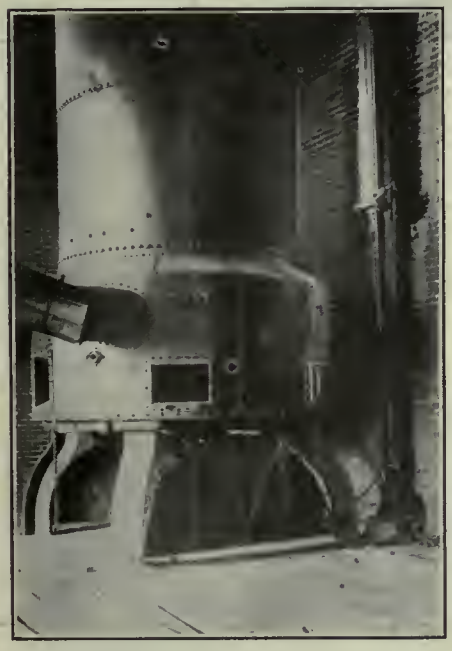
There are four melting furnaces, all built by the Whiting Foundry Equipment Co. They have 96-inch shells, and are lined to different diameters on the inside. Each has a capacity of 18 to 20 tons per hour, and the daily melt amounts to from 70 to 80 tons. The blast is furnished by a Roots blower directly connected to a 60 h.p. Lancashire alternating current motor. A stand-by auxiliary steam plant is always ready in case of accident to motor or failure of the electric current. The mixing and melting is in charge of an expert, who is provided with blast gauges and full

chemical information concerning all materials by the laboratory.

Laboratory.

The chemical and testing laboratory is a surprise in order and thoroughness, and the men in charge are under the direct supervision of the assistant general superintendent, who holds an important office in the Canadian Foundrymen's Association, as well as being high in technical standing. The chemistry department contains, besides a complete supply of reagents, titrating apparatus, fume cabinets, etc., also the most up-to-date electric equipment, including furnace pyrometers and the like. The main unit of the testing laboratory is a 75-ton Tinius Olsen tension and compression machine, with all automatic and recording attachments. There are also cross-breaking, percussion and other machines of the best types obtainable.

Three test bars are cast each day at critical points in the heat, and the results of complete physical and chemical tests are furnished the foundry superintendent for his accurate guidance. Also careful records are kept of each shipment of pig, coke and scrap which, along with experience of the melter, makes the obtaining of accurate iron mixtures practically possible. Not only does this system enable the Massy-Harris Co. to turn out castings of the greatest strength and most uniform quality, but all materials can be bought to specification, and that which is disqualified can be rejected. Poor material is thus kept out of stock entirely.



CUPOLA—BOTTOM DOWN.

Handling System.

The material transportation and cupola charging equipment is very complete. A narrow gauge industrial track with many branches and turntables, reaches every part of the iron storage yard. This is equipped with Whiting steel dump cars which, upon being loaded are weighed, raised to the charging floor and the contents automatically dumped by compressed air. An air hoist is also used for closing the bottom of the furnace when preparing for a heat.

Coke is received on the foundry siding direct from the ovens. The cars are dumped into a hopper beneath the track whence the coke is taken by a link-belt conveyor to the bins in the basement. From here it is raised as required by other conveyors to the charging floors, where it may be delivered to buggies, or convenient to shovel directly into the furnace. Complete conveyor systems are also provided for other materials such as sand, limestone, etc.

For the melted metal, a monorail distributing system is used which was designed and constructed in all its details by the plant engineers. From the overhead rail, pots holding 900 pounds of metal are hung by means of roller bearing trolleys, and so successful has been the designing that one man easily handles the gross weight of over half a ton. The pots deliver the melted metal to each man's floor, whence the pouring is done by the moulder himself with 60-lb. hand ladles. The tracks and switches are so arranged that the pots can return to the cupola by different routes and thus all interference is avoided.

TYPE OF SHELVING —PATTERN VAULT.

The Core Room.

The core department occupies the best

REAR OR BENCH SECTION—PATTERN DEPARTMENT.

part of three floors and is in charge of a specialist and assistant who are directly under the foundry superintendent. The core materials, like other stock, is stored in the basement. From here they are hoisted to the third floor by means of bucket conveyors, and are mixed by machinery in the various proportions required by different kinds of cores. From this floor the mixtures are delivered to the benches and machines on the second floor through chutes in the required quantities.

The systems of making cores are varied to suit the needs. Those of straight cylindrical form are made on a motor-driven Hammer rotary core machine of the Brown Specialty Co. which has been altered and improved to meet the demands of the plant. So-called flat-backed cores are made in multiple boxes on a Mumford Moulding Machine Co. core jolter which is operated by compressed air. The great quantity of irregular shaped cores are made by hand in iron boxes, which are made in multiple wherever possible. The benches are made almost entirely of metal, particular attention being given to the obtaining of a good smooth working surface. The aisles between the benches all lead to the ovens, which consist of 16 sections, each group of four being heated by a separate coke fire. The ovens are of the latest Whiting type supplied with adjustable shelves, sliding drawers, etc.

Ventilation, lighting and cleanliness have received a great deal of attention and all possible has been done in this way to make the working quarters in the often unpleasant core room agreeable to the men. A great help and time-saver is embodied in the core records. As many as possible are standardized and listed and up-to-date lists are furnished the core room, pattern and experimental departments, and all others connected in any way with the use of cores. Thus, the making of unnecessary and duplicate boxes is obviated.

CHARGING FLOOR—LOADED BUGGIES.

Brass Furnace.

For the melting and casting of brass, aluminum and alloys, a special floor is provided, which is equipped with a Monarch crude oil furnace having a capacity of 1,200 pounds per day. Another smaller furnace is used for melting the softer metals. These furnaces have been found to be very convenient and economical, and require little attention as compared with the old-style coke furnaces, and several heats can be taken off in a day if required.

Night Work.

When the moulds are poured, the moulder's day's work is done. Two night crews then take charge of the plant. The duty of one is to remove the castings to the cleaning department, also to fill the tumbling barrels so that a supply of castings is ready to start work on first thing in the morning. The second gang shakes out the castings and prepares the sand for the following day's work.

Cleaning Department.

The tumbling barrels are arranged in three batteries, each motor-driven and self-contained. There are about 26 mills of all sizes, most of which were made by the W. W. Sly Mfg. Co. Many alterations and improvements have been added by the M.-H. Co. Each barrel is driven independently by a friction clutch, and appropriate jib cranes are furnished for handling the heavier castings and opening or closing the barrels themselves. A large number of grinders are also employed, most of which have been built by the firm. An elaborate exhaust system has been applied throughout. Each rumbler and grinding wheel is fitted with a separate pipe so that, considering the great amount of work being done, the air is remarkably pure and the greatest discomfort suffered by the visitor results from the noise occasioned by so many machines operating at once. Here, also accurate account of each moulder's work is kept as to the number of good castings and wasters. The poor ones are kept for his inspection and every opportunity is given him to improve his output. The cleaning department is in the direct route between the foundry and the factories so that,

TAP HOLES SHOWING ALSO MONORAIL SYSTEM WITH POTS.

as the castings are cleaned, they simply proceed on their way to the department requiring them or to the storage bins.

The plant is fitted throughout with Turnbull electric elevators, while one is struck with the evidences of safety devices and the prominence given to warning cards which are printed in several languages. The sanitary arrangements compare favorably with many office buildings, emphasis being given in every case to strength and cleanliness.

In spite of the fact that so many men and a large number of foremen are required to carry on this work, if differences arise, each and every man may appeal to the superintendent. This is done without, in any way compromising the position of the foremen and the comparatively infrequent cases of serious trouble bear witness to the impartiality and careful administration of the man at the helm.

The organization of the foundry system is complete and intimate, and has for its end the harmonious co-operation of each branch for furthering the interests of the greatest number. For instance, much has been accomplished in the pattern room to save cleaning of castings, and expensive cores are often saved by the help of the moulding and pattern departments.

Trips of inspection and attendance at trade conventions are arranged by the company for all the higher officials and most of the better trade journals are made available to them. The management evidences a personal interest in each department head, his failures and his successes.

The result of this continued co-operation, personal interest and striving for efficiency as well as large sacrifices of dividends on the part of the company has been the gradual building up of the most broadly successful enterprise in Canada which is doing more and more to bring credit to her people and to establish her reputation beyond the seas.

ROW OF CORE BENCHES.

TEMPERATURE CONDITIONS IN COKE OVENS.

A recent issue of Stahl and Eisen contains an important contribution by Professor Oskar Simmersbach, of Breslau, in which the temperature conditions existing during the period of carbonisation and the composition of the volatile product have been carefully determined. The experiments were carried out in a Koppers regenerative oven. The oven was charged with 8¾ tons of coal containing 22.7 per cent. volatile matter, 6.32 per cent. ash and 12.1 per cent. water. This yielded 79.86 per cent. coke. The coal was carbonized for a period of twenty-nine hours. The temperature rose gradually during this period, the concluding readings being 1090° C. at a quarter the distance from the charging side, 1120° C. in the centre, and 920° C. at a quarter the distance from the discharging side. These temperatures correspond to the centre of the carbonized mass. In the gas space above the coal, the finishing temperatures were respectively 870°, 860° and 810°. The resulting coke contained 88.53 per cent. carbon, 2.56 per cent. volatile matter, and 8.91 per cent. ash.

Keep the Flag Flying.—It should take more than the temporary check British commerce has received to compel our manufacturers to lower their colors, says a contemporary, and what is true of British commerce is likewise of Canadian. Already we hear from Berlin that everyone in the German capital now realizes that German overseas commerce has been destroyed, and that the elimination of the Fatherland as a factor in the world's trade is complete for many years at least. Surely with this before them it behoves our manufacturers to go with all their power for the new fields open, rather than adopt a policy of false economy.

C. J. Gibson has been appointed Town Engineer of Bowmanville, Ont.

PRODUCTION METHODS AND DEVICES

A Department for the Interchange and Distribution of Shop and Office Data and Ideas Evolved from Actual Practical Application and Experience

FINISHING ECCENTRICS IN MEDIUM-SIZED PLANT.

By J. P. Sanderson.

THE production of work in the medium-sized plant with a reasonable speed and a degree of interchangeability commensurate with present-day methods often involves problems more difficult of solution than either the jobbing shop or the large institution, which has an unlimited market to cater

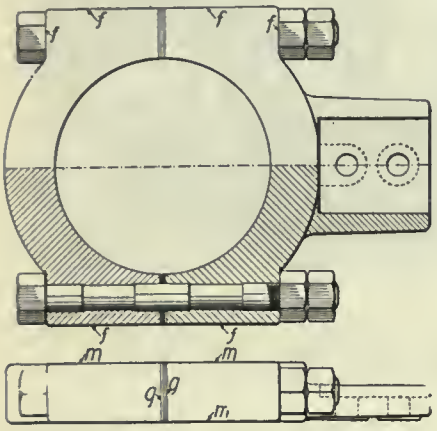

FIG. 1. ECCENTRIC STRAP, SHOWING LOCATING POINTS.

to. The greater number of plants in Canada and the United States embraces those whose market and capital investment are not large enough to justify the installation of special machinery, while, at the same time, jobbing shop methods would be far too slow and expensive. The plant from which the following article was taken is engaged largely in the manufacture of hoisting engines, the rest of the product being made up of cable-ways and saw mill machinery. The eccentric straps spoken of are used on two types of engines—the double cylinder hoisting engine, being reversing type, requires four, while the double cylinder donkey type takes only two. The output of from one to three engines per day along with extras makes the requirement of straps about 40 per week.

The castings are made in batches of 500, which are easily finished on the drill presses in a week, while one Kempsmith milling machine does its share of the work in half that time. The moulding is of no special interest, the work being done with a matched plate on a squeezer moulding machine. In the cleaning-room especial attention is given to the first locating points (f), Fig. 1. The first machine shop operation consists of very lightly disc grinding both sides of the rod half and one side of the other half, as shown by (m) Fig. 1. This little extra grinding permits of setting up two pieces or a complete pair in the milling machine, and can be done at the rate of about 125 pairs per hour.

Milling the Faces.

The second operation consists of milling the faces, marked (g), Fig. 1. The fixture for this purpose is shown in Fig. 2. It consists of a flat raised plate B, having locating tongues to fit into the grooves of the miller table. Much of the webbing and parts added for strength only are not shown, so as to avoid complication. The work is located vertically by the three small rectangular pads indicated by dotted lines in the plan view and horizontally by the four posts (p) provided with set screws and lock nuts. Enough play is allowed here to provide for the slight inequalities of machine-made castings.

The fastening is accomplished by means of the locating piece (b) and the bar clamp (c). These are both operated by eccentrics (g) on the handles (h h). The motions of these cams can be adjusted by the nuts on the other ends of the clamping bolts. The piece (b) is simply a forging shaped like the letter L, the vertical part of which is drilled to receive the two small rubber pads (f f). It is drawn up against the inside of the two eccentric parts by raising

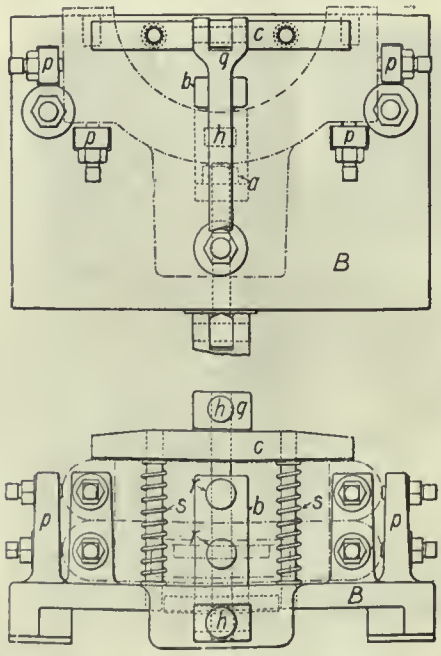

FIG. 2. FIXTURE FOR MILLING CLAMPING SURFACES OF STRAPS.

the lower lever (h), which is made very short, as pressure enough to hold the work against the back posts (p p), while it is being clamped down, is all that is required.

The clamp (c) is tightened against the work by pulling the upper lever (h) downwards and forward, which lever is long enough to conveniently give the requisite pressure. The springs (s s) are stiff enough to raise the clamp and keep the lever in a vertical position when the fixture is opened. The operation is very simple. The top lever being raised and the back one being lowered, the two components of a complete strap are slipped into place, the rod half on the bottom and the front half on top

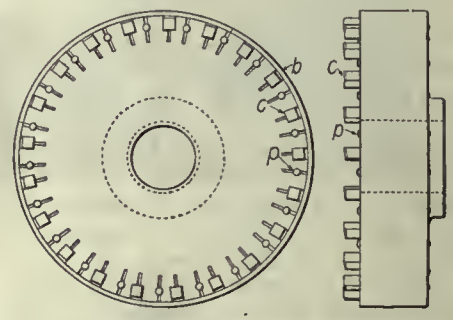

FIG. 3. TYPE OF MILLING CUTTER EMPLOYED.

(ground side down). Pulling the pieces against the stops and clamping them down takes but an instant, and the work is ready to proceed.

The Milling Cutter.

The milling cutter used is shown in Fig. 3. The body of this tool is made of the best cast iron obtainable, and supports the square tool steel cutters clamped by standard taper pins, as is often done. A steel band (b) is shrunk over the whole, both for the purpose of adding strength and protecting users from being caught by the many grooves on its periphery.

The peculiarity about the cutter is that the teeth are ground to cut both ways, and on both inside and outside edges. Its size is such that one leg of the strap is milled by the up-going side of the cutter, while the other leg is being machined by the down-going side. Thus the machine is only fed a distance equal to the width of one leg of the casting. The machine is also fed in both directions, one pair of straps being removed and another being placed in position between each feed reversal; the cutter running continuously. The grinding of clearance on both sides of the teeth makes a little extra work for the tool-room, but the time saved and the finish produced well repays for this.

The Drilling Fixture.

For drilling the bolt holes, two fixtures shown in Fig. 4 are used. These consist of angle plates, as shown, provided with locating surfaces (f f) for the finished faces of the straps; otherwise they are located by the pins (k k) and small back pads at (f f). The work is placed in the position shown by the dotted lines. It is first pressed against pads at the back by the two cams (d) operated by short levers (h). The clamping up is done by the two eccentric cams (c c), which force up the blocks (a a) by means of the lower levers (h h).

The blocks (a a) are of cast iron, and are fitted to slide freely in slots cut in the angle plate. They are kept in place by steel plates (p) and screws, as shown. Also a small piece of sheet metal is used to keep borings out of the slots. The drill bushings (b b) were hardened and fitted in the usual way.

For doing this work an auxiliary spindle was added to each of two radial drilling machines. This spindle has a vertical feed, but is not connected with the horizontal feed screw, being simply moved by hand to any desired position and clamped there. When out of use it is placed at the end of the arm close to the body of the drill and the key in the horizontal driving shaft removed. These extra spindles enable both holes to be drilled simultaneously and, besides this, have been found very useful for a great many other pieces of work.

Two machines and two jigs are engaged in this work, and are easily operated by one man. High-speed drills are used, and the two drills give the machine about all it wants to do. The holes for attaching the eccentric blade are drilled in a very simple little jig. The work is located by the two holes already drilled, and the drill bushings are carried by a hinged piece which fits into the depression prepared to receive the flat blade. These holes are also bored with high-speed drills from a multiple head arranged for the two holes required.

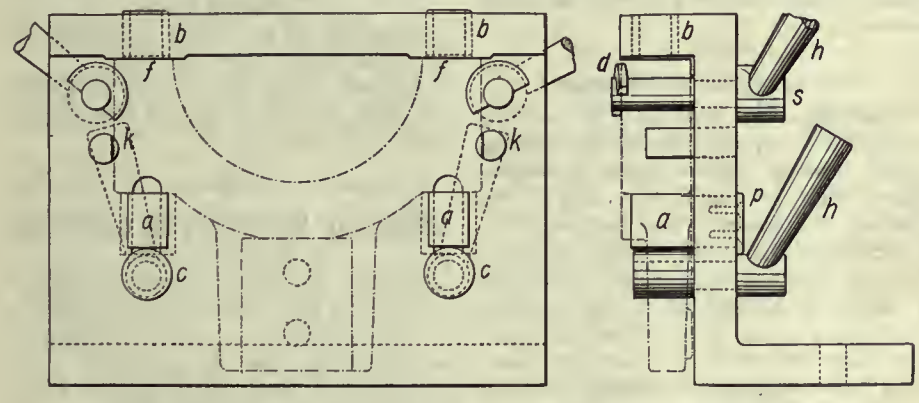

FIG. 4. DRILLING FIXTURE FOR CLAMPING BOLT HOLES.

Completing the Work.

The bolts are drop forgings finished in the turret lathe, and the liners of three thicknesses are prepared on a small punch press, the process of punching, blanking and flattening being carried on in a progressive operation. After assembling, the straps are bored in a simple holding fixture on a heavy turret lathe. Previous to this, however, they are given a coat of paint so that, when finished, there will be no paint to interfere in the fitting of strap to eccentric.

Throughout the whole procedure the object has been to produce a positively interchangeable part and still keep all the shop machinery available for other work as well. Accurate limit gauges are provided for the various operations as well as a carefully-prepared sample of the completed job. A rigid inspection of the pieces is made before going to the stock-room.

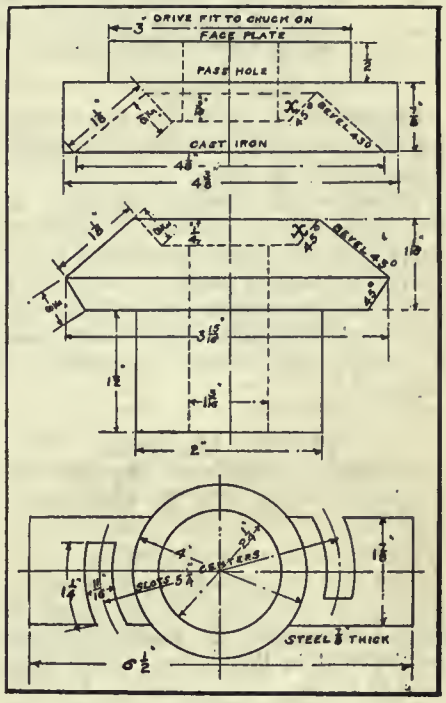
FIXTURE FOR BORING BEVEL GEARS.

By F. B. Morgan.

BEVEL gears are at best very tedious things to true up on the lathe for boring and if many are to be done a great loss of time results. The little fixture here illustrated not only saves the time usually expended in chucking and truing up, but holds the work so firmly that the maximum cuts can be taken. It consists simply of the plate shown in the upper part of the illustration and a suitable quick-acting self-centering clamp shown at the bottom.

The plate has a ½ inch boss turned to fit the hole in the lathe face plate with a loose drive fit. On the opposite side and exactly concentric with this boss is the locating surface (x). This is turned the reverse of the bevel gear face with approximately the same angles, but with plenty of clearance. Plates have been used quite satisfactorily without the small inside bevel, but where the gears are machine moulded or are fairly uniform, this is a considerable advantage in its use, although care must be taken not to make it too large.

The strap practically explains itself. Its main features are the circular slots and the locating boss. The studs are made of ⅝-in. machinery steel and are fastened tightly into the face plate. They serve also as drivers for the work. This fixture is simple and can be made by the mechanic in spare time. Each plate and clamp is suitable for quite a range of gears, and but a small number would be required for a complete equipment.



FIXTURE FOR BORING BEVEL GEARS.

A TRADE FOR EVERY MAN.

SPEAKING on "The Gospel of Labor" at the Broadway Methodist Tabernacle, Toronto, on the evening preceding Labor Day, Rev. Dr. Young emphasized the importance of every man having a trade or profession. The observance of this rule, he said, would relieve many cases of distress when children of wealth, unexpectedly thrown on their own resources, would be confronted with the necessity of earning their own living. It was not a disgrace but an honor to have a trade, the preacher maintained. Time and again great men had come from the ranks of labor. There was no bar to prevent a child of labor or even a laborer himself from reaching the goal of success.

Organized labor, he continued, is entitled to respect and honor for the good it has accomplished in the bringing about of improved conditions in the lives of workingmen. While all great revolutions have been marked at times by certain excesses, yet these are only incidental, the natural outcome of extreme enthusiasm; so the great labor movements have sometimes been accompanied by excesses, but these should not be considered in any detrimental spirit. The world to-day owes much to organized labor.

Question and Answer Series for Foundrymen

Foundrymen having difficulties in connection with their work are invited to forward particulars of them to this department for solution. The greatest possible care will be taken to give only reliable and tried-out advice on all questions submitted.

Brass Mixture.

Question.—We would like to get a dependable formula for brass separator bushings.—A. K. H.

Answer.—An excellent mixture for this purpose is as follows:—Copper, 83 parts; tin, 5 parts; phosphor—tin, 2 parts, and lead, 9 parts. Another mixture which has given good results contains copper, 83 parts; tin, 7 parts; lead, 9 parts; and yellow phosphorus, 2 ounces.

• • •

Flux for Aluminum.

Question.—Kindly tell us what you consider the best flux for aluminum.—R. T. S.

Answer.—Chloride of zinc is an excellent flux for aluminum. It is not expensive, is easy to obtain, and gives the very best results. It should, however, not be used in liquid form unless great care be taken.

• • •

Porous Automobile Cylinders.

Question — We make automobile cylinders, and have experienced a great deal of trouble from shrink holes in the bosses. We have changed our mixture several times, but it does not seem to remedy the trouble. What would you advise to overcome this difficulty?—J. M. C. Co.

Answer.—This is a question of uneven cooling and not of the composition of your iron mixture, as the light parts of your casting cools quickly, leaving the heavy boss fluid. Gate your mould if you can on the thinner parts of the casting and cut down the thick section on your pattern if possible. You can also place chills against the heavy parts. Small chills can be placed in the core, and will fall out with the core sand.

• • •

Loss in Melting.

Question.—After making several tests in our foundry, we find our good castings average only 75 per cent. of the iron charged in the cupola. We know this loss is very high, and would like your opinion as to the cause or causes.—J. T. R.

Answer.—You do not state whether you charge the bad castings of each heat against the loss or not. In any case, your loss is entirely too high, and there must be some mistake in estimating the amount of iron charged and the amount tapped out. Not knowing what grades of scrap you use, it is difficult to state definitely what your average loss should be. Pig iron will average 6 per cent. loss, and scrap will vary from 7 to 15 per cent. loss, depending on its condition when melted.

• • •

Cast Iron Pots for Melting Lead.

Question.—We have been making cast iron pots for melting lead, and as long as coke was used as a fuel had no trouble. Since using oil, the pots burn out rapidly, and show pin holes and cracks. We tried a mixture of steel scrap, 300 lbs.; machinery scrap, 1,000 lbs.; we also tried a mixture of steel scrap, 100 lbs.; machinery scrap, 1,800 lbs.; and No. 3 foundry, 100 lbs. The first mixture gave the best results when we added 5 lbs. ferro-manganese to each ladle of 1,800 lbs. We melt much more iron than we need, and pour it into pigs, and by so doing find that we get a cleaner and closer grain product. Tell us how we can overcome our difficulties.—A. G. B. Co.

Answer.—It is not advisable to melt your iron more than once, as melting it and pouring it in pig only increases the sulphur. The oil contains a higher percentage of sulphur than the gases from the coke fire, and the pots are kept at a high temperature with more free oxygen in the oil fire than in the gases from the coke; in which case the iron is burnt. If you will secure a better mixture of air with your oil and less free air in the chamber arond the pots, you will find that the life of the pot will be much longer.

• • •

Dry Sand Facing for Brass.

Question.—Can you give us a good formula for dry sand facing for making sharp, smooth, light castings in yellow brass, such as chandelier work? We mix about a barrel at one time.—R. T.

Answer.—There are several preparations on the market suitable for use as a facing in making fine brass castings. They come mostly in powdered form and are dark red brown in color and make very fine sharp, smooth castings. If the moulds are to be skin dried, they must be sprayed with stale beer or molasses water, but if the mould is to be dried or baked in the oven the sand should be tempered with molasses water at first to give a bond so that the impressions will withstand the rush of metal. The quantity of molasses to be used depends on the class of work you are making. The writer has found a mixture of two of water to one of molasses very satisfactory.

• • •

Brass Mixture for Fittings.

Question.—Will you kindly give us a mixture for gasoline engine fixtures also one for propeller wheels using all new metals but getting as cheap a mixture possible.—S.L.M.

Answer.—A very good mixture for brass fittings is:—Copper, 85 per cent.; zinc, 10 per cent.; tin, 3 per cent., and lead 2 per cent. This mixture can also be used for propellers but a better one is:—Copper, 88 per cent.; tin, 10 per cent., and zinc, 2 per cent.

• • •

Mixture for Soldering Iron.

Question.—We would like a first-class mixture for electric soldering irons.

J. D.

Answer.—A mixture that has been found to work well in soldering irons is as follows:—Copper, 96 per cent.; zinc, 3 per cent.; phosphor-tin, 1 per cent.

• • •

Core Difficulties.

Question.—We are making castings with some very small intricate cores in them, and have had a lot of trouble from the cores blowing. We have tried several different mixtures of sand but have not obtained good results. Can you give us a core sand mixture that will stop this trouble.—T.S.

Answer.—If you will get some ground silica sand commonly known as sugar sand, I think it will overcome your trouble. This sand can be mixed 80 to 90 parts to one of raw linseed oil, and very seldom needs a vent in small cores. You can get this sand from any foundry supply house by the barrel or car.

• • •

Buying Coke.

Question.—What rule would guide you in buying good coke?—T. W. P.

Answer.—Good coke should be low in ash, high in carbon, and as free as possible from sulphur.

METALLIC MOULDS FOR CASTINGS

By Walter T. May.

MAKING castings in metallic moulds is not at all a new process, although during the last few years it has been developed on somewhat new lines, and is being still further developed in places where large numbers of identical castings are needed. Probably, with some limitations in regard to size, firms making articles with parts which are interchangeable will eventually use these permanent iron moulds very largely, especially as with a little care there need be only the minimum of machining done to the castings, thus making it possible to turn out sufficiently finished castings for many

things. In the cheaper class of goods turned out by the thousand, the production of cast parts practically finished is of much importance, owing to the fact that the less the things are handled the easier their first cost can be kept.

It will usually be found that, to ensure economy in production the cost of plant will be somewhat heavy when its first installation alone is considered, but the saving in cost of manipulation afterwards gives a large ultimate profit. It is in this way that American practice enables makers to cut prices very largely, because in the first place work is standardized, and as far as possible interchangeable, thus reducing the numbers of parts; then the best appliances for turning out the parts are obtained, no hesitation being shown in scrapping as appliance if a better can be had, and what is quite as important, wages rather rise than fall as the various appliances are introduced.

Initial and Production Costs

In the case of permanent-mould making, the makers of the moulds are well paid, and for this reason the mould is costly, but as against this must be set off the low cost in producing castings from the moulds, as even against the best machine moulding there is a large reduction in both cost and time. Supposing a mould costs $5 and produces 1,000 good castings, the cost of moulding runs out to approximately a half cent per casting, as against from 12 to 18 cents by hand work, and the castings being to all intent and purposes identical in size and form, they can be very economically handled in the machine rooms.

As against these reductions there is probably a small increase in the cost of working the moulds, this being dependent on the organization of the moulding floor; but when worked in series in a systematic manner, and with a continuous running cupola or a battery of crucible furnaces of a size to keep up continuity of working, the increased cost of manipulation can be kept down to quite a small thing. One or two moulds only would be a nuisance as a rule, but with sufficient to keep a regularly organized staff of men going steadily, the work would be done at a small expense and with considerable rapidity so far as the number of castings produced in a given time is concerned. Instead of taking an hour to produce a mould in sand, four castings could be produced in the hour under favorable conditions, as the moulder would be eliminated after the metal mould was secured, men trained to handling the casting operations only being necessary.

Metal Mould Troubles.

At first, metal moulds work badly, as they have to get seasoned to the work, and a good many wasters would be turned out at first; but as the moulds get seasoned the wasters disappear, and eventually become rather rare. There is, however, this to be said about wasters; they cost only the amount which is expended on melting and pouring, which, as a rule, is a comparatively small item, while it is not comparable with the loss involved where wasters are produced in ordinary sand moulding, which involves the loss of the moulder's time in every case.

The metal of which the moulds are made should be low in combined carbon and high in graphitic carbon, while the silicon content should not be too high. High silicon and combined carbon would probably cause the moulds to grow and become deformed, while cracking would certainly take place. The moulds are not chills, and should not be allowed to get much above 350 degs. F., while working, this not being difficult to manage owing to the castings being turned out as soon as set, or at least in the case of iron at about an orange-red. With other metals generally a lower temperature would be used both for pouring and removal from the mould, the shape of the castings, the metal used, and individual practice being the determining factors for turning out the castings. To ensure the quick removal of heat, the moulds must be thick, say, from 2 in. upwards, according to the bulk of molten metal dealt with, each mould having to be treated according to its own particular purpose.

Hinged moulds should work freely, but without excessive play, and built-up moulds should have freely-fitting guide dowels to keep the parts in their proper positions. Wrought-iron handles will have to be cast in, as everything gets too hot to hold with the bare hands, and unless proper facilities are afforded in this direction trouble will certainly occur. Venting is only needed to carry off the confined air, as gases will not be generated, owing to the fact that clean metal must be used, and in most cases a slight amount of venting at the joints of the moulds will be all that is necessary. In regard to the metal used in making the castings, it must be clean and fluid, and in the majority of cases it is desirable to use some flux of a deoxidant character to remove all traces of undesirable matter.

In melting it will be found that the greatest fluidity occurs soon after melting point is reached, and that, with accretions of temperature, the molten metal becomes dull and sluggish, refusing to run up sharply, and in some cases only producing porous castings of a very unsatisfactory character, quite independently of the form of mould used. To some extent fluxes can be used to recover this overheated metal when it is again melted, while, provided the right form of flux is used, passable castings can be secured, but this should not be required, since proper melting makes their use unnecessary.

Where iron cores are used, these should be made of soft cast iron like the moulds, and for some time a coating of plumbago should be used with them, both for getting into good condition and to act as a lubricant. Their removal from the castings should take place at the interval between the solidification of the metal and the commencement of contraction, which, although brief, is yet long enough to enable the cores to be taken out. If the metal contracts before the cores are taken out, much difficulty will be experienced in removal. There is nothing to prevent sand cores being used, provided they are dried thoroughly and coated with plumbago, but provision must be made for venting when these are used. In removing iron cores, where possible, they should have a spiral or screwing motion imparted to them.

The Operator Feature.

In dealing with metal moulds, the greatest trouble will be found with the operators, as at first they will find it difficult to get the exact time at which the mould should be opened and the casting thrown out, very many men treating these moulds as chills. For this reason it is at first desirable to deal with such things as wheel blanks or articles of a like character which do not surround any part of the mould, and from these work to other forms, as at first it is somewhat difficult to judge the proper time for opening the moulds.

Given good soft iron moulds, clean metal, and operators who take an interest in the work, making castings in permanent moulds should very largely reduce costs of producing articles where large number of similar parts can be utilized, as practically the moulder's work is eliminated after the moulds are once made, thousands of castings being obtainable from each mould when they are properly handled. Practically all metals and alloys can be dealt with, but there will necessarily be differences in their treatment. Above all, it must be remembered that the process is not a new one, but simply a development of a practice which has been in use for a considerable number of years in a slightly different form.—From a recent article in the Foundry Trade Journal.

Locomotive Cranes recently have been fitted with small turbo-generator sets to furnish current for lifting magnets with which the cranes are equipped. This eliminates the dragging back and forth of power wires along the track on which the crane operates.

Series of Practical Questions and Answers for Mechanics

Every care is being taken to include only pertinent practical questions, and give same direct, reliable answers. Catch questions will be avoided. Attention is drawn to the alternating course in arithmetic, a concurrent study of which is recommended with that of the Question and Answer Series.

POWER CALCULATIONS.

WORK is measured by taking account of force and distance. The British unit of work is the foot-pound or one pound of force through one foot of distance. In performing work is required, another dimension must be taken into account. This is time. Thus power is the ability to do a certain amount of work in a stated time. The unit of time varies, but the minute is usually adopted. That is, a horse power represents 33,000 foot-pounds of work performed in one minute. This may mean the lifting of 33,000 pounds one foot high, 330 pounds 100 feet high, or it may represent the moving of a body 1,000 feet in a horizontal direction against a frictional resistance of 33 pounds. It matters not whether the direction of the applied force is vertical, horizontal or circular so long as the three dimensions are known namely, its value in pounds, the distance it moves in feet and the time in minutes required to travel the above distance.

* * *

Question.—An elevator lifts 21 people 60 feet in 3 minutes. Counting 12 people to the ton, what is the work done and what is the power of the machine?

Answer.—If 12 people weigh 1 ton, 21 would weigh $\frac{21}{12}$ tons or $\frac{21}{12}\times 2{,}000$ pounds $= 3{,}500$ pounds.

$3{,}500 \times 60 = 210.000$ foot-pounds, which is the work done.

210,000 foot-pounds in 2 minutes = 105,000 foot pounds per minute, and as one horse power=33,000 foot-pounds per minute, therefore the power of the elevator is

$$\frac{105{,}000}{33{,}000} = 3\frac{2}{11} \text{ horsepower.}$$

* * *

Question.—If it requires 300 pounds pressure on the tool of a lathe to take a cut 3-16 inch deep at a 32 feed, what horse power motor would be required to operate the machine. The diameter of the work is 28 in., the speed of the driving pulley which is geared 4 to 1 is 40 r.p.m. and the efficiency of the gearing is 85 per cent.

Answer.—The work makes $\frac{40}{4} = 10$ r. p. m. Circumference of the work is $\frac{28}{12}\times\frac{22}{7}\times\frac{22}{3}=\frac{2}{3}=7\frac{2}{3}$ feet. Speed, therefore, is $7.33\times 10=73.3$ ft. per min. Force is 300 pounds, and horse-power then is $\frac{73.3\times 300}{33{,}000}=\frac{73.3}{110}=.666$ h.p. On account of the gearing losses, this represents 85% of the required power. Power needed then is $\frac{.666}{85}\times 100=.784$ h.p.

* * *

Question.—The arm of a prony brake is 3 ft. long. If the engine run at 120 r.p.m. and the load on the scale be 20 pounds, what actual power is the engine developing?

Answer.—The number of foot-pounds developed would be the circumference of a circle of 3 ft. radius multiplied by the r.p.m., multiplied by the load on the scale. This is $6\times\frac{22}{7}\times 120\times 20$, and horse-power $=6\times\frac{22}{7}\times\frac{120\times 40}{33{,}000}=2.74$ h.p.

* * *

Question.—Instruments show that the electrical power input to a boring mill is 27.8 amperes at 220 volts. A previous test of the motor showed the stray power and other losses to be 3.8 amps. What horse-power is required to operate the machine?

Answer.—One horse-power=746 watts. Number of watts used is $24\times 220=5{,}280$. Amount of horse-power is $\frac{5280}{746}=7.07$h.p.

* * *

Question.—In the above example, the large gear is 35 inches in diameter. If the speed be 1½ r.p.m. what is the direct pressure against the gear teeth?

Answer.—The circumference of the gear is $\frac{35}{12}\times\frac{22}{7}=\frac{55}{6}$, and surface speed $=\frac{55}{6}\times\frac{3}{2}=\frac{55}{4}=13.75$ ft. per min.

7.07 horse-power $= 7.07\times 33{,}000 = 233{,}310$ foot- pounds.

Pressure on gear teeth $=\frac{233{,}310}{13.75}=$ 16,968 pounds or 8½ tons.

* * *

Question.—A triple threaded worm drives a 72-toothed gear. How many revolutions will be made by the gear for every 100 made by the worm?

Answer.—For every revolution of the worm, the gear advances three teeth. For 100 revolutions of the worm the gear would advance $3\times 100=300$ teeth or $\frac{300}{72}=4.16$ revolutions.

* * *

Question.—How fast could a 3 ton elevator be raised by a 4 h.p. motor, considering the unbalanced weight of the elevator to be 500 pounds and the efficiency of the machinery to be 75 per cent?

Answer.—A four h.p. motor with gearing of 75 per cent. efficiency could perform $\frac{33{,}000\times 4\times 3}{4} = 99{,}000$ foot-pounds of work.

The loaded elevator weighs $(3\times 2{,}000)+500=6{,}500$ lbs. With a power of 99,000 foot-pounds per min., this load could be raised $\frac{99{,}000}{6{,}500}=15.23$ feet per min.

* * *

Question.—A pump working 8 hours per day is required to keep a tank, which is elevated 60 feet, full of water. The tank is 14 feet in diameter, 16 feet high and is three-quarters emptied every day. With friction and mechanical losses amounting to 40 per cent., what size motor would be required to operate the pump?

Answer.—The volume of the tank is $7^2\times\frac{22}{7}\times 16=\frac{7\times 7\times 22\times 16}{7}=2464$ cu. ft. Weight of water $=2{,}464\times 62\frac{1}{2}=154{,}000$ pounds or $\frac{3}{4}\times 154{,}000=115{,}500$ pounds to be raised in 8 hours. The height is $60+16=76$ feet. 115,500 pounds in 8 hours $=\frac{115.500}{8\times 60}=240.625$ pounds per min. To raise this 76 feet requires 76×240.625 foot pounds or $\frac{76\times 240.625}{33{,}000}$ h.p. With a loss of 40 per cent. The rating of the motor would be, $\frac{76\times 240.625\times 100}{33{,}000\times 60}=.923$ h.p.

U.S. BRASS FURNACE PRACTICE.

BRASS Furnace Practice in the United States is the title of Bulletin No. 73, issued by the Bureau of Mines, Washington. D.C., containing the results of an investigation undertaken to ascertain the melting and fuel losses in present brass-melting practice and to

indicate, as far as possible, methods by which these losses might be reduced. Dr. H. W. Gillett, alloy chemist of the Bureau, conducted the investigation, and is the author of the bulletin.

Magnitude of the Industry.

The magnitude of the industry and other important features are indicated in the accompanying extracts from the preface of Charles L. Parsons, chief of the Division of Mineral Technology of the Bureau:

There are in America to-day some 3,600 plants melting brass and bronze, and 1,000 of these melt non-ferrous alloys exclusively. Allowing for the present recovery of waste metal, it appears that in current practice, between the purchase of the raw metal and the completion of the finished product, at least 5 per cent. of the original metal is lost. In the melting of non-ferrous alloys, taking into consideration all such alloys and all furnaces and fuels used, it is shown that from 90 to 95 per cent. of the heat units in the fuel do no useful work. On the basis of $120,000,000 being the value of the metal passing through brass and bronze furnaces each year, a 2½ per cent. melting loss, equivalent to 5 per cent. loss on metal bought, means an annual loss of $3,000,000 in metal alone. Simply reducing the average metal loss to that of present best practice would mean a saving of over $1,500,000 a year. If fuel efficiency and crucible life could be brought from present average to best practice, half million dollars more, at least, could be saved.

Proper Records and Control.

The lack of proper control and of proper records in most furnace practice has been brought out through the investigation. Few of the plants are under technical control. The firms that keep proper records, and hence have the necessary knowledge, invariably employ a trained metallurgist to supervise the melting furnaces, and these firms almost always have the lowest losses. The lack of technical control is emphasized by reports of metal losses varying from one-tenth of 1 per cent. to 22 per cent., and fuel efficiency from 1½ to 16 per cent. The need for thorough technical control in the majority of our foundries and casting shops is clearly evident.

Operators' Inefficiency.

Another waste not so readily expressed by figures, but which none the less really exists, is the loss of efficiency of the workers in the industry through occupational disease and accidents due to a lack of safety precautions. A few of the firms reporting have given careful consideration to the prevention of disease and accidents, and it is shown that by the enforcement of simple, proper precautions, occupational disease may be eliminated and the non-ferrous alloy industry placed beyond reproach as to the health and safety of its employees. Investigation has also magnified the need of an efficient electric melting furnace in the alloy industry, and a pyrometer which can be used as a workman's tool. These two problems are now under investigation by the Bureau of Mines.

Melting Loss and Copper Consumption.

The losses, both of metal and fuel, in melting brass and bronze are large. The net loss of metal, if all recovery of any sort be deducted and if all the brass and bronze alloys be included, will average not less than 2.5 per cent. Extreme figures reported are 22 and 0.1 per cent., the former figure being unusual and not representing regular practice and the latter not being verified. Extremes of 8 and 0.5 per cent. are well substantiated. The total melt will average about twice the raw metal bought, because of the remelt of crop ends and scrap in rolling mills and of gates and sprues in foundries. Some foundries making light castings melt 3 lb. of metal to get 1 lb. of castings. A ratio of 2 lb. of metal to 1 lb. of castings is common, and 1½ to 1 is low. If, then, the whole industry be considered, a loss of 2.5 per cent. on the gross melt is equal to about 5 per cent. on the raw metal bought.

The consumption of copper in the United States in 1911 was about 680,000,000 lb. If two-thirds of this total, or 450,000,000 lb., be considered as having been used for making brass and bronze, and if the average copper content of the alloys used be assumed as 80 per cent., the deduction would be that about 560,000,000 lb. of brass and bronze products was made from new copper. It seems conservative to estimate that at least two-thirds of the copper consumed in the country is in the form of brass and bronze, as W. S. Lathrop states that one corporation, making mainly wrought yellow brass, uses in its various plants approximately a third of all the copper consumed in the United States. To this must be added the old metal used. Half as much old scrap or alloyed ingot as new metal—that is, 280,000,000 lb., seems a fair estimate, so that 840,000,000 lb. should represent the total metal bought. The average value of brass and bronze being taken at 15c a pound, by this method of figuring $126,000,000 would be the value of the metal passing through the brass and bronze furnaces of the United States in a year. For purposes of computation the estimate of $120,000,000 has been taken.

A 2½ per cent. melting loss, equivalent to a loss of 5 per cent. on the metal bought, thus means $3,000,000 a year lost in metal alone. Could this be reduced to the 2½ per cent. loss (equivalent to 1¼ per cent. on the melt) shown by good practice, a saving of $1,500,000 a year would result. If the fuel consumption and crucible life were brought from the average practice up to good practice, and if furnaces that cut down or eliminate crucible cost and allow greater production with less labor cost were used wherever practicable, a saving of at least another half million would be made, or a total of $2,000,000 a year that the non-ferrous alloy industry of the United States might save merely by bringing average furnace practice up to the standard of the best practice.

Fuel Efficiency.

The fuel efficiency is found to vary between 1½ and 16 per cent., the average being 4 to 9 per cent. If all fuels and all furnaces be considered it is doubtful whether the average fuel efficiency is more than 7 per cent. of the theoretical.

Dr. Gillett sent out about 2,000 lists of questions to 1,650 plants, only 230 of which sent any data, and about 50 of these stated that they had no records. The information obtained was supplemented by personal visits to some 80 foundries and rolling mills in 13 States. It is believed, however, that the data obtained represent the practice of the great bulk of firms melting brass.

ILLUMINATING ENGINEERS' SOCIETY CONVENTION.

AT the Illuminating Engineering Society Convention, which meets in Cleveland, Ohio, from September 21 to 26, the accompanying list of papers, among others, will be read and discussed:—

Factory Lighting—By Hogue and Dicker.

Planning for Daylight and Sunlight in Buildings—By Marks and Woodwell.

Notes on the Ulbricht Integrating Sphere and Arc Lamp.

Effect of Room Dimensions on Efficiency of Lighting Systems—By Ward Harrison.

A New Standard Light Source—By L. A. Jones.

Artificial Daylight: Its Production and Use—By M. Luckiesh and F. E. Cady.

Characteristics of Gas-filled Lamps—By G. M. J. Mackay.

Recent Improvements in Gas Lamps—By a Welsbach representative.

The Locomotive Headlight—By J. L. Minick.

Present Practice in Machine Shop Lighting—By Powell and Harrington.

The Development of Daylight—By E. J. Brady.

PROGRESS IN NEW EQUIPMENT

A Record of New and Improved Machinery and Accessories for the Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

IMPROVED MOTOR DRIVEN PATTERNMAKER'S GRINDER.

C. H. BESLY & CO., Chicago, have brought out an improved motor-driven patternmaker's grinder, the following illustrated article being relative to same. This combination machine (Fig. 1) which is claimed to be a big labor saver on wood pattern work, has a steel disc wheel faced with Garnet paper for grinding flat surfaces and external curves; and a drum sanding attachment for grinding internal surfaces —both straight and curved. The construction throughout is fully up to the standard of the very highest grade of machine tools, the flat disc wheel, adjustable work tables and various work-table attachments, graduated, insuring extreme accuracy in angularity and dimension at trifling labor cost.

With this machine an apprentice is capable of performing much of the work which heretofore had to be done by a skilled workman. Cheaper pattern lumber can also be employed, as the machine will grind any kind of wood, and even nails or screws which may protrude to the ground surface. What has heretofore been considered trimmer work can be done quicker and better on the grinder, as well as much of the turning and smaller machine planing, and a large portion of the hand work, such as sanding, planing, cornering and general hand fitting and finishing.

In addition to doing the work quicker, the grinder produces straighter flatter surfaces, better glue joints, more accurate angles and dimensions as well as better finish. Ground surfaces are claimed to make the best glue joints

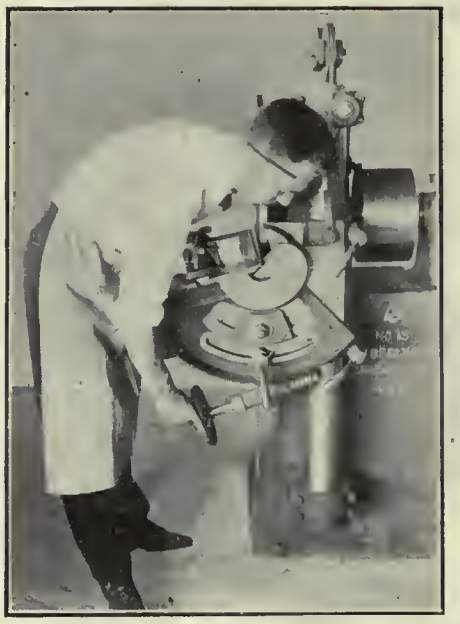


FIG. 2. MOTOR-DRIVEN PATTERNMAKER'S GRINDER.

known for wood patterns, and with this machine an ordinary workman can make as good a glue joint as an expert. Same applies to jointing split core boxes. An apprentice can renew the grinder abrasive material, but it takes an expert to sharpen knives for trimmers, machine and hand planes, etc.

The grinding wheel is of steel 30 ins. diameter and similar to wheels used on disc grinders, except that, for grinding wood, the abrasive sheet or circle is cemented to the wheel while in position on the machine and without the use of a press. A special quick-drying cement is used for this work. A worn out circle may be removed and a new one made ready for use in a few minutes time.

The spindle construction is similar to other high grade disc grinders, in that provision is made for taking up all end play so that extremely accurate work may be accomplished. The disc wheel is served by an adjustable work table 14 ins. wide by 40 ins. long, which may be tilted by means of the worm gear hand wheel (Fig. 2), and locked at any angle from 75 degs. to 135 degs. from the plane of the grinding disc. Large distinct graduations are provided to indicate this angular position.

In order to be able to change the angular position in one operation, the table is hung from one end and tilts from an adjustable circular gibbed bearing so stationed that edge of table always remains 1-32 ins. from face of grinding disc regardles of the angular position of the table top (Fig. 2). This is an important feature because ordinary tilting tables incline to move away from the grinding disc when tilted; naturally

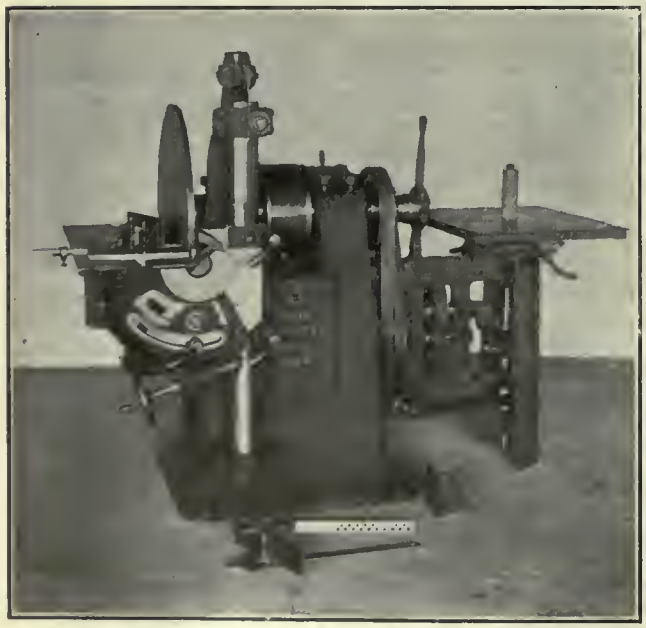

FIG. 1. MOTOR-DRIVEN PATTERNMAKER'S GRINDER.

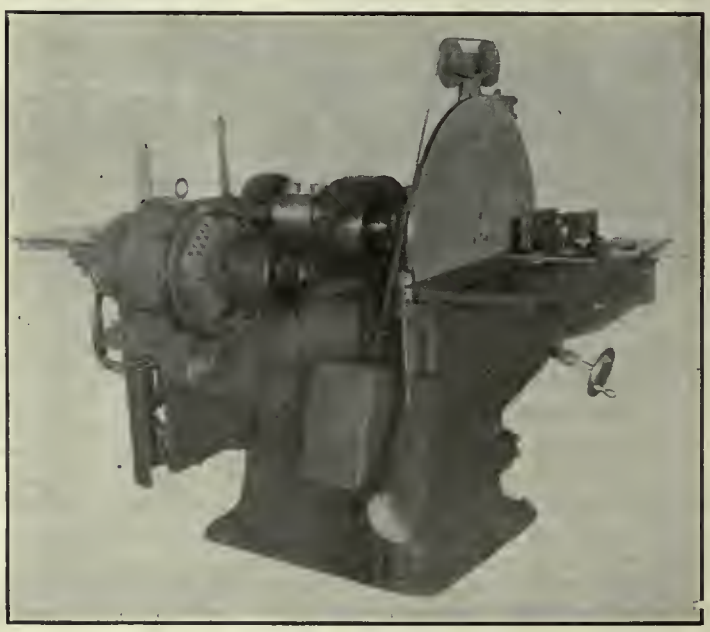

FIG. 3. MOTOR-DRIVEN PATTERNMAKER'S GRINDER.

requiring a second adjustment to bring them up to the face of the wheel. The work table has vertical adjustment of 25 ins., and may be swung away from the grinding disc for convenience in resetting the wheel or for facing off extra large patterns. It is also counterweighted, and each adjustment is locked with a single handle nut insuring easy and quick manipulation. Four work table attachments, indispensable on wood pattern work are provided as follows:

The sizing circle guage for grinding cylindrical or conical work like core prints.

The sliding bevel gauge, graduated for accurately squaring or beveling.

The sizing bevel gauge graduated, which carries an adjustable stop screw so that work may be ground accurately to size and duplicated.

The angle plate for free hand cornering of thin work.

The work table top has a groove paralleling the face of the grinding disc, and the work table attachments slide in this groove. These attachments are shown on floor and on work table in Fig. 1.

The drum sanding attachment has a work table 24 ins. x 28 ins., which may be tilted and locked at any angle from 85 degs. to 105 degs. from axis of sand drum. Large, distinct graduations are provided to indicate the angular adjustment. The sand drum shown is 2½ ins. diameter by 12 ins., long, but drums from 1 in. to 6 ins., diameter of any reasonable length may be used. The work table has a central angular opening 8½ ins., diameter into which are fitted circular plates with center holes to accommodate drums of various sizes. The sand drum runs at 2,250 r.p.m. and is given a vertical reciprocating movement, while running, to equalize the wear on abrasive. This movement is adjustable from 0 to 4 ins. A self oiling friction clutch coupling is provided between grinding spindle and drum sanding attachment to enable operator to stop the drum sander regardless of the disc wheel.

Fig. 3 shows an improved motor drive for the machine, this form of drive having, the makers state, proven more satisfactory than gears or silent chain. A standard motor, equipped with belt tightening attachment is mounted on an angle plate at back of a standard belted grinder, and the drive is through endless leather belt as shown. The motor is of 3 h.p. intermittent rating, and it will be noted that an extra wide belt is used to prevent slippage due to fine wood dust getting on pulleys.

The following general specification indicates a few additional features concerning the capacity and scope of the grinder:

Disc wheel 30 or 40 ins. diameter by ¾ ins. thick.

Spindle pulley 12 ins. diameter for 6 ins. belt.

Spindle 2½ ins. diameter by 37¾ ins. long.

Length of each bearing bushing 8 ins.

Diameter of work table post, 4 ins.

Height to center of spindle, 38 ins.

Floor space of bed casting, 30 x 42 inches.

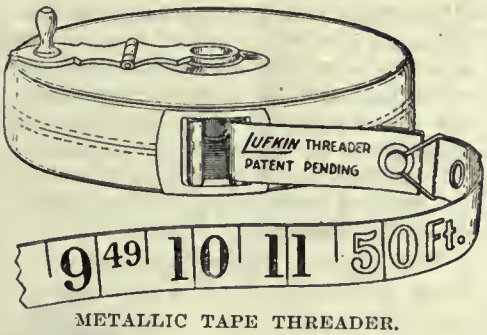
Operating floor space for machine, 8 ft. x 12 ft.

Shipping weight, motor driven 3,000 lbs.

METALLIC TAPE THREADER.

THE Lufkin Rule Company of Canada, Ltd., Windsor, Ont., have recently put out a patented measuring tape attachment, known as a Threader, which will hereafter be furnished with their metallic woven tapes without extra charge. The threader is a loop and stud arrangement, by means of which the tape, though securely fastened to the winding drum of the case when in use, can yet be readily detached from it and a new tape as readily attached, no manipulation of the case, case screw or drum being required to do this.

Woven tapes are sometimes torn by



METALLIC TAPE THREADER.

accident or through long use often become soiled and worn in such a way that they must be replaced while the case is yet in very fair condition. The line usually outwears it, and representing approximately half of the value of the outfit it is of considerable importance that it be a simple matter for anyone to insert a new tape in the old case as often as necessary and thus get the fullest measure of use out of the case as well as the tape. Metallic tapes without cases are quite generally stocked by supply houses, etc. ,and can always be easily obtained. Attachment is perfectly and easily accomplished by means of the threader.

A NEW HIGH TEMPERATURE CEMENT

A NEW high temperature cement recently placed on the market by the H. W. Johns-Manville Co., New York, is so composed that it vitrifies at as low a temperature as 900 degs. F., and withstands 2,760 degs. F. before melting. At 1,500 degs. F. is has a carrying capacity of 2,030 pounds per cubic inch, indicating especially high mechanical strength.

This new cement—the latest of several high temperature cements produced by this company to meet different conditions within recent years—is claimed to be adapted for comparatively low temperature furnace work. It is especially recommended for building door jams and lining doors in low temperature furnaces and as a fire-brick for repairing and patching parts of low temperature furnaces; building stoker gates in water tube boilers, building baffle walls; lining covers of brass melting furnaces, incinerators and hardening furnaces; building dampers of incinerators, and as a firebrick mortar for repairing and patching doors in re-heating and glass annealing furnaces subject to severe abrasion. J-M No. 26 cement can be applied to gas retorts for patching while they are hot.

There are many conditions under which it is necessary to surround iron bars with a refractory material and this new cement admirably fulfills the requirements, particularly in the construction of annealing furnace doors, which are usually of very large dimensions, and where it is necessary to use vertical and horizontal bars as a reinforcement to the frame. This cement used in conjunction with cushions of asbestos paper around the bars has been found very efficient for this purpose.

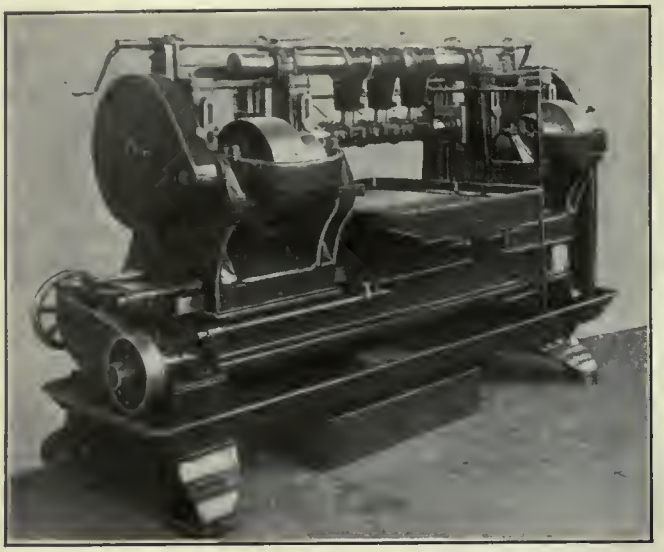
HENDEY DUPLEX LINCOLN MILLER.

THE illustrations show the size No. 16 Duplex Lincoln Miller of extra heavy design made to meet the most exacting demands of high speed production, by the Hendey Machine Co,. Torrington, Conn. The bed is massive and has extra wide top surface with square lock for supporting and aligning headstocks and saddle. The main spindles have taper journals on front end running in annular bearings lined with Lumen metal. The spindles have No. 12 Brown & Sharpe taper hole in front end with threaded nose, and an arched bar is cast integral with power shaft bearings, thereby helping to maintain their alignment on guides, and also acting as a belt guard.

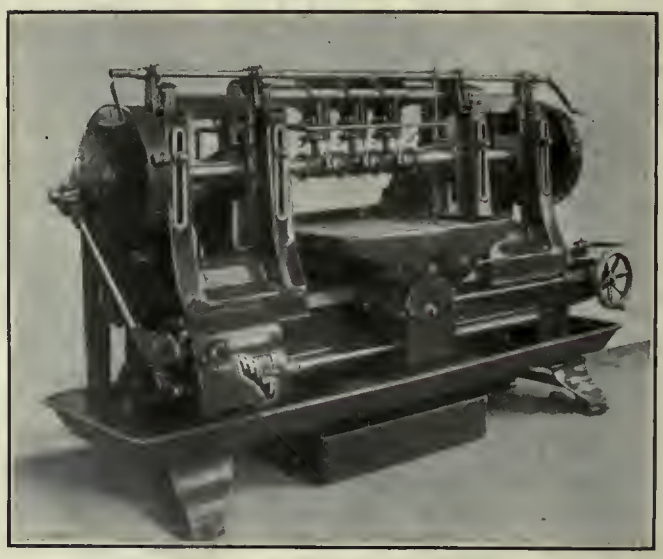
Heavy connecting links serve to tie the power shaft and main spindle bearings together, two links being applied to each head for automatically controlling the engagement of gear train in the spindle drive, no matter what elevation may be given to spindles. The gears are fully encased by guards which have compression grease cups for lubrication of gears. The spindles have unit control for elevating in unison. The overhead

arm or tie bar has three pendants for arbor support, and fitted with split bearings hinged, so that the bottom half falls away to facilitate quick removal of arbor. The table is fitted with power quick return, being geared for an approximate speed of 100 ins. per minute. It also has high sides for confining cutter lubricant.

This machine when fully equipped with fixtures and cutters for manufacturing operations is capable of a high rate of production. It is made in different lengths of bed, and is furnished with tables of different working dimensions. It can be had with or without oil pan, pump and piping equipment as desired.



HENDEY NO. 16 DUPLEX LINCOLN MILLER.



HENDEY NO. 16 DUPLEX LINCOLN MILLER.

SYSTEMS OF COKE OVENS.

THE July issue of the Revue de Metallurgie contains an extensive study of the principal systems of regenerative coke ovens, by M. Charles Berthelot, chiefly concerning their stability, and their economic applications. The points considered include the obtaining of the maximum coke yield, the maximum yield of by-products, the quality of the gas, and the solidity of the design of the oven. The ovens examined consisted of:—

(1)—Recuperative ovens, Solvay type.

(2)—Longitudinal regenerators in parallel, Otto, Collin, Still, Piette, Simplex, and Carves.

(3)—Longitudinal regenerators in series, Coppee type.

(4)—Transverse regenerators in parallel, Koppers.

(5)—Transverse regenerators in series, Lecocq.

The various furnaces are examined at considerable length, and note is made of the great increase in variable surplus gas by the introduction of regenerative ovens.

NEW SUCTION LUBRICATOR

A NEW and novel lubricator, made in three sizes for ¾-in., 1-in. and 1½-in. pipe connections, for use particularly on devices operated by compressed air, has just been brought out by the Vulcan Engineering Sales Co., Chicago, and is illustrated in the accompanying cut. The principle involved is one of suction. A chamber containing an absorbent is kept saturated from large oil storage chamber surrounding it, and air passing through the lubricator becomes sufficiently charged with oil to properly lubricate all surfaces with which it subsequently comes in contact.

This device is entirely automatic, because suction action takes place the instant air moves, and it ceases immediately the air is shut off. The take-up of oil is extremely moderate though continuous when air is being used. The apparatus can be attached to the air line in any position and operates in any plane or at any angle and can be filled in no matter what position. It is claimed, therefore, to be universal and fool-proof, and likely to prolong the life of pneumatic equipment, besides conserving the amount of lubricant used, thereby increasing efficiency and reducing maintenance costs.

NEW STYLE SUCTION LUBRICATOR.

A NEAT ELECTRIC SWITCH.

THE Duncan Electric Co. of Montreal have placed on the market a new line of standard electric fixtures. Their policy has been to simplify the various pieces, the new rosettes, sockets, extension plugs, switches, etc., being planned to give the least possible trouble to wiremen.

The latest addition to the list is a switch which when connected up is flush with the wall. Through a neat little rectangular-shaped brass plate a small brass lever extends, on the end of which is screwed a spherical brass ball; the switch being operated by throwing the lever up or down. The features of the switch are its ornamental flush mounting on the wall and the simplicity of its parts. The little switching lever is insulated from the current by the introduction of a porcelain link in the operating levers.

FLUSH WALL SWITCH.

LABOR'S ANNIVERSARY DAY.

A FEATURE of the many Labor Day gatherings was the whole-hearted loyalty expressed towards our Empire in its fight for a world-wide freedom from the dual curse of autocracy and militarism, and the determination to aid in accomplishing the desired end by giving of themselves and their substance. The world to-day owes much to organized labor, although bubbling-over enthusiasm has been responsible for a number of excesses, yet it should not be forgotten that much of the civilization and liberty we now enjoy and hold as sacred as life itself, were in their initial stages marred by afterwards regretted excesses.

BUSINESS DEPRESSION A 20TH CENTURY SCANDAL.

THERE is a growing disposition on the part of the general public to investigate for themselves the recurrence of periods of business depression and to ignore the abstruse and for the most part unphilosophic utterances and declarations of self-styled financiers. Business depressions both on account of their almost measured regularity and of their severity are positively a 20th Century scandal, and thanks to the cultivation of a higher degree intelligence among the great mass of our people, and therefore a minimizing of the tendency to be led and directed blindly by a self-elected few whose judgment and capacity in the matter of handling a nations' cash resources has never exceeded normal, there is a prospect that the old regime and old order of things are destined for replacement.

The trouble with business enterprise to-day in Canada is that it is not being financed by our banks as it ought, and until a race of men who have been reared outside of the antiquated confines of a Canadian banking system displace the sleek, smug devotees of a tight-lidded cash-crammed chest, the needful relief will not be forthcoming. Canadian bankers are reared to a system which is equally inflexible as the law of gravitation, and while initiative, genius, discovery and progress have marked most other trades, professions and institutions, the business of banking may still be summed up for the most part as a species of what-we-have-we-hold.

Much loose talk is being indulged in with reference to establishing a Canadian moratorium in whole or part, and to conserving the interests of depositors. At the same time, much of this gossip is more or less inspired, which leads us to say that it is quite apparent our bankers have added to their other superfluous attributes that of being panic-stricken. No wonder is it that our factories and industrial establishments are being put under the ban, and that too at a time when opportunity is knocking loudly at their door. Further, why this unnatural because uncalled for conservation of and concern for depositors' interests? The dissemination of news relative to the latter feature, and the dangling of a probable moratorium establishment are just such things as will bring about a money panic and a run on our banks by depositors.

There will be no need to worry about depositors withdrawing their savings, if our banking institutions will but be enterprising and loosen up so that the business we have had all along be followed in a normal way, and the splendid opportunities we now have of extending it be reasonably taken advantage of.

We are informed that our banks were never so well fixed in the matter of cash resources, in spite of the fact that our people have their stockings in process of filling in their homes. This time-worn tale we note is again doing duty, but as on many former occasions the laugh is on the bankers.

Banking reform of all others projected is the most urgent in this Dominion of Canada to-day, and only its bringing about will draw progressive men to dispense its provisions. The riot and excess of speculation and illegitimate enterprise financing and the throttling of our commercial life with its attendant hardship and misery which we have become accustomed to in their periodic alternation will then, and only then, under capable direction and appreciation of our nation's needs, approach to and maintain a standard which will fluctuate little either side of common-sense par.

Machinery Display at the Canadian National Exhibition

Staff Article

Although perhaps more so than in recent years, a bigger change in the personnel of exhibitors of machinery and general mechanical engineering equipment falls to be noted, the Machinery Hall is as usual crowded, and the various other locations and departmental sections easily maintain the reputation of former displays. Our machinery manufacturers are to be congratulated on the enterprise they have shown in fostering the country's industrial wellbeing.

THE display in the Machinery Hall at the Toronto Exhibition is quite up to the usual high standard, a fact at once gratifying to those who are interested in this section of our National Show. It was anticipated by many that the present unsettled conditions in the industrial world would adversely effect the machinery exhibits, but this fortunately is not the case. All the available space is occupied and the exhibitors are showing an enthusiasm calculated to reform the most confirmed pessimist. That the majority of exhibitors are looking for good times ahead is reflected in the character of the exhibits. Many of the old familiar names are to be seen on the signs above the booths, although a number of former exhibitors are to be noted as missing on this occasion, their places have, however, been taken by others. The need for a new Machinery Hall becomes each year more apparent and most pressing, and while it is hardly to be expected that the authorities will do anything before at least another year has passed, the first favorable opportunity should be grasped. Several exhibitors complained to our representative of the roof leaking, causing thereby discomfort to those in line of the shower bath.

Among the Exhibitors.

Among the time honored exhibitors are to be seen the A. R. Williams Machinery Co. at the old stand, with their usual extensive display of tools. The Canada Machinery Corporation have the same location as last year and are exhibiting a line of new tools, among them being an all-geared head lathe and a radial drill. In the next booth is the exhibit of Corvan & Co., consisting of an interesting line of woodworking machinery. The Preston Woodworking Machinery Co. have increased their space this year and are exhibiting a number of high class machines.

The chapman Double Ball Bearing Co., are located in the center of the Hall and are also showing a new line this year in the form of an elevating truck for warehouses and factories. The utility of this truck is obvious after witnessing a demonstration. Close by is to be found the Dodge Mfg. Co. who are exhibiting a complete line of their well-known transmission appliances.

Among the new exhibitors, perhaps the most striking is that of the Victor Saw Works, Hamilton, Ont. This company occupy a booth at the east end of the Hall and have an effective display of Victor saw blades. The various stages of manufacture are featured on a board, while other displays show the different sizes produced, each being accompanied by a statement setting forth the particular work for which it is best suited. An interesting feature is a number of specimens of alloys used in the steel from which the saws are made. An arrangement of photographs and flags with a globe in the center illustrates graphically the world-wide use of Victor saws.

To the tired visitor, the booth of the Wilt Twist Drill Co., will be specially welcome. Here lounge chairs have been

VIEW OF GROUNDS AND LAKE, CANADIAN NATIOAL EXHIBITION.

provided for all those who care to avail themselves of the opportunity, of being able to learn of the company's product under comfortable conditions. The Pratt & Whitney Co. are new exhibitors this year and are showing their well-known lines of drills, reamers, etc. A booth attracting many interested visitors is that of the Carter Welding Co., who are demonstrating an Oxygraph machine. This mechanism, which is similar to a pantograph will cut steel plates, with an oxy-acetylene flame, to any desired shape. Welding broken castings with a Davis–Bornonville oxy-acetylene outfit also forms part of the exhibit.

Over the way is the booth of the L'Air Liquide Society also demonstrating the efficacy of the Oxy-Acetylene system for welding and cutting. Various samples of work done by this process show the high standard of attainment possible, also the many kinds of work that this apparatus is capable of overtaking. The company have on view a power or hand-welding machine, also a hand welder.

An interesting machinery exbibit is that of the Canadian Fairbanks-Morse Co., in the Agricultural section. Here are to be seen stationery and marine oil engines, while in an adjoining tent is a complete 25-bag flour mill in operation. The wheat is seen being passed through the mill to make flour and finally bread, etc., all in one tent.

The W. D. Beath Co.'s exhibit of runways attracts considerable attention as do also that of the General Fire Extenguisher Co., who were demonstrating the Grinnell head. Baines & Peckover have an extensive display of steel products.

Exhibitors, Exhibits and Representatives

Canadian Tool Steel Co., Toronto.—Picks, blacksmiths' tools, hammer heads, etc., made of Ductite steel; also the Dickson patent wrench. Representatives: R. I. Henderson, Fred C. Fowler.

Carter Welding Co., Toronto.—Davis-Bournonville Co., oxy-acetylene welding outfits. Demonstrations with oxygraph cutting machine. Representatives: W. Carter, H. W. Carter and P. Sorley.

Canada Machinery Corporation, Ltd., Galt, Ont.—Wood working tools, consisting of chain morticer, 24-in., planer, matcher and molder; tenoning machine with cut-off saw; 12-in. molder; iron working tools consisting of a 20-in. x 10 ft. all geared head lathe; 27 in. x 16 ft., LeBlond lathe, and 4 ft. radial drill. Representatives: W. Baird, N. Blain, W. Irving, R. Dryden.

Canadian Ice Machine Co., Toronto.—Refrigerating plant in operation consisting of a 2-ton York machine, double pipe condenser, freezing tank, etc.; parts of a 4-ton York machine showing general construction. Representatives: C. E. Allison, C. H. Bower.

Canada Hart Wheel Co., Hamilton, Ont.—Complete line of abrasive wheels, razor hones, etc., and saw sharpening machine. Representative: F. S. Morrison.

Cowan & Co., Galt, Ont.—Two chain saw morticers, vertical hollow chisel morticer, 6 in., four side molder, power feed rip saw, surface planer with round cylinder grinding and jointing attachment. Representatives: W. Cowan, S. F. Barrows.

Consolidated Elertric Co., Toronto.—King Edward electric motors, ½ to 25 b.p.; electric fittings, conduits, switches, etc. Representative: J. G. Howorth.

The Canadian Fairbanks-Morse Co., Toronto.—Exhibit in agricultural section of gasoline engines, direct connected pumps; various sizes of 2 and 4-cycle marine oil engines up to 25 h.p.; pneumatic water systems. Representative: R. B. Dargavel.

Climax Good Roads Machine Co., Hamilton, Ont.—Climax hand balers in two sizes for 200 and 100-pound bales respectively. Representative: H. Robinson.

Commercial Oil Co., Hamilton, Ont.—Full line of oils and greases; special transmission grease; liquid and stick belt dressing; complete line of Sharp spark plugs. Representatives: A. W. Houlding and F. C. Walsh, with J. M. Mackenney, representing the Sharp Spark Plug Co., Cleveland, Ohio.

Canada Metal Co., Toronto.—Complete line of Babbitt metal, heavy pressure bearing metal, solder, lead pipe and ingot metals, also plumbers' supply department fully equipped. Representative: W. G. Harris, W. G. Harris, Jr.

Dominion Belting Co., Hamilton, Ont.—Maple Leaf stitched cotton duck belting for power transmission and conveyors; belt dressing. Representative: J. Scott.

W. D. Beath & Son, Ltd., Toronto.—Demonstration of overhead industrial tracks and runways.—Representative: W. D. Beath.

The Canadian Morehead Mfg. Co., Woodstock, Ont.—Morehead line of steam and condenser traps. Representative: E. J. Bickle.

The Canadian General Fire Extinguisher Co., Toronto.—Automatic sprinkler fittings, steam supplies, Chapman valves, Grinnell heads, automatic sprinkler demonstration Representative: C. H. Burt.

The Dodge Mfg. Co., Toronto.—Complete line of transmission machinery, including steel and split wood pulleys, bearings, hangers, etc. Representative: J. F. Haas.

The Chapman Double Ball Bearing Co., of Canada, Toronto.—Complete line of ball bearings up to 6 7-16 in. power and hand operated efficiency testing plants. Friction clutches, thrust bearings, etc. Elevating truck for factories and warehouses. Representatives: W. J. Murray, Chas. Murray, J. B. Wilson and W. C. J Hockin.

British Aluminum Co., Toronto.—Full line of aluminum producta. Representative: E. Fannell.

Cleveland Pneumatic Tool Co., Toronto.—Full line portable pneumatic drills, grinders, sand, rivetting and chipping hammers, rock drills, Bowes and Never Leak couplings, etc. Representatives: J. A. Day, C. O. Garner.

General Machinery Co., Toronto.—G. M. C. automatic water systems; demonstration of Luitweiler pumps. Representative: W. McLachlan.

Galt Foundry Co. Galt Ont.—Demonstration of the McNaughton Grate. Representative: F. W. Donaldson.

The Boiler Repair & Grate Bar Co., Toronto.—Demonstration of shaking grate. Representative: A. H. Hett.

The Elliot Woodworker, Ltd., Toronto.—Demonstration of the Elliot woodworker. Representatives: F. Elliot, G. Elliot.

The Jones & Moore Electric Co., Toronto.—Full line of Century electric motors. Representative: W. Dalton.

R. A. Lister & Co., Toronto.—Demonstration of a Lister-Bruston automatic 60-light plant and a 5 h.p. oil engine operating. In the agricultural section are a number of oil engines adapted for farm work, also Melotte cream separators. Representative: L. Burbidge.

D. K. McLaren Co., Montreal.—British Oak Tanned Belting, D.K. Balata Belting, Philips pressed steel pulleys, D.K. wool aplit pulleys and general line of mill supplies. Representative: W. S. Hamilton.

J. L. Morrison & Co., Toronto.—Bookbinders' and printers' machinery. Representative: W. Doldring.

The Massey-Harris Co., Toronto.—A number of gasoline engines in operation, pumping outfits, power sprayer, etc. Representatives: B. Graham, N. A. McIntosh.

The National Equipment Co., Toronto. —Peerless automatic water systems for domestic purposes, and demonstrating a 125-gallon per hour pumping outfit; also an exhibit in the Transportation Building of the Wayne Gasoline and Oil Storage Systems. Representative: W. T. Bradley.

The Nash Temperature Control, Ltd., Toronto.—Nash automatic controlling devices for ings. Representative: J. M. Watson.

The Schaeffer & Budenberg Mfg. Co., Brooklyn, N.Y.—Display of indicating and recording gauges, indicators, tachometers, pyrometers, etc. Representative: Curt E. Georgi.

The L'Air Liquide Society, Toronto.—Demonstrating oxy-acetylene welding; hand or power welding machine for boilers, tanks, etc.; hand welding machine for light work, acetylene generators and numerous specimens of work. Representatives: J. Macmillan, T. Girouard, G. Cooper.

The Pratt & Whitney Co., Dundas, Ont.—Display of P. & W. twist drills, reamers, taps, dies, and milling cutters; also a 10 in. tool maker's lathe. Representatives: J. D. Dixon, Webb.

Preston Woodworking Machine Co., Preston, Ont.—Belt sander, power feed saw, 12 in. molder, 36 in., band saw, 24 in. panel planer, 36 in. high speed ball bearing shaper and Newport attachment for molding machines. Representatives: W. J. Murray, W. E. Near.

The Siche Gas Co., Toronto.—Oxy-acetylene welding and cutting plants, Siche gas for lighting, Oxyweld for welding, Allan-Liversidge acetylene generators for automobiles, etc., acetylene heaters and stoves. Representative: L. R. Arnett.

The Victor Saw Works, Ltd., Hamilton.—Victor hand frame and power hack saw blades. Display of saw blades showing different stages in manufacturing, and alloys used in making saws; rail cutting frame with clamps. Representatives: C. O. Yackman, W. S. Pollock.

Wilt Twist Drill Co., Walkerville, Ont.—Complete exhibit of Wilt twist drills and reamers. Representatives: W. A. Tingle, H. K. Clark.

The Holden Co., Montreal.—Complete line of portable electric and air tools, rock drills, and railway supplies. Representative: J. B. Wilson.

The Garloch Packing Co., Hamilton.—Full line of Garloch packings and Keystone grease. Representative: N. G. Davis.

The Arnold Co., Toronto.—The Arnold Automatic Fuel Economizer.

Baines & Peckover, Toronto.—Line of Saville's tool steel, Triumph Superb; crucible, vanadium and cold rolled steel; expanded metal, babbitt metal, chain, wire rope, etc. Representatives: W. M. David, T. A. Steven, H. W. Marshall, A. McGregor, W. P. Williams.

Cling Surface, Buffalo, N.Y.—Belt treatment, demonstration showing high efficiency of slack belts with Cling Surface. Representative: J. A. Faatry.

S. F. Bowser & Co., Inc., Toronto.—Exhibit in Transportation Building: Gasoline and lubricating oil systems, Red Sentry pump for automobile, curb filling stations. Process Building: Lubricating oil systems, filtering systems, etc. Representatives: R. W. Williams, A. McIntosh, A. E. Moffatt, E. T. Murphy, and H. T. Stern.

Belt Grip Pulley Co., Buffalo, N.Y.—Leather-faced pulleys for high-speed drives, leather castors. Representatives: A. E. Finch, C. G. Hurlburt.

H. F. McIntosh & Co., Toronto.—Sales agents for Star expansion bolts. Representatives: M. McIntosh, W. J. Stacey.

J. J. Martindale, Toronto.—Demonstration of the Tuec stationary vacuum cleaner for office buildings, residences, hotels, etc.

The Prest-o-Lite Co., Inc., Toronto.—Prest-o-Lite for automobiles, motor boats, etc.; compressed acetylene for lighting, welding, etc. Representative: H. R. Weckerle.

Mackintosh Hutchinson, Toronto.—Demonstration of the Hutchinson portable combination woodworker with dado, ripping, crosscut and boring attachments in two sizes, with 1½ h.p. and 3 h.p. motors respectively. Representatives: M. Hutchinson, H. Trevett.

The Positive Clutch & Pulley Co., Toronto.—Demonstrating the positive combined jaw and friction clutch, heavy duty combination pulley, all-steel pulley and wood split pulley; gas engine friction clutch. Representative: R. A. Fraser.

A. R. Williams Machinery Co., Toronto.—Le Blond 17 x 8 heavy duty lathe, Barnes 24-in. drill, Harper planer, Famous woodworker, Drummond foot-power lathe, Warner & Swasey universal turret lathe, Brown & Boggs press, Perfect emery grinder, Morris 1-ton worm gear chain block, Lennox throatless shear, Evinrude gasoline engines. Representatives: T. Reid, E. C. Cronk.

B. B. Kelliher, chief engineer of the G. T. R. has sent in his resignation on account of ill-health. Mr. Kelliher has been engaged for fifty years on railway construction.

The General Market Conditions and Tendencies

This section sets forth the views and observations of men qualified to judge the outlook and with whom we are in close touch through provincial correspondents.

Montreal, Sept. 7, 1914.—Conditions have undergone a slight change for the better during the past week. A great deal of excellent work has been done by the press in educating the people to appreciate the importance of the great wave of industrial prosperity which may soon overtake Canada. However, the seed has largely fallen on barren ground as yet, for there are many yet to teach and enlighten. Consternation reigned supreme in business circles during the opening days of the war, and those men who were then panic-stricken are now more or less ashamed of themselves. Their mistake has taught both them and their neighbors a wholesome lesson. Thus it is seen in business circles that conditions are gradually improving. The Government at Ottawa is arranging matters so that both the Grand Trunk Pacific and the Canadian Northern Railways will be able to obtain the necessary cash against the country's guarantee, while the City of Montreal has made most favorable arrangements with the Bank of Montreal for its finances during the next five years. The financing of the Western wheat crop has been a source of much speculation, but it is now understood that arrangements have been completed and the banks have extended practically the same lines of credit as were in existence last year. All these actions on the part of the banks and the Government seem to have had a great influence on the spirit of the people generally. Of course, it cannot be denied that trade is still in a demoralized condition, even although a decided improvement in the general complexion of business is noticeable. There is no doubt now that the allies are slowly, surely, and irresistibly weaving their net around the enemy, and soon our forces will be ready to strike. When the blow falls, a crisis in the history of the world will have been reached, and Germany as a factor among the powers of Europe will cease to exist.

Steel Market.

Little or no change has taken place during the last week. Prices have scarcely moved, and sales have been very light indeed. There is, however, a pretty general feeling that the steel business will shortly pick up and continue to improve gradually, if slowly.

Pig Iron.

The market in pig iron has been very slack. Prices fluctuate little, the trade in British pig being practically nil.

Machine Tools and Supplies.

The outlook for machine tools is still unimproved, although those houses dealing in supplies as well as tools still report a fairly large number of sales. All are of the small variety, and the total does not represent a very great turnover.

Metals.

The metal market seems to be holding its own. The sales for the week are not large, and the prices remain the same. Tin is the only metal whose probable change in price is looked for.

Toronto, Ont., Sept. 8, 1914.—Business conditions, generally speaking, are unchanged except that perhaps a more confident spirit exists than has obtained since the outbreak of hostilities. This however, may be caused by the fact that we are getting more accustomed to the situation. A spirit of caution prevails, but as time passes that will be relaxed, and being a natural sequence of the war, if not overdone, is to be commended. One thing to be feared is an excess of caution accounting almost to a scare, which is to be avoided at all costs. Manufacturers are becoming more accustomed to prevailing conditions, and are beginning to realize that while trade may be restricted in some lines for a time, there are possibilities for expansion in other lines.

The advantages that will accrue to Canada on account of the war will only be known after a full investigation into the possibilities of developing trade, both home and export. There are many points to be considered, and it is too early to say what lines are most likely to be developed. That fact that the Department of Trade and Commerce, and in addition several Boards of Trade, propose to make determined efforts to secure trade in markets formerly held by Germany, augurs well for the industrial development of the Dominion in the future. A great opportunity is before the country; let, therefore, full advantage be taken of it, and no time be lost in availing ourselves of the conditions with which we are confronted. Our friends over the border are alive to the opportunity, and will be quick to take full advantage. A strong effort should therefore be made to capture all the foreign trade that it is possible to obtain.

The spirit emulating the exhibitors in the Machinery Hall of the Canadian National Exhibition now being held here is well worth noting. Notwithstanding the temporary depression in the trade, these concerns have exhibited at considerable cost, in many cases without hope of immediate return, but all confident of the future. There is no panic at the Exhibition this year, bnt instead a general feeling that business will be good in Canada as soon as conditions become settled. Firms carrying on business in this spirit will be the first to benefit when the psychological moment arrives. With the above in mind, it is to be earnestly hoped that manufacturers will keep their factories running to the fullest extent possible, for by so doing they are rendering the country a national service.

Steel Market.

No change is to be noted in the iron and steel markets this week; business is quiet in most products, as customers are waiting until the situation becomes clearer, and the money market easier. The effect of the war on the steel trade is pretty well realized so far as it concerns present markets, the net result being that steel producers have been obliged to curtail operations. The difficulty is not so much a question of obtaining raw material as in finding a market for the finished products. The home market is very quiet and is likely to remain so until conditions improve generally. The difficulty of financing projects is one of the chief reasons for the falling off in the home demand. Because of the latter, strenuous efforts will be made to obtain new business, and already the Dominion Steel Corporation has sent a representative to the Old Country to investigate opportunities for trade with English markets. This is the forerunner of a general movement to investigate the possibilities of extending our export trade.

It is reported that the C.N.R. will now be able to obtain in London, part, if not all, of the money guaranteed by the Dominion Government, in which case the work will be proceeded with according to the original programme. The disbursement of such a large sum of money, at such a time as this, will be extremely beneficial to a considerable section of the community. The fact that the money can be obtained at the present juncture should have a reassuring effect in financial circles. The Ontario Government has formulated a scheme whereby a considerable sum of money will be expended this fall and winter, in making and improving public highways. This also will help the labor situation, which may be serious later on in the year.

Prices on steel products have not changed. The United States Steel Corporation has recently received a number of orders for foreign account, attributed to the war, while several enquiries have been received by U. S. mills for export tonnage. The ferro-manganese situation is about the same, although there appears to be a possibility that the British Government will prohibit the export of this metal, and so cut off one of the principal sources of supply.

Pig Iron.

The pig iron market is quiet, both consumers and producers waiting for an improvement in the outlook. Such buying as there is being done, is only to satisfy immediate requirements and generally in small quantities. Prices have not changed.

Machine Tools.

Business is light, dealers reporting few sales. Quite a number of machine tools have in the past been imported from Germany, and the fact that this market is now cut off, should help Canadian concerns, and encourage them to develop these lines, thereby increasing their home business with a prospect of developing an export trade. Importers of English tools are not experiencing any difficulty in filling orders.

Machinery Supplies.

Business in machinery supplies is quiet, and prices generally are unchanged. There will be little improvement in the supply business, until conditions are more settled, and machine shops are more active.

Tool Steel.

There is not much demand for tool steel at the present time, the situation having undergone little change.

Metals.

The metal markets are quiet, consumers only buying for immediate requirements, and then usually in small lots. The price of tin has weakened, although the situation has not improved, it being just as serious with regard to obtaining supplies from abroad. All other metal markets are steadier, and there has been no change in prices.

THE BRITISH SPIRIT IN BUSINESS.

IT is not merely in the field of battle that the British people face the great issue without panic and without fear. There are industrial battles which require pluck and nerve and generalship as great as are expected of the men upon active service. Sir Algernon Firth, president of the Associated Chambers of Commerce of Great Britain, speaking recently at Bradford of this aspect of the stern conflict before the nation, said he had been asked his opinion as to the formation of distress committees.

Speaking for his locality and Yorkshire, he said they did not want distress committees at present. What was wanted was continued employment for the people. Full employment could not be expected, but if partial employment for three or four days a week could be provided there was no need for starvation. As employers they could not expect to come out without loss, but they had got to suffer their loss like men and stand their corner.

The position at the present time was that the Government had agreed to extend the national credit and responsibility to support the bankers, who in their turn would support the business men in finding employment for the population. Business men could, if they desired, stop their works, remove themselves to a safe haven, and leave their workpeople to their own devices, but that was not what they in Yorkshire were going to do. They were going to stand by the workpeople and continue the industry.

There speaks the Briton with his bulldog tenacity and his sense of human brotherhood. The factory gates will stand open so long as the manufacturers can find markets anywhere for their products. They will forego profits rather than see their workmen dispersed and left to shift for themselves. In Canada, our captains of industry can best show that they, too, are of the true British breed by devoting all their thought and energy not to hunting safe places wherein they and their hoarded wealth may find shelter from the storm, but to fighting the battle of industry with courage and fortitude and bringing those under their keeping safely through the crisis.—Toronto Globe.

TRADE AND COMMERCE RECORD

Dealing With the Steps Being Taken and Progress Made by Industrial Canada To Achieve and Maintain a Dominant Place in the Markets of the World

CANADA'S PAPER INDUSTRY.

THE international situation influencing the future of the news print industry in Canada continues to develop points of importance. Although few conversant with the condition of the Canadian paper market at the present time may feel elated by immediate prospects, the fact remains that the general course of events in this country and the United States, is playing strongly into the hands of Canada.

"A survey of the news print mills in the United States and Canada and some knowledge of the annual reports presented at recent meetings, bring out a fact of the most vital significance," says a pulp expert in discussing the situation.

"Those United States mills, which have been far-seeing enough to acquire abundant pulpwood limits, and are equipped with plenty of water power, which they can afford to use for mill purposes, and in addition are blessed with facilities for cheap water transportation are making some money, and probably will continue to, but there are numerous other news print mills, the directors of which face a perplexing situation.

1,000 Tons of News Print Per Day.

"First of all, the abolition of the tariff imposts on cheap papers, has encouraged Canadian mills to load the American market with 1,000 tons of news print paper per day. That enormous and increasing importation means a lowered demand for United States products, a position which the paper mill owner south of the border faces with helpless amazement, for however reasonable and emphatic his protests to Washington may be, the ear of Congress is not turned in his direction.

"During the past two years or more, many of the United States mills have sought to escape what was an obvious doom by altering their product from news paper to cheap book paper, but here again they encountered a branch of the industry already overcrowded to the point of disappearing profits. The last statement of the American Writing Paper Co., in which it was indicated that dividends would have to come from the available surplus, reflect a condition anything but encouraging to the news print maker contemplating a change of market.

Continuous Water Power.

The denuding of the forests throughout the paper manufacturing States has brought on another problem from which the Canadian mills escape. Twelve months of good water power per year is not at all unusual with the large Canadian companies, while seven months power is about the average south of the border. That means that for five months a year the American mill must buy pulp supplies from Canada or elsewhere, adding many dollars per ton to the cost of the output. Instead of improving with the years, this shortage of water during certain seasons has become more and more aggravated. Such a condition, of course, supplies a profitable market for Canadian exporters of ground wood, but even that advantage is being circumvented by the growing custom of Canadian limit owners to turn their raw material into paper and keep the big end of the profit in their own pockets.

British Capital in Control.

"British capital is master of the paper industry in Canada, but it can only be a matter of a few years until ventures similar to the Donaconna mills become quite common and American money shows itself alive to real opportunity.

"Three factors control the success or non-success of the pulp and paper mill:—Cheap and plentiful water power, abundant pulp wood supplies contiguous to the mills, and good transportation facilities. In all three, Canada holds the whip hand. Whichever of the great Canadian mills one cares to examine each item is seen to be present in remarkable degree. Laurentide, Price Bros., Booth's, Ontario and Minnesota, Spanish River, or any of the other big plants are in practically every case possessed of splendid water powers and continuous supply, good pulp limits, and first-class transportation by rail and water.

Conservation Laws.

"By improved conservation laws there can be no reasonable grounds to fear the same carnival of waste and carelessness that has reduced the pulp forests and water powers of the United States to such an alarming extent. With any sort of moderate care the chief assets of the Canadian mills should be made perpetual At all events Canada has awakened to the danger of extravagance in time to guard the bulk of her resources. In the United States, however—and this fact means everything to the future of the paper industry—the idea of conservation arrived half a century too late."

CANADA'S TRADE WITH COUNRIES IN WAR ZONE.

MAKING the returns of the trade of Canada for the twelve months ended April 30, 1914, it would appear that the war would only affect the Dominion's relations with Belgium, France, Germany and Holland. Canada should be able to continue a free trade with all other points as in other years. Canada's total imports for these twelve months from the four nations in the immediate war zone totaled $35,659,125, which represented only 5.7 per cent. of the total volume of her imports in that time. Total exports for the period were $19,406,282, which represented 4 per cent. of the total exports of the twelve months.

Trade in War Zone.

The figures with regard to this trade make the following comparison (being for the twelve months ended April in each year):—

Imports.	1913.	1914.
Belgium	$4,108,561	$4,377,154
France	15,460,129	14,026,037
Germany	14,295,819	14,465,080
Holland	2,149,898	2,790,854
Total	$37,014,407	$35,659,125
Exports.	1913.	1914.
Belgium	$4,663,884	$4,750,759
France	2,697,871	3,857,048
Germany	3,500,416	4,338,303
Holland	2,795,806	5,460,172
Total	$13,657,957	$19,406,282

While it is not certain that our trade with European countries other than Germany will utterly cease, it is evident that there will be a heavy contraction in the coming year from last year's figures. France, for instance, sends us $2,044,495 worth of spirits and wines alone. With France at war with Germany there will be a big decrease in her make of all wines and a consequent falling off in shipments to Canada as well as elsewhere.

Trade With Germany.

An interesting idea of Canada's trade with Germany is contained in the Government statistics. The latest statement available giving full details is for the year ended March 31, 1912. Total

exports for the year were $3,814,914, against imports of $11,146,746, demonstrating that the total trade between the two countries reached a volume of $14,961,660.

The Canada Gazette last week warned Canadians that no trade must be made with Germany at the present time. Thus it is manifest that our trade in this direction will absolutely cease for an indefinite period (at least until the present war comes to an end and peace is re-established).

The principal articles of export from Canada to Germany, according to the latest available blue book figures, are:—

Breadstuffs	$1,853,724
Fish	252,850
Furs	65,601
Agricultural implements	632,494
Iron and steel mfrs.	646,761
Miscellaneous metals, etc.	255,510
Oils	75,804
Sausage casings	8,579
Seeds	59,371

Articles Imported.

The principal articles imported from Germany, to the amount of $50,000 or more, were as follows:—

Clocks	$107,131
Cocoa beans, etc.	60,696
Combs	69,228
Lace	152,065
Socks and stockings	304,687
Cottons and mfrs., duty	687,966
do. free	43,757
Aniline and coal tar dyes	187,054
Potash	59,955
Drugs, etc., duty	125,552
do. free	386,622
Earthenware	295,672
Electric apparatus, duty	51,857
do. free	1,487
Fancy goods	929,641
Flax, hemp, jute, duty	48,321
do. free	5,590

LIGNITE IN SASKATCHEWAN.

THE plant which is now being erected at Estevan by the Saskatchewan Government for the purpose of testing the lignite coal of that district has been placed in charge of S. M. Darling, who has had experience of the work in North Dakota.

In this connection it is to be noted that the current issue of the Public Service Monthly, published by the Saskatchewan Government, contains a full report of the results obtained from the lignite of North Dakota, which is of the same character as the lignite of South Saskatchewan. The chemical composition of this lignite does not allow of its being successfully briquetted in its natural condition. To market the lignite commercially on a large scale, it must be destructively distilled, carbonized, or partially carbonized, and the resulting gas, oil, or tar, ammoniacal liquor and carbon residue, utilized separately.

By carbonization of the North Dakota lignite, the products, in round numbers, are:—gas, per ton of lignite, 10,000 cubic feet; oil or tar, 20 gallons; ammoniacal liquor, 35 gallons, and carbon residue, 1,200 pounds. The gas is of high heating value, and while containing a good percentage of illuminant, has about 15 per cent. of carbon dioxide, which almost entirely destroys the illuminating power. The carbon dioxide can be removed by passing the gas through lime, but the process is too expensive for commercial application. The gas can be used as an illuminant by mantle; but it is for fuel and power that its main available serviceableness can be made useful. The oil yields, on distillation, various light oils, benzine, etc., 36 per cent. of creosote oils and 22 per cent. of hard pitch, while the ammoniacal liquor yields several products for which there is a growing market, particularly in the case of sulphate of ammonia, as a fertilizer. The carbon residue, 1,200 pounds to the ton of lignite, can be briquetted, using 6 per cent. of the lignite pitch as binder. The briquettes burn with a short flame, no odor, no smoke and no clinker, and they can be used wherever anthracite or bituminous coal is burned. They retain their structure in the fire until completely burned, and do not disintegrate or lose value under the weather; they can therefore be shipped considerable distances without loss. The lignite coke is described as an ideal gas producer fuel, effecting a great saving over the present method of producing electricity by means of boilers and steam engines.

It is now an accepted fact among engineers that hydro-electric development in Saskatchewan is an impossibility. The rivers to the north carry so much silt and mud that the working parts of any turbine yet devised would be cut to pieces before the machinery could begin to pay for itself. The question of a large central power plant at the Estevan mines to generate electricity for transmission over a wide area is essentially one of the quantity of current that can be sold, the distance it must be transmitted, and evenness of load. If the current needs be transmitted a long distance to a large centre of population, there must be intermediate towns in which substantial quantities can be sold. It is simply a question of population. Of course, with cheap power, the population will come. Meanwhile, the immediate demand is for solid fuel.

PATENT PRACTICE AND THE WAR.

THE present war has naturally materially interfered with patent practice on the European Continent, and some time yet must elapse before points in doubt can be settled. We are, however, says Ridout & Maybee, patent agents, Toronto, in a communication to us, just in receipt of information from abroad of much importance to Canadian inventors or owners of Continental patents.

France has suspended indefinitely the requirement for the payment of taxes on French patents, so that all patents will remain valid until a future date, which will be set by special decree, and on which all arrears of taxes must be paid.

The German office has provided a general extension of time for three months from the 1st of August last for the filing of amendments to pending applications. This appears like a sublime confidence on the part of Germans in a short and successful campaign. Canadians having patent applications pending in Germany will not suffer, for the present at least, by the inability of their attorneys to do business in Germany, and if the war continues, further relief may be given.

The stories of the confiscation of British patents held by Germans and Austrians seem to be untrue. We have no official advices to that effect. It is not a probable course of action, as a government has the right to use any patented

inventions it may need, and also the right to set the compensation, but as the citizens of a country with which we are at war have no legal status in our courts, infringement would necessarily go unpunished. It will still be possible to do business with any European country with which we are not at war, but communication with such countries may be subject at times to delay.

SOUTH AFRICAN MARKET FOR PLOUGHS.

FROM the best information obtainable, says a U. S. consular report, it appears that 80 to 90 per cent. of the ploughs in use in South Africa are of the moldboard type. One of the most experienced American salesmen of agricultural machinery and implements stated that all through South Africa, just as in the United States, the particular type of ploughs best adapted to a given district depends entirely upon the nature of the soil. He emphasized the fact that certain ploughs made for use in the Southern section of the United States were found to be entirely unsuited to the soil in certain other States in the West. A practical mechanic, sent out by one of the large American concerns, says that, generally speaking, disc ploughs are suited to the soil of the Western part of Cape Province and all parts of Natal. He further stated that, also generally speaking, moldboard ploughs are best suited to the soil of the Orange Free States and the Transvaal. It is made clear, both by selling agents and practical mechanics handling American agricultural machinery and implements, that no hard and fast rule can be applied in determining what type of ploughs is best adapted to different parts of South Africa. In each instance the character of the soil in a given locality has to be taken into consideration.

Missionary Work Returns.

Those American manufacturers of ploughs who several years ago sent experts to demonstrate the good points claimed for their implements, and to remain in the country and watch the development of the business for several years in succession, have succeeded in building up a steady demand for their ploughs. It seems that very little advantage is to be gained simply by sending a salesman through the country on an occasional trip unless a really good practical man is left behind to follow up the work, supply spare parts for repairs, and to make helpful suggestions in cases where farmers are not getting satisfactory results, as well as to prevent competitors from unfairly undoing the pionees work which has already been done.

While the entire country has suffered lately from drought and labor disturbances, the consensus of opinion is that greater attention will hereafter be given, both by the Government and private individuals, to developing its agricultural resources. The carrying out of the irrigation projects now in course of construction or to be undertaken in the near future, will bring thousands of acres of land under cultivation which have heretofore lain idle. Both business men and farmers have come to realize that mining, hitherto the chief industry of this country, is a vanishing asset, and that the future of South Africa is wrapped up in its agricultural developments. Population considered, there is likely to be a growing demand for modern agricultural machinery and implements. The white population of the whole country is slightly over 1,200,000, but their per capita purchasing power is unusually high.

RUSSIAN IRON INDUSTRY.

THE iron industry in Russia has its principal centre in the Odessa district, and, therefore, it is principally this district which is affected by the increased activity in the mining of coal and iron in Russia. The state of affairs is such that it is now doubtful whether the Russian iron industry can cope with the growing demands made upon it by naval shipbuilding yards, railways, and engineering works. There has also been a renewal of house building, into the construction of which there enters an ever-growing quantity of iron and steel. The following figures show the output of pig iron, half-finished and finished products during each of the past five years, together with the estimated output for 1914:—

	1909. Tons.	1910. Tons.	1911. Tons.	1912. Tons.	1913. Tons.	*1914. Tons.
Pig iron	2,821,000	2,999,000	3,630,000	4,111,000	4,756,000	5,207,000
Half-finished products	3,079,000	3,482,000	3,885,000	4,433,000	5,110,000	5,594,000
Finished products	2,628,000	2,966,000	3,272,000	3,676,000	4,224,000	4,627,000

*Estimated.

A semi-official estimate indicates that from 2,400 to 3,200 miles of railway per annum for a series of years will have to be equipped with rails, quite apart from the demand for rails for repairs. This includes narrow gauge lines, though the ordinary gauge lines predominate largely. During the years 1909 to 1912, both inclusive, there was no particularly great activity in the construction of rolling stock, and on this account the demand is likely to be large for the next few years.

MOTORS FOR NEWFOUNDLAND FISHERMEN.

CANADIAN firms in a position to supply motor engines and motor fuel will find a valuable market is Newfoundland. The fishing fleet within the past two years has been installing motors in its boats, with the result that not only is there a brisk demand for engines but there is also a steadily increasing consumption of gasoline. Last year, according to statistical returns, motor engines valued at $140,000 were imported into the colony, and this year it is estimated that imports will approximate $500,000. The representatives of two United States concerns have spent the entire summer in and around St. Johns, and up to the end of July they had been able to place 275 orders. Engines of five, seven and nine horse-power composed the bulk of these orders, but in some instances higher powered engines were purchased. The prices for the smaller powered engines ranged from $180 to $225. So far as could be learned, no Canadian firm is actively engaged in soliciting this market. A few years ago a Nova Scotia concern, now in liquidation, sold a considerable number of motors. The two United States companies referred to seem to have largely gained control of the market. The fact that there is a rebate on the duty for engines for fishermen's use provides a stimulus for this trade.

In the matter of motor fuel, Canadian firms should be at a great advantage. Oil from the United States sells at 50 cents a gallon which is only 4-5 of an Imperial gallon. Gasoline in Canada can be purchased at 25 cents per gallon. As indicative of the demand, one fisherman requested one of the motor engine representatives from the United States to secure for him 50 drums of gasoline as an initial order. Inquiries for supplies of oil are also constantly noted in St. Johns.

Canadian firms in a position to supply either engines or fuel would do well to investigate the conditions in Newfoundland, for while the market for engines may not be an expanding one, that for motor fuel will steadily increase, and with the advantage of price in favor of Canadian concerns, a profitable business might be built up. Oil for the use of fishermen is also subject to a rebate of duty.

The Object.—The object of the average normal nation is to have more prosperity, to raise more taxes, to build more battleships, to seek more markets, to sell more goods; to have more prosperity, to raise more taxes, to build more battleships, to seek more markets, to sell more goods; to have more prosperity, and so on until something unforeseen happens.—Life.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News.

Engineering

Quebec, Que.—The Ross Rifle Co. will build an extension to its plant.

Quebec, Que.—The Masson Company will shortly erect a concrete and steel plant. Modern machinery will be installed.

Victoria. B.C.—Tenders have been received for the electrical, mechanical and heating equipment for the new Provincial Jail. J. C. M. Keith, architect.

Toronto, Ont.—The Board of Control have refused to reopen the contract for the high level station pumps and consequently it will remain with the Turbine Equipment Co.

New Liskeard.—The Wabi Iron Works Co. is running with their full staff in all departments, with every prospect of keeping their men busy. During the past week several large orders have been received.

Brockville, Ont.—The Warwick & Walters, Co., of Montreal, makers of gas and oil engines and accessories, are contemplating establishing a plant here. The company propose to rent an existing building and equip same with the necessary machinery.

Niagara Falls, Ont.—S. Austin & Sons, Cleveland, Ohio, are the general contractors for the new plant for the chain factory here, which is to cost $160,000. The building will be 150 x 440 feet, two-storeys high, of steel and reinforced concrete construction.

Prince Rupert, B.C.—An enterprise, which will mean much to the industrial life of Prince Rupert, made its first important advance on August 28, when the first of a series of twelve pontoons of the big 20,000-ton floating dry dock of the Grand Trunk Dock and Ship Repair Co. was floated. The next pontoon will be launched this month.

Toronto, Ont.—The war, while checking Canadian industrial enterprises generally, is at the same time helping to establish armament firms in Canada. The Canada Gazette of last week contains notice of the incorporation of the International Military Equipment Co., of Toronto, with a capital stock of $100,000. The incorporators include: C. McL. Moffat, army officer; Joseph Doust, stationer; W. R. Haile, financier, and S. B. Dawson and F. J. Stanley, brokers.

Redcliffe, Alta.—The plans and specifications for the building which the Imperial Brass Co. of Chicago will erect here for use as a brass factory, have arrived and may be seen at the office of H. O. Wheeler by contractors who may contemplate figuring on the contract. It is understood that the plans and specifications call for a building to which an addition may be added at any time.

Electrical

Peterborough, Ont.—The city will proceed with the hydro-electric scheme, satisfactory financial arrangements having been made.

Stouffville, Ont.—Board of Trade officials of this village are keen to launch a campaign to carry the Hydro Radial by-law, which is to be submitted on October 19. They have assurances from the Provincial Hydro-Electric Commission that Stouffville and the other midland towns will be the first in the Province to have a combined radial and power system if the proposed by-laws carry without a hitch.

Municipal

North Bay, Ont.—The council contemplate installing an incinerator.

Vancouver, B.C.—The Council has decided now to spend $15,000 on the water tower as was originally intended.

Toronto, Ont.—The Board of Control will spend $70,000 on paving material. Tenders will be called.

Winnipeg, Man.—Mechanical filters will be installed in a new public bath which the city is building.

Athabasca, Alta.—The town will build a reservoir and install a filtration plant. C. L. Huff is town engineer.

Point Grey, B.C.—The Council has ordered a combination chemical and pump wagon from the La France Co., at a cost of $12,200.

Toronto, Ont.—The Board of Control has voted $20,000, the city's share of the expenditure on the York Highways this year. The total amount spent was $60,000. George S. Henry, M.P.P., appeared before the board and asked to have the money provided.

Joliette, Que.—Tenders for "Hydraulic Plant" are being received. Plans, specifications and blanks for tenders may be obtained from Surveyer & Frigon, Civil Engineers, 56 Beaver Hall Hill, Montreal, after paying $5.00 for each set; this sum to be refunded upon return of plans and specifications.

Ottawa, Ont.—Unless some compromise is effected between Dr. McCullough, Chief Provincial M. H. O., and Mayor McVeity, the plans and specifications of the proposed new mechanical filtration system for Ottawa will not be passed upon by the Provincial Board of Health until its next general meeting. The cost of the new system is estimated at $2,000,000.

New Toronto, Ont.—Work in connection with the new waterworks scheme is now progressing speedily. The foundation of the new pumping station has been laid and the large well at the foot of Sixth street is in course of construction. The laying of the 18-inch steel intake pipe is also well in hand and will be completed in seven or eight weeks according to the contractor, J. F. Curley.

Canora, Sask.—At a meeting of the town council on August 26, the following tenders were recommended for acceptance:—Laying a force main, Flanagan & Murphy at $10,011; Pump house, Flanagan & Murphy at $5,345; Steel water tower, Dominion Bridge Co., $5,744; Cast iron pipe and specials, Can. Iron Corporation $17,887; Valves and hydrants, Jenkins Bros., $1,049; Chipman & Power, Winnipeg and Toronto are the engineers.

General Industrial

Windsor, Ont.—The J. T. Wing Co. are building a factory here. L. Weis, of Detroit, Mich., is the contractor.

Toronto, Ont.—The Ontario Government are operating successfully a red roofing tile plant at Mimico, Ont.

Ottawa, Ont.—It has been stated that the Government will give as far as possible additional orders for steel rails required in its railroad construction, that the work in steel mills may be kept up as long as possible.

Rigaud, Que.—An explosion in the powder works of Curtis & Harvey occurred recently. The cause of the explosion, which destroyed one of the

firm's buildings, and set fire to six houses, is unknown.

Windsor, Ont.—A $20,000 addition to the factory of the Remington Arms Co. is being made by Wells & Gray, of Toronto, architects and general contractors. The addition is to be one storey high, of steel, reinforced concrete and brick construction.

Ingersoll, Ont.—That Ingersoll is to have a new industry, a broom factory, which will be established by Thomas & Robertson, of St. Thomas, was the announcement made recently. Operations will likely be commenced about September 15.

Caledonia, Ont.—The Ebsary Fireproofing Co., Toronto, is in the market for mill equipment, including tracking kiln cars and turn tables, in connection with the mill for the manufacture of gypsum blocks now in course of construction here. F. S. Bridges is the manager.

Toronto, Ont.—Tenders will be received up till September 15 for excavation, laying and jointing of 42-inch and 36-inch cast iron water pipes. valves, and special castings. Plans and specifications may be obtained from the office of the Water Main Extension Service, Department of Works, City Hall.

St. John's, Nfld.—A brisk demand for the product of the paper and pulp mills in the interior of Newfoundland has resulted from the war. Steamers are rapidly arriving to take on cargoes for England. It is expected that the mills will be obliged to supplement their present equipment, and it is anticipated that new pulp and paper concerns will shortly be in operation. The demand is chiefly due to the increased needs of the newspapers in London and other British cities.

Ottawa, Ont.—The plant of the Canada Cement Works at Hull has closed down entirely, throwing over two hundred out of work. The closure is due principally to the loss sustained by the company during the latter end of July by the fire which destroyed two entire buildings, together with all the machinery. Mr. O'Neil, superintendent for the company, stated that the plant would not likely reopen before the beginning of next year.

Arnprior, Ont. — Manager Griffith of the Arnprior Felt Co., has returned from Philadelphia, in which city he purchased the machinery to be installed in the company's new factory now in course of erection in Arnprior. The machinery is ready for shipment and Mr. Griffith states that there will be no trouble in getting the factory under way within the time set down in the contract, Oct. 1st to 15th. The company is greatly inconvenienced by the war, and it is prevented from filling orders because of the impossibility of securing raw material, principally wool.

Building Notes

Winnipeg, Man.—Gordon Ironsides & Fares Co. have awarded the contract for their new building at Montreal to G. Gray & Co. of that city.

Victoria, B.C.—Proposed new large building constructions include a $450,000 hospital for which L. P. Rixford is the architect, and a $300,000 bridge for which the City Engineer is the architect.

New Westminster, B.C.—Garden & Mercer, architects of this city, have prepared plans for the proposed Court House, which is to cost $60,000. Tenders are called for September 15 for the general contract.

Toronto, Ont—A building permit was granted last Thursday to the Board of Education for a new school at East Davisville, to cost $43,600. The school will be two storeys high and of brick construction.

Toronto, Ont.—A building permit was issued to the Excelsior Life Co. by City Architect Pearse last Tuesday. The building will be eleven storeys high, will be constructed of steel, brick and terra cotta, and will cost $250,000. Peter Lyall & Sons' Construction are the contractors.

Railways—Bridges

New Glasgow, N.S.—A contract has just been awarded to the Eastern Steel Co., Ltd., of this town for the construction of 13 bridges in the Province of Nova Scotia.

Victoria, B.C.—It is announced that there will be no cessation of work on the P.G.E. railway construction, and that every effort will be made to push forward completion.

Toronto, Ont.—The committee of the Toronto Northeastern Hydro-Electric Railway met on August 19 to complete organization. The committee has finally decided to hold the voting on the agreement on Monday, Oct. 19, instead of Sept. 21.

Beamsville, Ont.—Surveyors are working on the proposed line from Queenston to Beamsville of the hydro-electric railway. The start of the survey was made at Queenston and the whole course is covered to Beamsville. This is just a preliminary survey.

London, Ont.—On account of the war all work will be stopped on the electrification of the London and Port Stanley Railway. The laying of steel rails had been completed, and the work of ballasting had just commenced when this decision was reached by the representatives of the Construction Company and the City.

Sudbury, Ont.—The contract for the construction of the permanent bridges voted upon recently by the ratepayers, namely Minto, Larch, Station and Durham streets, was let to D. L. Brown by the Council Monday night. The contract price is $23,100, for which Mr. Brown is to accept the town's debentures amounting to $25,000.

C. N. R. Ottawa Line.—A week ago, the passenger train service on the C.N.R. line between Toronto and Ottawa was opened. The line has practically been completed for some time, but is only now being used for traffic. The event will become memorable because of its taking place on the day the Parliament at Ottawa met to provide for the part Canada will take in the greatest war of history.

Saskatoon, Sask.—Plans for traffic bridges are in course of preparation, and later estimates of cost will be prepared. Work is being done on three plans for three different proposed bridges—at avenue A, at the present traffic bridge, and at 4th avenue. When they are completed, the commissioners will report to the council, but this will not be for some time, as much work yet remains to be done on the plans and estimates, and there is little likelihood of the work being proceeded with in the near future.

St. Catharines, Ont.—A by-law to construct a high level bridge across the old canal from St. Paul Street to Western Hill, near the Grand Trunk Station, was carried by the ratepayers by a majority of 313 on August 19. The bridge will be a steel structure, and, with approaches, will cost $220,000, of which the Grand Trunk Railway will contribute $20,000 and the Dominion Government $50,000, on condition that the city assume control of the present swing bridge across the canal at that point.

St. Catharines, Ont.—There is now a strong likelihood that the proposed St. Paul Street high level bridge to the Western Hill will be constructed much earlier than was expected when the by-law was carried by the ratepayers two weeks ago. The Works Department has already received word from various contracting firms offering to tender on the work and accept city bonds in payment. This would obviate the question of raising funds to finance the work and the fact that the bonds would act as a loan

against the work is another attractive feature.

Ottawa, Ont.—The Government have practically concluded an arrangement with the representatives of the Grand Trunk Pacific and the C. N. R. by which advances will be made the two companies sufficient to let them proceed with the completion of their transcontinental lines until the bonds for that purpose, guaranteed by the Dominion Parliament, can be financed. The Canadian Northern will do its financing through the Canadian Bank of Commerce, depositing a portion of the bonds with the Government, or rather with a bank or trust company acting for the Government.

Vancouver, B.C.—"Despite the chaotic conditions of the money markets, due to the war situation, we intend to finish up the transcontinental line as quickly as possible," announced Sir Donald Mann, C.N.R. vice-president. Sir Donald has gone to Victoria to confer with Premier McBride. He says that the company has 3,000 men employed in British Columbia, and will keep them at work until rail-laying is finished. Grading, he believes, will be finished by the end of next month. Steel has been delivered or is en route for all sections of the main line west of Yellowhead Pass, and much of the track work has been completed in the sections between Port Arthur and Toronto, which is to be in operation by September 15.

Wood-Working

Stratford, Ont.—The Stratford Chair Co. proposes to double its present plant.

Fort Frances, Ont.—It is reported that a large box factory will be built here.

Cochrane, Ont.—It is reported that Sir Adam Beck will build a box factory here. Power will be obtained from the Abitibi River.

Halifax, N.S.—Between $10,000 and $12,000 damage was done on August 27, when fire completely destroyed the woodworking mill of Davison, Parker & Co., Ltd., on Kempt Road.

Goderich, Ont.—A by-law will be voted on by the ratepayers to authorize a loan of $25,000 to the Goderich Furniture Co. The factory will be extended. J. E. Baechler is manager.

St. Thomas, Ont.—The stave mill, owned by the Sutherland Innis Co., a large wooden building was totally destroyed by fire on Sept. 2, and only part of the machinery was saved. The mill has been shut down for some time past, and the building was on the market for sale. The loss will be several thousand dollars, and is covered by insurance.

Vancouver, B.C.—The Sunset sash and door factory, owned by Arbuthnot brothers, formerly of Winnipeg, was destroyed by fire on Aug. 27. The loss is estimated at about $10,000.

Contracts Awarded

Sussex, N.B.—The sub-contract for the steel work erection at the agricultural college has been secured by the Phoenix Foundry, of St. John, N.B .

Toronto, Ont.—The contract for the construction of an addition to the high level pumping station was let by the Board of Control last Thursday to Page & Co. The work will cost $36,000, and will be commenced at an early date.

Edmonds, B.C.—The town has awarded to the Robertson-Godson Co., Vancouver, B.C., a contract for the supply of 10,000 feet of 4-inch main, the pipe supplied being manufactured by the Page-Hersey Co.

The Siemens Co. of Canada, Ltd., Montreal, P.Q., has been awarded the contract by the Dominion Government for the supply of submarine cables—23 knots of single conductor submarine telegraph cable (107 lbs. copper and 150 lbs. gutta-percha per knot), with sheathing of 12 No. 8 s.w.g. iron wires, to be delivered at Halifax, N.S.; and 14 knots of the same to be delivered at Vancouver, B.C.

Toronto, Ont.—The following contracts have been awarded in connection with the erection of the Upper Canada College buildings at Norval. Masonry, H. N. Dancy & Son, Mail Bldg., Toronto; steel, Hamilton Bridge Co., Hamilton, Ont.; steel sash, H. Hope & Son, 45 King street west, Toronto; carpentry, Oshawa Interior Fittings Co., 131 Deleware Ave., Toronto; plumbing, heating and ventilating, W. J. McGuire, Ltd., King St. W., Toronto; painting, W. M. Weeks, 37 Wilton Ave.; roofing and sheet metal, A. Matthews, Ltd., 256 Adelaide St. W., Toronto.

War Grist

McGill Graduates and the War Situation—The following letter has been sent to every McGill graduate:—At a time like the present, when the destiny of the Empire is at stake, McGill University and its graduates should come forward and do everything in their power to help the common cause. The individual probably does not fully realize the place the graduates as a whole have in Canadian affairs. Over 5,000 educated men, holding important positions all over the Dominion and elsewhere, are a tremendous power and influence, particularly if their efforts are concentrated on certain fixed objects. It was felt by the executive of the Graduates' Society and by the committee in charge of the reunion, which it had been proposed to hold in the fall of 1915, that in the present Empire crisis something should be done; and it was decided to write a letter to every graduate asking him to use all his influence towards patriotic ends. In order to make our influence felt in a definite way it was thought that a fund should be started, to which every graduate of the University would contribute. The contribution of each individual would be for the nominal amount of one dollar, which would represent his patriotic vote and the signification of his intention to do everything possible to assist Canada in the responsibility and duty created by the war. The vote of the McGill graduates will be deposited in cash form to the credit of the Canadian National Patriotic Fund. You are, therefore, invited to fill in and return the accompanying cheque form, which will be cashed at par, or to enclose one dollar in some other form. An immediate response is necessary if this action is to have all the effect that is hoped for from it. For the executive, John L. Todd, president; William Stewart, secretary. Remittances should be addressed to Geo. C. McDonald, 179 St. James Street, Montreal.

Personal

J. H. Plummer, president of the Dominion Steel Corporation, has gone to Sydney for about a month's stay.

J. A. Ruddick, chief engineer of the Dominion Coal Co., Sydney, N.S., has resigned his position to accept a similar one.

J. H. Clark, a member of the staff of R. E. Speakman, city engineer, has been appointed purchasing agent for Brandon, Man.

Sir Stephen Wilson Furness, widely known in the British shipping world, died on September 6. He was born in 1872.

D. H. Martin, division engineer of the Pittsburgh & Shawmut Railroad, has been made chief engineer of the new Welland ship canal, with office at Allanburg, Ont.

R. L. Dobbin has been appointed water-works superintendent for the Peterborough Utilities Commission,

"WILLIAMS" MACHINERY LIST

For Prompt Information Refer to "Machine Tool Dept."

NEW PIPE MACHINES.
No. 4, 2½ to 8" Williams.
No. 1½, 1 to 3" Williams.

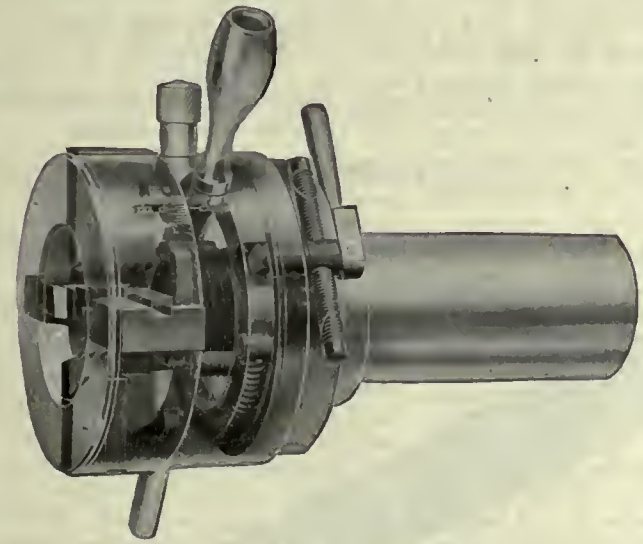
Don't forget we carry a large stock of genuine American Steel-Split Pulleys

Sizes 3" to 60" dia.

MISCELLANEOUS MACHINE TOOLS.
New 48" Boring Mill widened to 60" Stirk.
2-Spindle Moline Cylinder Boring Machine —almost new.
New 6x Diamond Disc Grinder.
Refitted 2¼ x 24 Stevens J. & J. Pattern Turret Lathe.
Refitted Stevens Universal Tool and Cutter Grinder.
Refitted No. 14 Besley Disc Grinder.
New No. 18 Gardner Patternmakers' Disc Grinder.
Refitted Walker Universal Grinder (outfit J).
New No. 2½ Bath Universal Grinder (equipment C).
Refitted No. 1 LeBlond Universal Tool and Cutter Grinder.
Refitted 8" Bertram Slotter.
Refitted 10" Peacock Slotter.
Refitted 36" Gould & Eberhardt Spur and Bevel Gear Cutter.
New No. 2 Schuchardt & Schutte Gear Hobbing Machine.
New No. 1 Catlin Keyseating Machine.
Refitted 2½ Morton Keyseating Machine.

IF IT'S MACHINERY WRITE "WILLIAMS"

The A. R. Williams Machinery Co., Ltd., 64-66 Front St. W., Toronto



Phantom View Style "D" Die Head

Twenty-five Die Heads Thrown Out of One Factory and Replaced With Geometric Die Heads!

Does not this prove that **THE GEOMETRIC** is King?

Perfected in all its working parts, you will find the Geometric in good live shops, on Hand and Automatic Screw Machines.

Every Screw Machine Manufacturer recommends and furnishes the Geometric as a part of the tool equipment.

For cutting any diameter, length or pitch of thread.

When the required length has been threaded, the dies open automatically, and are withdrawn without touching the thread.

No Waste of Time or Material. **Send for Our Catalogue.**

The Geometric Tool Company, New Haven, Conn.

Canadian Agents:
Williams & Wilson, Montreal. The A. R. Williams Machinery Co., Toronto and Winnipeg

Peterborough, Ont. Mr. Dobbin was formerly resident engineer on the Moose Jaw water supply.

Joseph A. Day, manager of the Cleveland Pneumatic Tool Co., of Canada, Ltd., Toronto, has gone to Chicago, Ill., to attend the American Foundrymen's convention which is being held there. The Cleveland Pneumatic Tool Co., Cleveland, O., have an exhibit there.

G. W. Robb has resigned the position of superintendent of motive power of the G. T. R., and is succeeded by Joseph Billingham. Mr. Billingham was at one time connected with the London & North Western Railway, England. He will make his headquarters at Transcona, Man.

M. A. Lyons, a graduate of 1910 from the Massachusetts Institute of Technology, has been appointed Chief Engineer to the Highway Commission of Manitoba. Mr. Lyons is to have general supervision of survey, design and construction of roads and bridges under the recent "Good Roads Act" in that province. His headquarters will be in the Parliament Building, Winnipeg.

P. G. Donald has recently arrived in Canada from England on behalf of a syndicate of British steel merchants. His mission is to interview the steel interests of Canada to see whether Canadian manufacturers can stop the gap caused in the building trades by the cessation of imports from Germany and other continental factories. These imports include German wire nails, iron tubes for gas and water, and steam pipes.

M. C. J. Bellingham, W. A. Newton and W. D. Cook have formed a partnership under the name of Bellingham, Newton & Cook, engineers and architects, with offices at 213-14 Confederation Life Building, Toronto. They were until recently on the staff of D. J. Albertson, of Kalamazoo, Mich., engineering specialist on pulp and paper mills. Mr. Newton has been for some time in charge of Mr. Albertson's Toronto office, which was closed recently.

G. Gordon Gale for many years general superintendent of the Hull Electric Co., has recently been appointed general manager. Mr. Gale is a graduate of McGill University and has had valuable experience both in operation and management. Prior to 1907 he was assistant engineer of the electric plant of the Canadian Rubber Co. In that year he become associated with the Hull Electric Co. and has filled successfully the positions of superintendent of power, acting superintendent, and, for the last five years, general superintendent.

Trade Gossip

The Harland Engineering Co., power engineers and contractors, have removed from 26 Victoria Square to larger offices at 102 St. Antoine Street, Montreal.

The Canadian Vickers, Ltd., Montreal, recently purchased a 600 ampere arc welding set from J. D. Lachapelle, Canadian sales manager of the C. & C. Electric & Mfg. Co.

Errata.—The underline for cut which appeared on page 197 of our August 27 issue should have read "NATCO," No. 30 Multiple Spindle Drill instead of National Acme, No. 30, etc.

The A. R. Williams Machinery Co., Ltd., Toronto, have sold a number of motor-driven tools to the Glass Garden Builders, Ltd., Toronto. The tools include a lathe, planer, cut-off saw, pipe machine, high-speed drill press, etc.

Verdon Cutts & Co., 87 Fargate street, Sheffield, England, have made an arrangement with the Hare Engineering Co., Toronto, to build the Fulton Water Cooled Mechanical Stokers in England for export to Foreign Countries.

The Hare Engineering Co., Toronto, have appointed as their Manitoba and Saskatchewan representatives, Refrigeration and Engineering Co., 700 Portage Avenue, Winnipeg, Man., to whom all inquiries arising in Manitoba and Saskatchewan should be addressed.

The Hare Engineering Co., Ltd., Toronto, have secured the Canadian Agency for the Bulkley Barometric Condenser, from the M. W. Kellogg Co., New York, who have arranged to push this condenser by means of its various local agencies.

Errata.—In the article on the A. B. Ormsby Co.'s plant in Aug. 27 issue of Canadian Machinery, mention should have been made of the complete equipment of ball bearings which were supplied by the Chapman Double Ball Bearing Co., of Canada, Ltd., Toronto.

The Canada Metal Co., Toronto, are showing, at their booth at the Toronto Exhibition, an extensive line of babbitt metal, solder, lead pipe and ingot metals. A new line this year is the Plumbers' Supply Department. The booth occupied by this company is the same as last year, near the south entrance.

The Hare Engineering Co., Toronto, manufacturers of mechanical stokers, report a considerable increase of business during the month of August. They secured a number of contracts, among which are the Seminaire de Rimouski, Rimouski, Que.; College de L'Assomption, L'Assomptionville, Que.; Canadian Pacific Railway, Glen Yards Shops, Montreal; Chipman-Bolton Knitting Co., Hamilton, Ont.; Fulton water cooled mechanical stokers will be installed in each case.

The Elliott Company, Pittsburg, Pa., has appointed William A. Day, to be Chicago district sales manger. Mr. Day was formerly sales manager of the Erie City Iron Works in the Chicago district, and is well known both as a salesman and as an engineer. The Elliott Company's Chicago office will be as heretofore, at 527 Monadnock Block.

The Elliott Company, Pittsburgh, Pa., has appointed George Gray, of Boston, Mass., Sales Manager for the New England district. Mr. Gray is well known in the New England territory, and was connected with the Elliott Company's interests several years ago. The office of the company will remain at 954 Oliver Building, Boston, as heretofore.

Iroquois Falls, Ont.—By the first of May next it is expected that the installation of the new pulp and paper equipment of the Abitibi Power & Pulp Co. will have been completed, and that the new plant at Iroquois Falls will be working to capacity. At the present time between 150 and 160 tons of pulp are being manufactured daily, the shipment of which is about equally divided to Canadian and American points. Within sixty days this output will be increased to 240 tons per day, as six new machines are to be installed immediately. The daily capacity of the mill next May will be from 200 to 240 tons of newsprint, from 240 to 260 tons of ground wood, and about 60 tons of sulphite.

Steel Conditions.—J. H. Plummer, president of the Dominion Steel Company, stated at Montreal that he was hopeful that conditions in the steel trade would improve before long and work a favorable influence in certain lines in Canada. He said that before the war broke out business had been improving slowly, and the corporation had been getting exceptionally good results at its various plants. Naturally business had been completely upset since then, and it would take a little time to form any definite opinion on the outlook. Mr. Plummer will spend the next few months at Sydney. It is reported from Philadelphia that Canadian steel plants have been selling some of their surplus supply of ferro-manganese to United States firms at very high figures, making $50 to $60 a ton on some of the transactions.

The Canadian Tungsten Lamp Co., of Hamilton, Ont., has felt the effects of the war in a beneficial manner. Many companies which secured most of their lamps from Germany have been forced to place their orders with the local con-

cern, and sufficient orders to keep the plant running at a fair rate have been received. W. H. Ginder, manager of the plant, stated that, while the company had been able to secure trade which otherwise would have been given to German firms, it was facing a difficulty in that all of the platinum used in the manufacture of the lamps comes from Russia, and it is difficult to secure an adequate supply. The company has sufficient platinum to last a few months, and Mr. Ginder is hopeful that in the meantime further shipments will be received. The company is endeavoring to keep all of its men employed, and denies that a cut has been made. Owing to the difficulty in securing raw materials, the lamps will cost more, and a new price list is being issued.

Toronto Board of Trade.—A representative meeting, presided over by President W. P. Gundy, of members of the board from almost every industry and class of business, was held in the Council Chamber of the Board of Trade on September 4, to discuss ways and means of fostering Canadian trade. It was felt that the present was a very opportune time for Canadian manufacturers to extend their markets and to manufacture new lines heretofore imported into Canada, and that the stimulation of Canadian manufactures in this way would necessitate full staffs, and consequently relieve unemployment to a large extent. Those present resolved themselves into a special committee for the study of the question, and unanimously appointed A. O. Hogg chairman. Messrs. A. O. Hogg, H. C. Boulter, C. D. Daniel, M. C. Ellis, E. Holt Gurney, Arthur Hewitt, Henry H. Mason, Miles Vokes and C. H. Willson were appointed an executive committee, with power to add to their numbers, to nominate sub-committees for the gathering of statistics and secure suggestions from all lines of industry as to the best method of attaining the object in view.

The New Process Gear Corporation, Syracuse, N.Y., reports that it is working overtime to keep up with a volume of business larger than any heretofore handled. Although the plant was doubled in capacity less than two years ago and was at that time claimed to be the largest in the world devoted exclusively to gear making, an additional building is now being erected, and the capacity of the case-hardening and heat-treating departments are again being doubled. Additional equipment already ordered for fall delivery includes:—10 Fellows gear shapers, 15 Gleason bevel gear generators, three Bullard vertical turret lathes, three Heald grinders, one Landis grinder, two National acme automatics and numerous special machines built to designs worked out by engineers of the company. The total production of the plant in spur, spiral and bevel metal gears and New Process noiseless gears and pinions will after January 1st, 1915, be in excess of one million per year. A large part of this output is already contracted for by customers who have for years been large users of the New Process product.

M. Beatty & Sons, Ltd., Welland, Ont., builders of dredges and excavating equipment, recently launched dipper dredge at their shipyards on the Welland canal. She has been built for The Randolph Macdonald Co., Toronto, and will be of the boom and A-frame type with a 3½ cubic yard dipper to work in thirty feet of water. The steel hull is 107 feet long with 36 foot beam. It is 9 feet 3 inches deep at the bow and 8 feet 3 inches at the stern. The boiler is of the Scotch marine type and is of ample size to furnish steam for the entire dredging plant when working under heavy load. Worthy of note are the bow anchors. Instead of wood, these are made of steel plating, 28 in. x 30 in. x 55 ft., with a circular reinforcement on the inside, forced into place and firmly riveted. All the sheaves and bearings as well as the anchor points are of open hearth steel castings. The builders expect to finish work on the dredge early this fall.

Catalogues

Accumulators.—Bulletin "Section A" issued by Canadian General Electric Co., Toronto, describes the Electric Storage Battery Co.'s chloride and tudor accumulators for electric railway service, central lighting and power stations, isolated lighting and power plants, interlocking switch and signal service, telephone, telegraph, fire alarm, laboratory and small motor work.

Overhead Runways made by the Herbert Morris Crane & Hoist Co., Toronto, are the subject of bulletin B.8. The Q. E. F. runway is made in capacities from a quarter of a ton to three tons, and its application is shown in this bulletin by means of views taken at the plant of the A. B. Ormsby Co., Toronto. The illustrations demonstrate the saving in time and labor secured by the use of overhead runways.

Grinding Face Mills is the title of an attractive catalogue, No. 35, recently issued by the Ingersoll Milling Machine Co., Rockford, Ill. A full description is given of the Ingersoll face mill grinder, in connection with which is a sectional view of the machine. In addition are included specifications covering 24, 30 and 36-in. face milling cutter grinders, while illustrations show the machine in operation. These are exceptionally good and the reading matter is set in clear type.

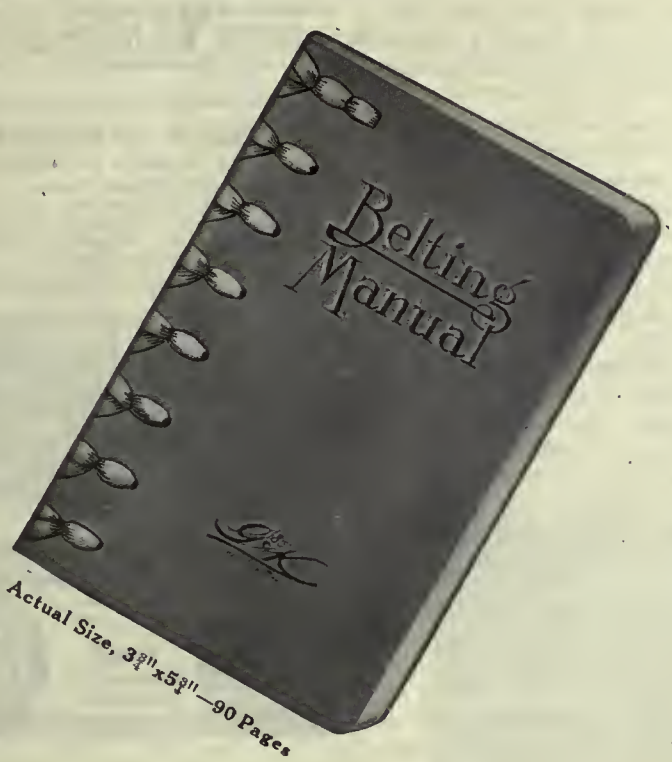
Strainers.—The Lagonda Mfg. Co., Springfield, Ohio, has just published a complete 20-page catalog descriptive of their multiple water strainers for power plant and pumping station intake lines. These strainers are of the multiple straining basket type, which can be easily and quickly cleaned without interruption to the flow of water. Other Lagonda products, such as boiler tube cleaners, automatic cut-off valves, reseating machines and tube cutters are also described and illustrated. The new catalog is entitled the Lagonda Multiple Strainer, edition R-2, and will be sent upon request.

The Lufkin Rule Co. of Canada, Ltd., Windsor, Ont., announce the issuing of their new catalog, No. 9, now ready for distribution. Its 110 pages are devoted exclusively to measuring tapes and rules, making it unquestionably a most complete catalogue of such goods. The various items throughout the book are well arranged, and most comprehensively presented. The embossed cover is of strikingly original design, executed in the Lufkin stock label and box colors, tan and maroon. In the catalogue, the special attention of the trade is invited to the fact that in addition to measuring tapes, steel rules, etc., the company now manufacture a complete line of folding boxwood and flexible spring joint wood rules, and carries a full stock on both, enabling them to make prompt shipments. All requests for copies of the new catalogue will receive prompt attention.

Book Reviews

The Log Book of the Power Plant is the title of a book published by the Yarnall-Waring Co., Philadelphia, Pa., and deals principally with the Lea Notch Liquid Recording Meter. This book might well be called a treatise on metering feed water for it contains much valuable information on the subject, although with special reference to the Lea apparatus. Among the principal contents of the book are the following subjects:—The value of a recording hot water meter; advantages of measuring boiler feed and condensate; the various methods of water measurement; the inherent advantages and applications of the Lea V-Notch Meter; authentic tests by well-known engineers, with data obtained. In addition to the above, several tables are included, giving capacities, dimensions and shipping weights of various types of Lea meters, accompanied by diagrams. The book contains 88 pages and numerous illustrations, diagrams and charts covering the various

THE BELTING MANUAL



Actual Size, 3¾"x5¾"—90 Pages

Yours for the Asking

To obtain the highest efficiency in power transmission, is the problem which confronts every manufacturer. For years leather belting has demonstrated its ability to stand more abuse and come out "alive" than any other means of power transmission. It is an undisputed fact that if leather belting is given a tithe of the attention which of necessity must be given to other forms of transmission, it will demonstrate beyond question its greater efficiency and economy.

To promote this efficiency and economy is the fundamental object of

The "Belting Manual"

with its 90 pages of practical belting information.

It tells how to install belting, how to care for belting, how to repair laps, how to make belts endless, how to apply dressings, how to lace belts, how to clean belts, how to remedy some of the belt troubles, how to find width and length of belts.

The various mechanical rules are unusually complete, and compiled for use in solving the daily problems of power plant practice. In short, the "Belting Manual" is an authentic text-book on the transmission of power—it is a veritable fund of information for every belting user.

FOR SALE

Owing to new arrangements for the manufacture of our products, the following used equipment is for sale. We guarantee everything in first-class condition. Inspection invited.

1 Becker-Brainard Milling Machine with Rotary Table and Special Attachment.
1 Reed Lathe with Taper attachment.
1 Springfield Turret Lathe.
1 Diamond Speed Lathe.
1 Fox Drill, two-spindle.
1 Hendey-Norton with taper attachment.
1 Cincinnati Vertical Milling Machine.
1 Universal Cutter and Tool Grinder.
1 Reed Lathe.
1 20" High Speed S.H. Drill with round table, Cone drive and Tapping attachment.
1 22" Barnes Drill with power feed.
1 Small Grinder.
1 18" Back-Geared Shaper, Queen City Machine Tool Co.
1 Metal Band Saw, No. 2.
1 Champion Blower and Forge.
1 Eclipse Fuel Engineering Co. Oven Gas Furnace.
1 Eclipse Fuel Engineering Co. Gas Oil Tempering.
1 Gas Heated Caldron Sheet Steel Enclosure.
1 Belt-Driven Rotary Pressure Blower
1 Grenard No. 3 Bench Arbor Press.

types of meters together with many installations, etc. It is printed in bold, clear type, and indexed.

Steel Working and Tool Dressing by Warren S. Casterlin, 207 pages, indexed, cloth bound. Published by M. T. Richardson Co., 71-73 Murray St., New York, price post paid, $2.00. This is a manual of practical information for blacksmiths, toolsmiths and other workers in steel and iron. The writer of the book is a mechanic of over fifty years practical experience who has been successful in all parts of America. Too many of the so-called practical books to-day have been written by men whose active experience was gained within the walls of colleges and technical schools. The language of these men is often uninteresting to the bulk of mechanics who are not attracted by knowledge that has no direct bearing upon their work. The writer of this book presents the information that schools cannot get, and the steps that have carried many mechanics to the top of the ladder. The work begins with a timely word to apprentices and those who have to deal with them. Following this is a brief history of the development of tool steel and the various steps that have led to its present high standard of quality and efficiency; likewise the explantations of the peculiar behaviour of different steels under the necessary treatment accorded them by the smith are explained as by a fellow worker. Much space is devoted to the care and proper use of tools and equipments which, if carefully perused by the young mechanic, will enable him to accomplish the best results with the least expense of physical effort and financial outlay. The great body of the book is taken up with labor-saving means of doing every day jobs as well as a large number of kinks and tricks of the trade for those troublesome pieces of work whose difficulties seem to have no logical explanation. The subject is divided into over 200 topics rather than into chapters each of which is plainly indexed for easy reference. The book is well bound, is printed on strong paper and is evidently intended for use in the shop rather than to adorn the book shelf at home. It will serve to meet the need of a text book for these undertaking the blacksmith trade at the beginning, as well as those older heads who are seeking to improve themselves and who have not had the benefit of the author's long experience and extensive travel.

The Plant of the Canadian Buffalo Forge Co., Berlin, Ont.

By J. H. Eastham

On account of lack of room to extend their Montreal factory, and with a view to centralizing their trade now established from coast to coast of the Dominion, the Canadian Buffalo Forge Co., after inspection of various possible sites decided to locate at Berlin, Ont. That this progressive concern is alive to Canada's domestic needs and export trade is easily apparent from the description here given of the plant layout and its equipment.

AS in the case of most industries which have changed their location or have recently established themselves in Canada, the Canadian Buffalo Forge Co. have taken the wise precaution of acquiring as the initial step, not only suitably situated land for transportation purposes, but sufficient of it for a well-ahead future development. Eight acres of land to the sonth of the City of Berlin were purchased and the erection of a number of manufacturing buildings was started in September of last year.

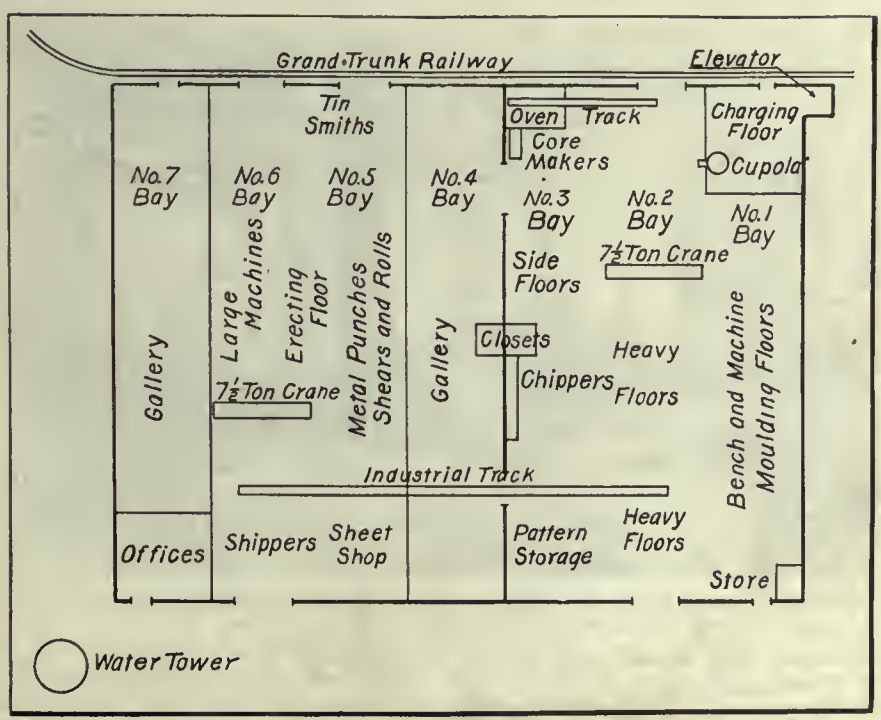
The plant as at present constituted has been in operation since May 1 of this year, and comprises a foundry and blacksmith shop in three bays, sheet iron fan and blower department in two bays; erecting shop, one bay; machine shop, one bay; a total of seven bays covering 210 ft. by 160 ft., every bay being 160 ft. by 30 ft., placed east and west in the order named. The company are fortunate in possessing unusually good receiving and shipping facilities, a siding from the Grand Trunk Railway serving each bay independently as shown in the ground plan at Fig. I.

Foundry.

The foundry, laid out in three bays, of 160 ft. by 30 ft. each, is particularly well equipped for handling heavy jobbing castings in addition to the company's regular lines. Raw material is received at the north-east corner, a Roelofson elecetric elevator at this point serving a reinforced concrete charging floor 33 ft. by 30 ft. in area, tested to 500 lbs. per square foot. Undue handling of coke and iron is thus to a considerable extent avoided.

For present needs, one No. 3½ **Whiting** cupola, 52 ins. diameter inside shell, and lined to 40 inch., has been installed, ample room being left for the erection of another of equal or larger proportions should increasing business require it. A Buffalo Forge Co. fan, 46 ins. diameter driven by a direct coupled **Crocker-Wheeler** motor of 30 horsepower at 1,472 revolutions per minute, gives a blast pressure of 13 ounces, and an average melt of six tons per hour.

CANADIAN BUFFALO FORGE PLANT EXTERIOR, LOOKING SOUTH.



PLANT LAYOUT, CANADIAN BUFFALO FORGE CO.

To facilitate the cheap output of the smaller parts on their standard hearths, such as drilling machinery, etc., which runs into many thousands annually, the company have installed a No. 20 **Arcade Modern** molding machine. This machine is placed in the eastern bay of the foundry, as near to the cupola as convenient, the remainder of the bay (for descriptive purposes here termed No. 1), being occupied by bench and side floor moulders.

The center or No. 2 bay, spanned by a 7½ ton **Niles** crane, operated from cab or ground, is used for the production of heavier castings. No. 3 bay is utilized by light floor moulders, blacksmiths and coremakers, for pattern storage, and chippers. Two 5 ft. by 2 ft. rumblers, wood cased to deaden sound are located in this bay for chippers' use.

The blacksmiths are served by double hearths of cast iron type, blown by the company's **200** silent-electrically driven blowers, of **2E** type, a small monorail

crane being placed over the brick lined furnace required for the heavier forgings.

In the north-west corner of this bay, and immediately over the boiler room,

ERECTING BAY, GALLERY AND MACHINE SHOP, LOOKING SOUTH.

one coke fired core oven, 12 ft. long by 10 ft. wide by 8 ft. deep, has been erected, provision being made for the use of the waste heat from the boiler stack during the winter months for drying purposes.

In addition to the admirable sprinkler system installed throughout the plant, the works manager, S. Halfyard, has devised an exeellent spray system for the foundry roof, a series of nozzles operated from the floor drenching the area for several yards round the eupolas at the beginning and elose of each heat. The risk of fire from sparks is thus entirely eliminated.

Fan Erecting Department.

The sheet steel fan and blower erecting shop, parallel with and adjoining the foundry, is roomy and well equipped, two bays, covering collectively 160 ft. by 60 ft., being equipped with one Buffalo Forge Co. punch and shear with armour plate body; one puneh of similar type, one brake, one guillotine shear, two sets of rolls, and one large hand brake.

In this department also, for patternmakers and general carpenter's use, one **Cram** combination woodworker of the company's own make, and several rip and straight-cut circular saws have been placed, their central position rendering them easily accessible to shippers for crating purposes.

The north end of the two bays, Nos. 4 and 5, is oecupied by tinsmiths. An air compressor with 8 ins. eylinder is placed on this floor temporarily, whilst the gallery covering No. 4 bay as shown on ground plan, is at present with the exception of patternmakers tools and benches, used mainly for storage.

Erecting Shop.

No. 6 bay devoted almost exclusively to erecting and shipping purposes, is 160 ft. long by 30 ft. wide, and is spanned by one 7½ ton **Niles** crane of same type as that in No. 2 bay of the foundry. It has excellent facilities for shipping and receiving goods by rail at its north end, or by teams at its southern entranee.

Machine Shop.

Bay No. 7, 160 ft. long by 30 ft. wide, is equipped with maehinery as follows:

One Kearney & Treeker, Milwaukee miller.

One Mitts & Merrill, keyseater.

One McGregor Gourlay miller.

One Jones & Lamson geared head lathe.

One American Tool Works geared head lathe.

One Hoefer Mfg. Co., form head drill

One Stirk, Halifax, England, 36 ins. x 10 ft. planer.

One London Machine Tool Co., lathe.

One R. McDougall Co., Galt, lathe.

One Reed-Prentiee lathe.

One Gisholt Maehine Co. lathe.

One Bertram, Dundas, lathe.

One Hoefer Mfg. Co., drill.

Two shapers; one boring machine; three radial arm drills, one being of 14 ft. radius; one universal miller; one maebine haek-saw; one centering maehine; one small gear hobber; two pipe threading maehines; one large gear hobber; one pipe eutter; one 12 ft., 6 in. toggle press; one 10 ft. squaring shear (¼ in. capaeity); one 10 ft. squaring shear of No. 10 gauge capaeity.

Hans Renold chain is used on all main drives. The line shafting, 3 11-16 ins. diameter running in Chapman ball bearings, is driven by Canadian Croeker-Wheeler motors operated by eurrent supplied by the Ontario Hydro-Electric Commission. The gallery in this bay is utilized for the assembly and painting of the smaller and medium sized blacksmith forges and drilling maehines manufactured and eatalogued by the company. The main switchboard, heating and ventilating equipment, the latter also a product of the firm, is also loeated in this seetion.

The south-west corner of this bay is oecupied by the general offiees, whieh eonsist of two stories. On the ground floor are located the time office, general stores and foremen's lavatory.

Sheet Metal Shop Equipment.

One Lennox throatless shear, supplied by the Canadian Lennox Throatless Shear Co., Toronto.

One 10 ft. drop brake supplied by the Brown Boggs Co., Hamilton, Ont.

One set of 8 ft. heavy power rolls, supplied by the Brown Boggs Co.

One set of 4-ft. light power rolls supplied by the Brown Boggs Co.

One 10 ft. splitting shear, supplied by the Brown-Boggs Co.

One 10 ft. power truss brake, supplied

NORTH EAST CORNER OF FOUNDRY SHOWING CUPOLA, CHARGING FLOOR AND PORTION OF CENTRE BAY

by the Double Truss & Cornice Brake Co., Buffalo.

Two 8 ft. hand truss brakes, makers as above.

One flanging machine supplied by the Buffalo Forge Co., Buffalo, N.Y.

One power punch, one hand punch and one combination punch and shear, all supplied by the Buffalo Forge Co., N.Y.

The interior of the various buildings is faced with white glazed brick which, together with the ample natural lighting provision tend to make operating conditions in every respect ideal. Artificial lighting has also been given careful consideration, there being installed in each department and in such manner as to shed their full lighting effect without interfering with present or future overhead crane arrangements or extensions, a full complement of 250 Watt lamps. Ellis & Howard, Berlin, Ont., are the electrical contractors.

The roofs and crane girders are supported on Georgia pine columns set in cast iron bases on concrete foundations.

Two shower baths and four hand basins are provided in each department for the use of the employees.

STEAM BOILER MAINTENANCE AND INSPECTION.

WHAT follows is an abstract from a paper by H. A. Baumhart of the Hartford Boiler Inspection & Insurance Co., of Cleveland, O., read before the annual meeting of the Ohio Society of Mechanical, Electrical and Steam Engineers.—

Great progress has been made in steam boiler design and construction during the past twenty years. In fact, there are but few, if any, boiler manufacturers who would to-day construct a boiler for a given pressure without taking into consideration safe rules as adopted by provinces and municipalities or as recommended by good steam engineering practice.

Retiring Age for Boilers.

The subject of a proper retiring age for old steam boilers is one which comes frequently to light and is a most fruitful source of controversy. Of course there can be no question as to the propriety of condemning to forced retirement those boilers whose diseases of one sort or another have reached the chronic stage, and are no longer curable, but there is at once the basis for a deal of argument when an inspector approaches the owner of a boiler with the statement that it must be replaced because of old age, especially if it is known to have all the apparent qualifications, except youth, for many additional years of service.

In the past many curious properties have been attributed to old boilers; one of the most interesting was the notion that they could not explode violently. It was supposed that an old boiler would merely rupture, allowing the pressure to be relieved much as if the safety valve had opened. This idea was definitely disproved many years ago along with many other fallacies and much popular mystery concerning boiler explosions.

Service Deterioration.

We all know that steel used in boiler construction will deteriorate with use. It undergoes a slow loss in strength and ductility. The process is hastened by the presence of a moderate excess of phosphorus. Deterioration of this character cannot be determined by the usual method of inspection. It is, therefore, difficult to state definitely at what time in service the boiler should be abandoned. It places a great responsibility upon the inspector. He must consider, in addition to the general appearance of the boiler, the conditions under which it has operated, and he must also make allowance for defects in the material which are not visible.

Experience shows that boiler plate, subjected to the high temperature of the furnace, does deteriorate to the extent that after about 20 or 25 years' service, the boiler should (if we follow the motto "Safety First") be taken out of service. Because an inspector reports that he considers the boiler unsafe for further use, it does not imply that he can predict the day and the hour when it will explode; it does mean, however, that the factor of safety is too low, and to continue the boiler in service for any considerable length of time presents a hazard too dangerous to be undertaken.

Boiler Explosions.

No mysterious agency enters a boiler to cause an explosion. A steam boiler explodes or fails from one cause only, and that is the fact that the boiler or the part which fails could no longer resist the strain placed upon it. The applied pressure may be sufficient to rupture a sound boiler, or the boiler may have reached such a state of deterioration that the ordinary working pressure becomes an over-pressure. In the majority of serious explosions, the primary cause was due to the lap seam form of construction.

Many accidents are due to overheating of the shell plate or tubes. The overheating may result from various causes. The common cause is due to a deposit of scale, sediment, oil, or a combination of oil and scale on the internal surfaces. The presence of oil or grease, although in moderate amounts on the internal surface of a shell plate or tube, is a dangerous condition, and, unless removed promptly, will result in a damaged or possibly an exploded boiler. Great care should be exercised to prevent oil entering a boiler.

By referring to the records of the Hartford Steam Boiler Inspection and Insurance Co., I find the following data given in Table I on boiler explosions for the United States during 1911-13.

TABLE I.—DATA ON BOILER EXPLOSIONS IN UNITED STATES, 1911-13.

Year.	Boiler explosions.	Persons Killed.	Persons Injured.	Persons Total.
1911	499	222	416	638
1912	537	278	392	670
1913	499	180	369	549

The annual property damage is estimated at $500,000. The above records include boiler accidents of every description, some of which were of minor importance. This record is not an alarming condition and, in fact, we are very much encouraged because of the great interest now taken by engineers everywhere insisting upon proper construction and inspection of steam boilers. In many localities compulsory inspection is required by law. The situation therefore as regards safety is gradually improving.

We have not reached the stage of no boiler accidents. Such a condition will never exist. There will be boiler explosions as long as steam boilers are used as a unit of power. We have not yet reached the stage of perfection in the manufacture of material, neither have we reached perfection in the art of boiler design. We learn as much from the result of failure as from the result of success. Further experiences in the operation of steam boilers may teach us that some radical change in design or character of the material is required to make boilers that will not explode under constantly increasing pressure and temperature.

Care and Management.

Another condition which must be considered in connection with the safe operation of steam boilers is their care and management. It frequently happens that a boiler explosion, or some other calamity resulting in loss of life, occurs at places where it is least expected. This proves that, in spite of the advanced precautions that science has provided, reliance must still be placed in human intelligence and faithfulness to a large degree and that sometimes these fail.

It is recommended that boiler owners and users provide every possible method of safeguarding human life and property by purchasing only such boilers as have been thoroughly inspected during course of construction and by seeing that they are also inspected during the life of the boilers. It also devolves upon the owner or user of a boiler to select only such persons as are fitted to care for them.

The Goldie & McCulloch Co., Ltd., Galt, Ont., have been awarded a large contract for safes by the Royal Trust Co., of Montreal. The order is an exceptionally large one and will keep the safe department busy for some considerable time.

The Evolution of the Railroad Shop on This Continent

By A. I. Totten *

The railway shop of the present day is constructed to a radically different design from that in vogue only a decade and a half ago. In the accompanying article which recently appeared in the General Electric Review, the writer deals with the changes that have taken place and shows how the old sources and means of power supply have been advantageously supplanted by electricity.

THIS continent has just passed through an era of steam railroad shop construction unparalleled in the history of railroads. The poorly lighted, antiquated buildings located at division points have been demolished, and in their places there have been erected structures which are representative of the best engineering practice, and which are designed to provide maximum economy in the performance of repairs on cars and locomotives. When we consider these modern shops it is difficult to realize that but a brief fifteen or sixteen years have passed since the first shop to be built along present lines was placed in operation.

The Earlier or Unit System.

In older days it was the custom to locate small shops at objective points on the system, where changes in locomotives on through trains were effected. These shops were designed not only to take care of the general overhauling of locomotives and cars but also to provide storage facilities for engines when not in service in the form of a rond-house and the necessary adjuncts consisting of turntable, coaling station, sand house, oil house, water tank, etc. This is what might be termed the "unit system," inasmuch as each division had the exclusive handling and repairing of all locomotives assigned to it. With the introduction of cranes and other labor-saving devices it was ascertained that, in order to reduce the unit cost of repairs, this expensive machinery which was provided must be worked at its full capacity. Therefore, the practice was instituted of placing large main shops at central points for the performance of the heavy general repairs on locomotives assigned to several divisions, and the light running repair work was done at small shops or in roundhouses located at terminals or division points.

The handling of the various parts of the older types of locomotives and cars did not entail the difficulties now encountered in the transference of material in and around the various buildings, which must of necessity be scattered to a considerable degree to allow for trackage space, and also to reduce the fire risk which might otherwise prevail. The weights of engines have steadily increased from 135,000 pounds in 1890 to 330,000 pounds, which represents the weight of the triplex locomotive recently constructed for the Erie Railroad. With the increase in size of the rolling stock, the various components comprising the complete units have become heavier and heavier, and parts which were formerly handled readily by manual labor must now be lifted and transferred to the point desired by hoists and cranes.

Introduction of D.C. Electricity.

The introduction of electricity in the shop was made initially for the purpose of producing artificial illumination which would supplant that furnished by oil, candles or gas. The development of the direct-current motor provided a means for driving shafting in the various buildings; and thus made it possible to discard the numerous boiler and engine installations that were distributed throughout the plant and to supplant them by a central power-house from which the current could be transmitted over wires to the motors in the different buildings. This did not materially affect the output of the shop, but it reduced the cost of power by decreasing the amount of fuel and labor required for its generation.

In view of the general satisfaction which resulted from the successful operation of the group-drive system just described, railroad engineers as well as electrical manufacturers perceived the advantages that would accrue by equipping the larger machines, having variable-speed characteristics, with individual motors. An individual equipment of this sort would provide means by which speed variation could be readily obtained by a controller and resistance, thereby conserving the operator's time through eliminating the necessity for shifting belts on cone pulleys, as had been required previously. This was accomplished by what is known as the multiple-voltage system, so called because several line voltages were provided by balancer sets installed in the power house and connected across the terminals of the generating apparatus. The application of the proper potential for the motor speed desired was obtained by a controller located at a convenient point for manipulation by the machine tool operator.

Inasmuch as the motor capacity varied in almost direct proportion to the voltage applied, it will be readily appreciated that this system was not wholly suited for machine tool operation where practically constant horse power should be maintained over the entire speed range. In fact, the difficulties experienced in the operation of the multiple-voltage system demonstrated the inapplicability of this method of speed control for machine tool operation. A further study of the subject resulted in the introduction of the adjustable field control motors, which admirably fulfilled the requirements of the service and are representative of standard up-to-date practice.

With the introduction of electricity for power purposes in railroad shops came the traveling crane, varying from five tons to one hundred and fifty tons in capacity. This replaced the hand jack, pneumatic hoist and manual labor. The work of lifting locomotives from their wheels and replacing them thereon was accomplished in seconds instead of hours, and the handling of heavy parts through the shops and yards was performed rapidly and with a minimum amount of labor and cost. The individual machine hoists were discarded as unnecessary; but strange to relate they are now being replaced, as it was ascertained that a considerable amount of the tool operator's time was lost while waiting for the traveling crane to handle material around the machine.

Alternating Current Motor Introduction.

We have up to this point mentioned direct current only for shop operation; but with the introduction of alternating-current motors on a cost and operating basis comparable with direct-current motors, as regards constant speed service, they naturally became quite a factor in railroad shop installations. It is difficult to compare the relative merits of alternating and direct current as applied to railroad shop operation. The alternating-current motors must receive credit for the absence of commutators and consequent freedom from trouble due to this source, but they have not the adjustable speed characteristics of the direct-current motors and hence are not as well adapted to the operation of variable-speed machinery.

There are a number of shops entirely operated by alternating current where the speed adjustment of machine tools, having variable-speed characterisitcs, must be obtained with gear change devices. In the majority of the larger shops both alternating and direct current are used, the former being either

*Railway and Traction Engineering Department, General Electric Co.

purchased or obtained from prime generating units and the latter furnished by motor generator sets or rotary converters driven by alternating current. A number of shops, however, especially the smaller ones, are operated exclusively by direct current.

As a general proposition, under average conditions, the alternating-current direct-current combination is preferable for large installations; alternating current exclusivly for small shops where current is purchased from central stations, and direct current for small shops where current is generated on the premises. Where the alternating-current, direct-current combination is installed, the use of direct current should be confined exclusively to the variable-speed machine tools and alternating current should be used for the operation of

INTERIOR OF PORTION OF C.P.R. "OGDEN" SHOPS, CALGARY, ALTA.

transfer tables, cranes, turntables, etc., as well as for the constant-speed drives and illumination of the premises. Under these conditions, the proportion of alternating-current to direct-current generator capacity would be about three to one.

Compressed Air Feature.

In addition to the electrical energy requirements for railroad shops, a large quantity of compressed air is necessary for the operation of pneumatic riveters, drills, chipping hammers, etc., which are used in large numbers throughout the plant. It is also required in lesser quantities for numerous other purposes such as painting, glass frosting, sand hoisting, train testing, cleaning motors and machines, pneumatic hoists, etc. The air compressors, ranging in capacity from 500 to 3,000 cu. ft. of free air per minute, are generally placed in the main power house and are connected by pipes to the various outlets located in such a manner as to best fulfill the requirements of the service. These compressors are, for the most part, steam-driven but the growing tendency of railroad companies to purchase current from an outside source has created a demand for motor-driven compressors, the rotating element of the motor being mounted directly upon the crank shaft of the compressor and transmitting power thereto without the interposition of gears or belts.

Large Motor Driven Compressors.

There is a serious objection to large motor-driven compressors, however, due to the wide range of compressed air consumption which prevails in railroad shop plants. In the case of the steam-driven machine, the governing apparatus admirably controls the speed of the compressor to suit the existing demand but, with the motor-driven machine, the speed remains constant and a throttling suction governor or by-pass control relieves the machine when the compressed air consumption falls below the capacity at the fixed speed. This is not an economical arrangement from a current consumption standpoint, and the wear on the machine is practically constant regardless of the amount of air supplied.

In view of the large size of these compressor units, which require the supply of from 80 to 500 k.w. of energy, it would not be feasible to have them start and stop automatically with the rise and fall of air pressure. To overcome the objections cited, and also to reduce the losses caused by long lengths of pipe connecting the various buildings, there now seems to be a tendency to distribute throughout the various departments small air compressor units which have a capacity of from 50 to 200 cu. ft. With units of this size, the motors can be automatically regulated without imposing undue strains on the machinery or the transmission line.

The innovations noted, were not effected without radical changes in the operating organization. The division master mechanic, who formerly had exclusive supervision of the locomotives assigned to his division, was compelled to release his sovereignty during the time they were undergoing heavy repairs in the main shops, for these shops were governed by shop superintendents who were responsible only for the economical and satisfactory repairs to the equipment.

Shop Design.

The designs of the shops have not been symbolic of unity of sentiment with respect to the various features of construction. The greatest divergence of opinion existed with respect to the arrangement of tracks in the erecting shop which, it might be explained, comprises the keynote of the entire building arrangement and equipment. The longitudinal track design demands two cranes in the erecting shop, each capable of lifting one-half of the weight of a locomotive. The transverse track design requires only one crane of such capacity as to lift the entire weight of the heaviest locomotives in service. With the transverse arrangement, transfer tables were sometimes installed so that the functions of the cranes were limited to the hoisting of engines only after they had been placed on the track upon which the repairs would be conducted. The transfer table is not required if sufficient clearance between the floor and the roof trusses is provided to handle locomotives over each other for the length of the shop. It is not, however, entirely the personal preference of the engineer which decides the arrangement to be followed for, in some cases, the plan of the available land upon which the shops are to be erected proves to be the governing factor.

The locomotive repair shop capacity is generally stated with respect to the number of tracks or pits in a transverse erecting shop and in terms of the number of locomotives that can be accommodated in a longitudinal erecting shop. It is apparent that a certain approximate fixed relation should exist between the floor space required in the different departments and the number of locomotives accomodated in the erecting shop. This relation must be correct and the capacity of the machinery must be properly proportioned in order that maxi-

mum efficiency and consequently maximum output for the capital expended may be obtained.

Railroad Shop Output.

The output of a railroad repair shop is generally expressed by the relation between the number of locomotives which can be contained in the erecting shop and the number of locomotives repaired in each month, or is defined as the number of locomotives per pit per month. This figure will vary from 0.5 to 3.0, depending upon the average amount of repairs to be performed and the floor space together with the machinery available in the departments contingent to the erecting shop. It is clearly evident that the highest efficiency will be obtained, as well as the maximum output for capital expended, if the installed machinery is such as to enable the erecting shop to turn out the largest number of engines per unit of floor space.

It is not essential to combine the locomotive repair shop and car repair shop in one plant, and the tendency in recent years has been to separate the locomotive and car departments. From a labor standpoint, it is not desirable to operate jointly a car and a locomotive repair shop as dissatisfaction is likely to result between the lesser skilled and lower priced labor employed on the former and the more skilled and higher priced labor employed on the latter.

The Steam Requirement Feature.

In contemplating the advisability of purchasing current from central station plants for driving the shops, the question arises as to whether or not the operation of high-pressure boilers can be discontinued when steam for running the generating units is not required. The stumbling block to the discontinuance of high-pressure boiler operation has heretofore consisted of the steam hammers in the blacksmith shop. These could not be economically operated by compressed air under the existing conditions. A recent design, covering a motor and air compressor combination which forms a part of the hammer equipment and furnishes compressed air instead of steam to the hammer cylinder, may overcome this contingency. The use of steam will generally be required for shop heating in winter and also for heating the lye vat solution during the entire year. These conditions can best be fulfilled by the installation of low-pressure boiler units of suitable capacity to take care of these requirements.

Future Development.

We are now confronted with questions respecting the future development of the locomotive repair shop. Will further progress be made or is the era of the steam locomotive rapidly passing, to be pointed out to the next generation as an ancient system of propulsion for railroad trains?

Few industries, if any, have been benefited to a greater extent by electricity than have the railroads. It is the agent that operates the signals which guarantee a safe passage for the trains; it operates the shops; it illuminates the shops and yards; it pumps the water to fill the tenders; and it propels the freight and passenger trains in increasing numbers every year. We can now purchase electric locomotives at a cost per pound less than twice as great as the cost per pound for steam locomotives and obtain from them a yearly mileage two times that of the steam locomotives which makes the net first cost of motive power approximately the same for a definite service.

Will the elaborate steam locomotive repair plants be superseded by more simple shops for the electric locomotives costing not more than one-fourth as much as the present steam locomotive shops? Will the average cost of repairs for electric locomotives, namely, 4 cents per mile as compared with the the average cost of repairs for steam locomotives of about 9 cents per mile, be a large governing factor in the future of the transportation problem? The next decade should provide the solution.

Oxy-Acetylene Process of Autogenous Welding

The subject matter of this article is taken from a paper read recently before the Institution of Naval Architects and from part of the discussion which followed. In view of the growing prominence of autogenous welding, considerable value attaches to the various observations.

THE oxy-acetylene process of autogenous welding which has been largely employed of late years, owing to the comparative simplicity and the facility with which it can be carried out, has a very wide field of usefulness. The oxy-acetylene blowpipe gives a flame producing a clean and easily controlled heat, which can be adapted to almost any position. The extreme adaptability of the process has tempted many to apply it without due regard to the whole of the conditions obtaining in practice, with the inevitable result that many cases of failure have occurred.

Several accounts of failures of boilers, valves, etc., repaired by oxy-acetylene welding have been published. The failures of boilers which have been published are not confined to cases of plates cracked in service and subsequently repaired by autogenous welding, the welded part having in turn given way, but cases of the seams of fire-boxes, and of the connection of crown plates to the cylindrical portion made by flame welding methods giving way, sometimes with disastrous results, have been recorded. In some of these cases, the welds were clearly defective owing to the presence of oxides, on account of an excessive proportion of oxygen having been present in the welding flame, or to the use of fluxes in insufficient amount, or of an unsuitable nature. In other cases, the welds have been imperfect and spongy, owing to the presence of gas cavities, or of particles of slag included within the metals.

In view of the fact that the welds which have failed, and of which particulars have been published, all appear to have been made by experienced operators, it is not surprising that in many quarters the oxy-acetylene and other hot flame autogenous welding processes are considered unreliable and viewed with suspicion.

Restrictions Enforced.

The Marine Department of the British Board of Trade have made rules and regulations fixing the limits to the use of such processes in boiler work, while the Government of Belgium has forbidden the use of autogenous welding in boiler construction, and in the case of extensive repairs. These restrictions, however, will probably be relaxed in the future, as the conditions affecting the strength and other qualities of the welded portion, in comparison with the original metal, become more thoroughly understood, and experience is gained of the behaviour of welded material under various practical working conditions. The writers consider that until results of such experience are available due caution should be exercised in the use of autogenous welding for boiler and high pressure work. As far as ascertained, the published results of investigations into the quality of welds made by fusion methods have, with one exception, dealt only with the changes brought about in the structure of the material, changes in the static tensile strength, and examinations for unsoundness and oxidation.

The authors, as the result of an extended experience in the testing of steel and other metals, fully realize that although the results of static tension tests frequently indicate that the weld is almost as strong as the unwelded material, they may be quite at variance with the results of dynamic tests or the behaviour

of the material in practice. Working conditions are usually such that the material is liable to repeated shocks, and in the course of their examinations, the authors made a large number of tests in order to compare the behaviour of the welded and unwelded material under repeated impact, and also to compare the results of such tests with the static tensile tests. A large number of welds of mild steel were prepared, and submitted to static tension and repeated impact tests, in the ordinary condition, and also after various treatments. The first series of tests were made on round bars of mild steel, containing approximately 0.25 per cent. carbon, five-eights of an inch diameter.

Results of Tests.

The tensile test bars were turned parallel for 1½ in. and of ⅜ in. daimeter, in order that fracture would take place in the weld. The elongation was measured on a 1 in. length, and it would appear from these results alone that an average weld might be expected to possess something like four-fifths of the strength of the unwelded steel, and that the ductility would be about one-fifth. The maximum strength in tension would appear not to vary to any great extent, but the ductility appears to vary considerably from the average, as the lowest strength recorded is practically 80 per cent. of the original material, and the lowest elongation only 9 per cent.

Hammering has increased the ductility and reduced the strength slightly, while reheating after hammering has produced a further increase in ductility, and at the same time increased the maximum stress. Again, reheating to the same temperature, without previous hammering, has produced a somewhat large increase in the ductility and a further small increase in strength; whilst in the case of the specimens quenched in water and then reheated, the strength has risen to almost that of the unwelded material, although the elongation has been reduced.

It appears from these results, and others which the authors have obtained, that under no circumstances does the ductility of the weld approach that of the unwelded portion.

A number of welded bars of the same material, tested under repeated impact, were prepared 6¼ ins. long and notched in the centre of the welded portion, the diameter at the bottom of the notch being four-tenths of an inch. The results of eighteen tests of welds after various treatments indicate that an average weld might be expected to withstand about half as much as similar material unwelded. Hammering has apparently been the most effective treatment so far as increasing the fatigue-resisting properties of the material, but it must be borne in mind that the heating during the welding is extremely local, and consequently the metal in the immediate vicinity of the weld is liable to be at a comparatively low temperature, and there is a danger, when hammering, of vibrating a portion of the metal when it is at a black heat, which, as is well known, is productive of brittleness. If hammering is resorted to, the metal should be reheated to a full red heat (800 deg. Cent.) in order to remove strains or brittleness which might be set up during the process. Reheating or annealing also appears to be of little value, so far as increasing the fatigue resistance of the welded portion is concerned.

Comparison of Results.

Comparing results, it is of interest to note that the form of treatment which gave the highest strength in tension has given the lowest result in the impact tests. The results given were obtained upon test through the centre of the weld and not in the weld itself. This is due to the fact that in heating to fusion the ends of the pieces to be joined, the neighboring metal becomes heated to a temperature sufficient to make it brittle. The actual weld where fusion has taken place has a structure characteristic of cast metal. The portion immediately adjacent to the weld exhibits a coarse meshwork of overheated, brittle metal.

The results of the repeated impact tests show very clearly that the thicker the plate the less reliable is the weld, and the greater the reduction in strength. Thick material also generally shows less improvement by annealing; in fact, under ordinary working conditions, it is usually impracticable to anneal the material. In consequence of the highly local heating action of acetylene, there is considerable danger of contraction stresses being set up in the metal, and undoubtedly this contributes to the greater reduction in strength of thick material.

The case of a welded plate only one-eighth inch thick came under the authors' notice some time ago. It was sent them to examine and report upon, with regard to the relative strength of the welded and unwelded material, by a firm of tank makers who had recently introduced acetylene welding of the seams instead of lapping and riveting. Transverse bending and tensile tests showed that the joint was stronger than the neighboring metal. The material being too thin to obtain ordinary fatigue test pieces, narrow strips were cut about half an inch wide, some with the joint running transversely, and some with the joint running longitudinally to the strip. The strips were placed in a vise and bent backwards and forwards through 90 degrees until fractured. It was found that the welded strips required at least as many right angle bends as similar strips of unwelded metal to produce fracture.

Unequal Cooling Effects.

The metal being thin, was quickly heated locally to fusion without damaging the neighboring metal, and cooling being rapid, the material in the neighborhood of the joint was probably in a much tougher condition than before the operation. The danger of stresses due to unequal cooling being set up would also be reduced to a minimum in such material. As the thickness of the plate increases, a larger portion of the neighboring metal becomes overheated, the cooling is slower, and the danger of contraction stresses being set up increases.

The authors, as the result of a large number of tests and experiments upon autogenous welds, conclude that, although there is a wide field of usefulness for oxy-acetylene and similar processes for joining or repairing steel plates, bars, etc., which are not required to resist very severe stresses, considerable caution must be exercised, and due regard paid to all the conditions before making use of them. A very serious responsibility attends the use of autogenous welding in cases where the parts are likely to be subjected to considerable mechanical strain. In any case, where failure tended to endanger life and limb, welds, if not entirely prohibited, should be accepted with extreme caution. Autogenous welds always represent a somewhat uncertain quantity, as there is no means, except by destructive tests, of ascertaining whether a weld is good or bad.

Uncertainty of Autogenous Welds.

Mr. J. T. Milton gave some very interesting and valuable experiences regarding the welding that was passed by Lloyd's Register. He said he gave his cordial approval to the fact that the Marine Department of the Board of Trade had made rules and regulations fixing the limits to the use of such processes in boiler work; and that the Government of Belgium had forbidden the use of autogenous welding in boiler construction, and in the case of extensive repairs. Autogenous welds represented an uncertain quantity, and there was a serious responsibility attending them, which called for the greatest caution in their use.

After a very big experience with welds, Lloyd's Register had adopted that policy. Great pressure had been put upon them to accept repairs by autogenous welding, but they had not seen their way to accept them in cases where their failure would mean serious disaster. On the other hand, where failure would not involve disaster they had accepted hundreds of those repairs, and they had proved quite satisfactory. For the repair of shell plates and boilers of

ships they would continue to prohibit that method, just as they did for crank shafts and large and important forgings.

It was necessary, too, to be warned that there was always a certain amount of unreliability about autogenous welding.

While the experiments referred to in the above paper were made on small pieces, the results might be very different if they were made with repairs on long lengths of plating, where they could not get entire uniformity of stress across the structure. He felt certain that if the same experiments were carried out on a larger scale they would show less advantageously than on the small scale. Only a little time ago a vessel had to be repaired after smashing her stern frame in a collision, and the work was done by autogenous welding. On account of the element of doubt, however, the owners had the ship taken into dock and a new stern frame was fitted. Unfortunately those interested in autogenous welding would not accept the offer then made by Lloyd's to test that piece of repair work.

AGRICULTURAL MACHINERY IN RUSSIA.

RUSSIA, as a market for agricultural machinery has lately been engaging the attention of the various British consuls resident in that country. Although present disturbed conditions do not warrant any considerable extension of this trade, it yet has important possibilities, and is one that has a special interest to Canadians. In 1913 Canada exported to Russia $1,841,433 worth of agricultural machinery.

Details of the Trade.

The following details of the trade with Russia in agricultural machinery are from a report by the acting British Consul-General at Odessa:

The demand for up-to-date labor and time-saving agricultural machinery of foreign manufacture increases annually. The local factories are so occupied with the manufacture of small and simple machines that they are unable to devote their energies to the installment of plant for the manufacture of more complicated machines, apart from the fact that they lack proper systems of economical production. United States manufacturers retain about 90 per cent. of the trade in self-binders and reapers, the balance being made up of Canadian, United Kingdom and German makes, of which the last bear an infinitesimal proportion to the total. A large American syndicate controls the market in these machines, making it almost impossible for the smaller producers to compete.

Thanks to United Kingdom manufacturers having fallen into line with their competitors in the matter of giving credit extending over three years, they have regained the prestige which they lost some few years ago, and the sales of British threshing machinery have now reached record figures. It is remarked that purchasers invariably give the preference to British threshing machinery, as on account of its greater weight it is more economical and durable. United States firms have tried to enter the market, but have met with little success. Many of the Russian factories are making small-sized horse and motor-driven threshing machines, and the motor-driven variety may in course of time seriously affect the sales of steamdriven sets.

American and German manufacturers hold the trade in seed drills and corn planters, but large quantities are now being made by local factories.

Harrows of the disc pattern have met with the approbation of purchasers, and are supplied by United States, Canada and German firms.

Germany continues to do a good business in the better classes of ploughs, both single and multiple, and the United States are also competing to a small extent. The bulk of the single ploughs sold, however, are of local manufacture.

The better qualities of chaff and root cutters are imported from the United Kingdom and Germany, but local factories are manufacturing inferior qualities in large numbers.

B. C. MANUFACTURERS' ASSOCIATION.

AT the annual meeting of the B. C. Manufacturers' Association held at Vancouver on September 2, the following officers were elected for the ensuing year: President, K. J. Morrison, Vancouver; vice-president, J. A. Cunningham, Vancouver; vice-president for Vancouver, H. H. Welsh; for Victoria, Mr. J. C. Pendray; for New Westminster, J. R. Duncan; honorary treasurer, E. G. Byres; chairman of committees; Reception and membership, H. Schaake, New Westminster; Vancouver, J. W. Curran; Victoria, W. H. Sweeney; tariff committees: Vancouver, J. H. Hanbury; New Westminster, W. R. Gilley; Victoria, H. Pendray; railway committee, Vancouver, J. Ramsay, Victoria, A. M. Kirk; New Westminster, W. L. Darling; parliamentary committee: Vancouver, Geo. Trorey; Victoria, G. A. Kirk; New Westminster, N. Nelson; commercial committee: Vancouver, E. B. McMaster; New Westminster, J. Reid; Victoria, Mr. S. R. Newton; press and advertising: New Westminster, W. L. Darling; Victoria, H. R. Houston; Vancouver, Harry Duker; vigilance committee: Vancouver, J. H. Hamilton; Victoria, W. A. Jamieson; New Westminster, A. Wilberg; insurance committee: Vancouver, W. H. Leckie; Victoria, T. M. Brachan; New Westminster, E. B. Davis.

THE IDEAL RAILROAD SUPERINTENDENT.

F. D. Undedwood, president of the Erie Railroad, gave the American Association of Railroad Superintendents at its recent Chicago meeting his opinion of what a real superintendent should be. His letter to the association was read by the secretary, E. H. Harman, of St. Louis. "A retrospect," said Mr. Underwood, "shows me that I fell far short in all the essential qualifications I now attempt to portray. Even now I would like another chance on a red-hot division to prove I could be a better superintendent than I was." Here are some of the things Mr. Underwood impressed on the superintendents:

A superintendent should not do physical acts that can be done by some one else. The bawling and hauling we old-timers did is unwise from several points of view.

A man who is never angry is not an efficient boss; the spur of anger should be concealed and used only to stimulate the stroke—never paraded.

There are in all walks of life those who bluster, plead, lie, and bring pressure from many sources. The processes used to carry their point are ingenious, plausible, and persuading. Quietly sidetrack them when sure you are right; never willingly recede from a position that is fair.

Breaking a rule or doing something outside of the rules is many times an offence to be condoned, provided the offender has brains. His action showed him fearless and perhaps expedient. There are the seeds of a good man in every rebel. Mentally pussy-footed sort of men are not desirable. An argufier—sometimes called a sea-lawyer—has his uses.

Never condemn a measure you want to kill; praise it, tell in how many times and places it would be fine, then put in the local misfit color.

Buy in Canada. — The purchasing agents of the Grand Trunk and Grand Trunk Pacific railways have been ordered to buy everything required by these lines in Canada and Great Britain wherever possible. For some years past German firms have been selling the companies large orders of steel goods and other railway supplies and all orders outstanding have been cancelled.

PRODUCTION METHODS AND DEVICES

A Department for the Interchange and Distribution of Shop and Office Data and Ideas Evolved from Actual Practical Application and Experience

A READER'S APPRECIATION.

By J. S. Drysdale.

READ **Canadian Machinery** with interest every week, and like many others, I get some very useful ideas, which I always put into practice at the very first opportunity. I have put to the test the various hints and found them of good service, and feel that I should pass on my experiences to others; for although some may have tried them on their own account, and, like myself, have found them all right, numbers may never have thought of them. The accompanying kinks may be useful to my fellow-craftsmen.

Grinding Pump Valves.

Not long ago I had a small steam pump to repair, and as the valves were all in bad shape, I started to grind them, but found that the flour of emery was too coarse and was scratching the valve faces. As I could not get any finer emery in the factory, I hardly knew how I was going to get through with the grinding job; so when home for lunch, I took some Dutch cleanser back with me, with the idea of seeing how it would work on the brass, which, by the way, was very soft. In a very short time, it is my pleasure to state, I had the eight valves ground up in good shape and without a scratch.

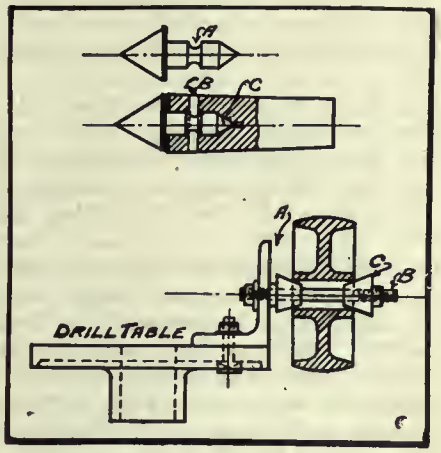
Hammer Heads Loosening.

I have often found trouble with hammer heads getting loose through the wedges coming out, and to overcome this I use a small steel burr on washer with a knife edge ground on it, and driven into the handle. On large hammers I use two washers. When the washer is driven into the wood handle it is there to stay, for as soon as it goes in, the wood closes into the hole of the washer, so that it cannot come out.

REVOLVING DEAD CENTRE.

By G. Barrett.

IN the accompanying illustration, the upper part, Fig. 1, represents a very simple and easily made form of revolving centre for the lathe tail stock which is particularly useful for small work, although it can be used to advantage on jobs of any size. A short time ago the writer had a large quantity of footsteps to turn for textile fly-frames. They were of annealed cast iron and the speed run for shimmering up caused them to run out at the centre through overheating. The trouble was gotten over by designing the revolving centre shown. This is made of cast steel and is bored about 1½ inch deep to accommodate the smaller piece as seen in the figure. This piece is also of tool steel and has a groove of ⅜-inch radius turned on the shank to accommodate a ¼-inch fastening pin and allow the necessary play. The groove is also used to carry lubricant, which is admitted through a hole drilled in the outer piece. As the centre revolves freely with the work, the latter revolves but does not heat and remains true. All wearing parts being hardened, the apparatus retains its true running qualities for a long time and will be found a great help in turning brass, wood and soft metals.



REVOLVING DEAD CENTRE.
WHEEL DRILLING FIXTURE

WHEEL DRILLING FIXTURE.

By G. Hamilton.

THE lower part of the above illustration shows a practical fixture for holding wheels, sheaves, pulleys and the like, while drilling oil or set screw holes. It consists of on angle bracket, A, to be bolted to the drill press table. It is fitted with a ⅞-inch stud of machine steel which carries the loose-fitting cone bushings C. Wheels of a wide range or size and bore can be quickly set up and rigidly held for drilling purposes.

By bolting the bracket to the table upside down, a much larger wheel can be taken under the drill and as many holes as desired can be drilled at one setting. Anyone who has worked in a number of shops knows something of the time lost in hunting blocks, packing, etc., to say nothing of broken drills now and then. The same principle can be used for drilling drums, drilling and tapping set collars and many other such jobs.

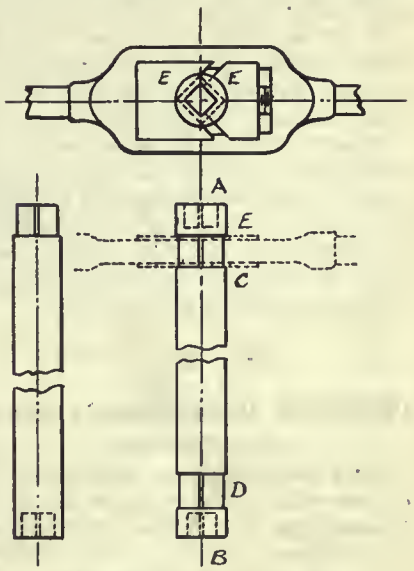
DOUBLE END TAP-EXTENSION.

J. E. Cooley.

A COMMON type of tap-extension made and in general use is that in the accompanying sketch. As seen, one end of the rod is milled square for the tap-wrench, and the other end has a square broach, in which to hold the tap. One extension is required for each size tap.

A suggestion for making one tap-extension serve for two different tap sizes is shown in Fig. 2. The ends A and B are broached out square, and on the outside of the rod, just below the depth of the broaches, as C and D, two places are milled square on which to fasten the tap-wrench. The jaws of the wrench are first opened wide enough to insert them over the end of the rod, and then closed up against the milled sides, as at E—E.

Formerly all wrenches were of the solid type having one size hole, and it was only then possible to use the single type tap-extension. The adjustable-jaw tap-wrench is now mostly used, and it is seen that tap-extensions can be double ended.



DOUBLE END TAP EXTENSION

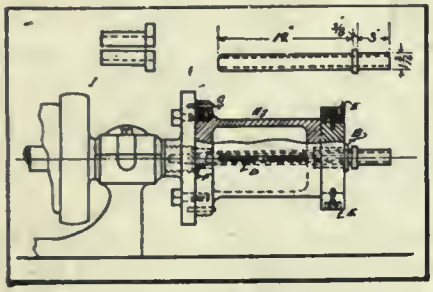
CHUCK FOR BORING LONG COLLARS.

By B. George.

THE boring of long collars with comparatively small holes is difficult, to say nothing of being very tedious. The writer has had them to do by the thousands, and has tried a great many schemes and devices for expediting the

work. The collars vary in size, being 1 3-16 diameter in the rough, the bores ranging from ⅝ in. to 15-16 in., and being 5 in. long over all. As they are annealed, they wear badly in the steady rest. They are unsatisfactory in other ways as well.

The chuck A, Fig. 2, is made of cast



CHUCK FOR BORING LONG COLLARS

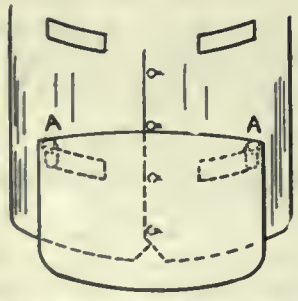
iron and is cored out, leaving ½ inch of metal after being turned. It is bored and faced to suit the mild steel bushing, which is shown in place at B. One of these bushings is made for each size of collars. The rear end of the chuck is faced and fitted with two ⅜-inch dowels C for locating on the face plate of the lathe. There are also two ½-inch slots D, the length of the chuck, and a steel ring made to fit the end E.

A special collet F is turned to fit the lathe spindle, and is bored taper to locate one end of the work, Fig. 1. The steel bushing B is split, which not only enables it to be tightened on the work by means of the set screws E, but it also clears the fins on the castings caused by the parting of the moulds. The boring is done with a flat drill at the rate of thirty per day, and the turning required is done afterwards on a mandril.

IMPROVED DRAFTSMAN'S APRON.

By "Hartford."

CONSTANTLY rubbing against the edge of the drawing-board wears away the front of the vest. A small apron to pre-



IMPROVED DRAFTSMAN'S APRON

vent this is worn by many draftsmen, being usually fastened on by means of tape tied around the back.

A more simple means for attaching one of the aprons is seen in the enclosed sketch. Two narrow strips of tin, as A-A, are bent in the form of clips and sewed on the back of the apron. These are slipped over the edge of the vest pockets and hold it on securely.

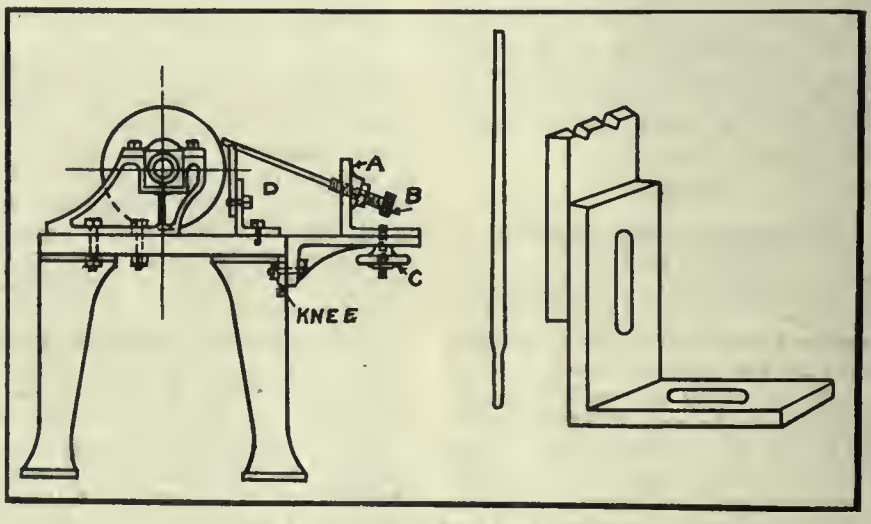
GRINDING MACHINE FOR TEXTILE SPINDLES.

By G. Barrett.

THE illustration shows a simple grinding machine for spinning mule ring frames and winding machine spindles. These are ground to a central point at the end to run in the footsteps of the above-mentioned machines. The end view indicates a spindle in the grinding position. The arrangement consists of a base plate 2 in. long, 2 in. thick, and 18 in. wide, with two brackets to form the bearings for the wheel spindle. There is also a knee piece cast integral with the base plate to accommodate the front bracket. This, in turn, supports the bracket A, which is of cast iron, and is drilled and tapped at an angle of 25 degrees to suit the screw B. The screw is centered for the top end of the spindles to bear against, while the bottom end is being fed against the wheel.

The rest D is a wrought iron bracket adjustable in two directions to accommodate wear of the grinding wheel. The two vees at the top serve as rests for the work. A larger view of the spindle to be ground is shown in the central part of the figure and the adjusting bracket is shown to the right.

By this arrangement and the clamping screw C, it is possible to get any desired angle on the spindle points, as well as to set up for any length of spindle. When



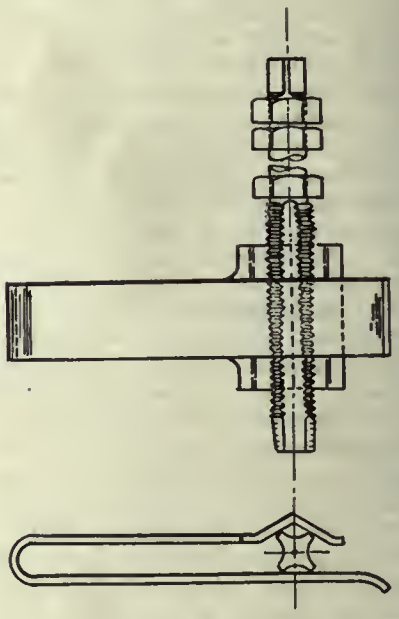
GRINDER FOR TEXTILE SPINDLES

arranged for a particular size of spindle, the speed and accuracy attained is very satisfactory, a boy being able to turn out an average of 13 gross per day.

NUT-TAP HOLDER.

By E. C.

WHEN taking a nut-tap out of a chuck in order to remove the tapped nuts from the end, it is necessary to use a small bunch of waste with which to take hold of the tap, as it is too hot to handle with the bare hand. This method has never been a desirable one, as the waste is soon soaked with oil, and the chips become imbedded in the hand.



NUT TAP HOLDER

A simple holder for this purpose is shown in the accompanying illustration. It is made from sheet-steel, cut out and bent in the shape as shown and then tempered, and forced over the threaded end of the tap; the tap being then removed from the chuck and the nuts taken off.

W. H. Connor who resigned his position as treasurer of the Pembroke Steel Equipment Co., has accepted the position of treasurer of the Flax Co., Ottawa.

NEW PROCESS DEVELOPMENTS

Inventive Genius and Research Operate to a Dual End — They Aim to Improve What We Now Possess and Bring to Our Service Commodities Before Unknown

TROPENAS CONVERTERS VS. ELECTRIC FURNACES.

AN interesting article on this subject appears in a recent number of Metallurgical and Chemical Engineering. The following claims are made for the electric furnace:—

(1)—The metal obtained is lower in phosphorus and sulphur contents than converter steel.

(2)—Segregation in electric steel is less than in converter steel.

(3)—Starting with cold steel scrap, electric steel is cheaper to produce than converter steel.

(4)—Absolute uniformity.

The author gives some interesting data in substantiating these claims. In the first place, the Tropenas process is by no means depreciated, and one would be led to think that the author's description of the simplicity of the process is somewhat over-rated. The advantage of the electric furnace in its capability to melt small scrap, borings, etc., is mentioned, whereby, although the electric furnace is not as efficient a melting furnace as a cupola, it can use cheaper raw material, and thereby offset the loss in efficiency to its adavntage.

Another interesting point noted is that, whilst a converter can be operated only once without great increase in the cost of production, the same cannot be done with the electric furnace except at great loss. In regard to the application of small furnaces of either type to the manufacture of large castings, the author is in favor of the Tropenas. He quotes an instance of an 8-ton casting being poured successfully with a single 2-ton converter. Six blows were made to secure sufficient metal, each blow being poured on to the top of the other in the ladle. It took 1 hour 45 minutes to make the steel, and no skull was left. This, of course, bears out the general practice that converter steel can be made very hot. Of the deleterious influence of sulphur and phosphorus, all steel casting manufacturers are well aware, and by the refining which is possible to the electric furnace this may be reduced to a minimum and the consequent troubles avoided.

ANNEALING MALLEABLE CASTINGS.

THE same journal contains an article by O. W. Storey on the subject of annealing malleable castings. The author deals with packing materials, temperature of annealing, time of annealing, rate of cooling. The iron experimented with had the following analysis:—

Total (combined) carbon, 2.60 to 2.70 per cent.
Silicon, 0.65 to 0.70 per cent.
Sulphur, 0.055 to 0.060 per cent.
Phosphorus, 0.140 per cent.
Manganese, 0.27 per cent.

Particular attention is given to the production of black heart castings, and it is shown that the packing material itself can influence the interior, but oxidising materials produce decarbonized skin, more especially if the material be loosely packed.

In regard to the temperature of annealing, it is found that with an annealing time of fifty hours this iron required an annealing temperature of 860° C. to secure a complete break-down of the cementite. Annealing at 750° for fifty hours resulted in a partial breakdown.

A quick rate of cooling after annealing results in a steely structure, and if the rate of cooling is sufficiently slow through the critical range, viz., 830° to 740°, all the carbon will be precipitated, while the rate of cooling below 740° has little effect. The time of annealing depends, of course, upon the temperature. The higher the temperature the quicker the anneal, although short anneals result in a poorer grade of material. The reactions of the annealing process have been studied, and the removal of carbon is attributed to the reaction between Fe_3C and CO_2., the resulting CO being then reoxidized and continuing the reaction.

The analysis of the gas taken from a sample being annealed at 870° contained 13.2 per cent. CO_2 and 26.8 per cent. CO, whilst a second sample taken from one annealing at 980° contained 4.6 per cent. CO_2 and 71.2 per cent CO.

TIN RECOVERY FROM TIN-PLATE WASTE.

THE recovery of tin from tin-plate waste has become quite an industry. There are three general methods of separating tin—mechanical, chemical and electrolytic. The most important of these methods is the last. The electrolyte employed is usually hot caustic soda; loosened chips of tin-plate packed in wire baskets acting as anodes, while the iron bath walls or iron plates suspended therein act as cathodes. The average tension is said to be 1.5 volts. When separated, the tin is spongiform. Other methods of electrolytic de-tinning are in use in Germany, among them an alkaline method which is said to offer great advantages over the acid methods formerly used, and a chloride method applied by Lambottle of Brussels; this is the most extensively used. The principal requirements for the successful application of it are absolute exclusion of moisture during the process of de-tinning, the avoidance of an unduly high temperature, and proper washing of the de-tinned waste.

MATHEMATICIANS THE FUTURE LEADERS.

Professor A. Ranum predicts that if progress continues along the lines followed, the pure and applied mathematics of to-day will surely lead, sooner or later, to a variety of practical applications and new inventions that will startle the world. The material and utilitarian progress of to-morrow will depend largely on the scientific progress of to-day. Moreover, the increasing demand for accuracy and efficiency in engineering can be met only by broadening and strengthening its mathematical foundations. Many an engineering student of to-day will live to see the time when those engineers who are leaders in their profession, who are capable of meeting novel conditions where originality of thought and action is required, will be men who are better equipped on the scientific side than we think necessary to-day; they will be men who are thoroughly trained in the use of many of the higher branches of what we now call pure mathematics.

Sir John Jackson (Canada) Ltd., have offered and placed at the disposal of the Ministers of Militia and Marine the services of the whole of their engineering staff, employees, plant and equipment, at Victoria, B.C., for any construction or other work, should they require such services for the defence of Victoria and vicinity. The firm employs a large staff of skilled engineers on the contract for the breakwater at the Outer Harbor, Victoria, and as the plant is most extensive and comprehensive, it is felt that, should occasion arise, the assistance which would be rendered the Militia and Naval Departments of the Government would be invaluable. In the building of entrenchments, the throwing up of defence works, the erection of additional forts and harbor fortifications generally, the service which the staff and plant of the company would perform would represent a tremendous asset to the Government.

Series of Practical Questions and Answers for Mechanics

Every care is being taken to include only pertinent, practical questions, and give same direct reliable answers. Catch questions will be avoided. Arithmetic, consisting of simple addition, subtraction, multiplication and division of decimals, will be found a most useful companion study, and should not be overlooked.

MISCELLANEOUS.

Question.—Wanted for actual tests, the comparative horse power for driving both high and low-speed blowers of the same capacity, the blowers to be used for collecting shavings in a planning mill.

Answer.—With the same blast areas, high and low-speed blowers of the same capacity will require the same horsepower. Low-speed blowers generally have larger blast areas and consequently larger exhaust pipes. This avoids the back pressure, in a small exhaust pipe, which is one of the chief causes of increased horse-power.

• • •

Question.—With an elevator of one-ton capacity and a total distance to be lifted of 150 feet, which would be the more economical to operate, an elevator to be lifted the 150 feet in one minute, or one to be lifted the 150 feet in two minutes? The motor would, of course, have to be larger for the one minute work, but it would need to be used only half as long.

Answer.—The amount of current per car mile for a one-ton elevator would be about the same at 75 feet and 150 feet per minute, which are moderate speeds. If higher speed were used, the consumption per car mile would be materially increased. Like other apparatus, there is an efficient speed for which the elevator is designed to operate; an increased speed will require power to overcome the increased inertia and decreased speed will waste power in added gear reduction.

• • •

Question.—A steel stack is 50 feet high, and is mounted on a base 10 ft. high. Twenty feet from the top is a ring, to which are fastened four guy cables. If these be attached to the ground 45 ft. from the base, how many feet of cable will be required?

Answer.—The height of the ring to which the guy ropes are attached above the ground is $50+10-20=40$ ft. The length of one cable is $\sqrt{(40^2+45^2)}=\sqrt{3625}=60.24$ ft. Four cables would require $60.24\times4=240.96$ ft.

• • •

Question.—An ash hopper is shaped like an inverted pyramid. The length of one side of the top is 12 ft. and its height is 14 ft. How many square feet of steel plate will be required, and how many cubic feet of ashes will it contain when filled to within two feet of the top?

Answer.—To find the area of a triangle, multiply the base by half the height. The base, in this case, is 12 ft. and the height is the hypotenuse of a triangle, whose height is 14 ft., and whose base is 6 ft. The height then is $\sqrt{(6^2+14^2)}=15.23$ ft.

Area of one side is $\frac{12\times15.23}{2}$. Area of four sides is $\frac{12\times15.23\times4}{2}=365.52$ sq. ft.

The volume of the hopper is the area of the base multiplied by one-third the height, and the length of a side of the base two feet from the top is a case of proportion, or is $\frac{12\times12}{14}=10.28$ ft.

Area of base $=10.28\times10.28=105.67$, and volume of ashes contained is $\frac{105.67\times12}{3}$ $=422.71$ cubic feet.

• • •

Question.—What would be the cooling surface of a surface condenser having 7,020 tubes, each 0.75 in. in diameter and 14 ft. long? Allowing 3.5 sq. ft. of cooling surface per kilowatt, what capacity generator could be served by this condenser?

Answer.—Circumference of one tube is $0.75\times3.1416=2.36$ in. Surface of one tube $=14\times12\times2.36=396.48$ sq. in$=2.75$ sq. ft.

Surface of 7,020 such tubes is $70.20\times2.75=19{,}305$ sq. ft. Capacity $=\frac{19305}{3.5}=5515.6$ kw.

• • •

Question.—In the above problem, at a steam consumption of 12.8 lb. per kilowatt-hour for the turbine, how many pounds of steam would the condenser handle per hour?

Answer.—$5515.6\times12.8=70{,}599.68$ lb.

• • •

Question.—What would be the radiation loss in B.t.u per year from a steam pipe 6 in. in diameter and 40 ft. long under 150 lb. steam pressure?

Answer — Experiments have shown that the radiation loss of steam pipes is 3 B.t.u. per hour for each degree difference in temperature between the pipe and surrounding air. Taking the average temperature of the air at 80 deg. F., and considering that the plant runs 24 hours per day for 300 days, and assuming outside diameter of pipe to be 6⅜ in., surface of pipe $=\frac{6.375\times3.1416\times40}{12}$ $=66{,}759$ sq. ft.

Temperature of steam at 150 lb.$=366.5$ deg. F.

Difference between temperature of steam and air is $366.5-80=286.5$ deg.

Loss per year $=286.5\times66.759\times300\times24$ $=137{,}714{,}328$ B.t.u., or the total heating value of $\frac{137{,}714{,}328}{14{,}000}=9{,}837.45$ pounds, or about 5 tons of coal.

• • •

Question.—How many gallons of gasoline could be stored in a bumped head cylindrical tank 6 ft. 8 in. long, with an additional spherical rise of 4 in. in each head and an inside diameter of 3ft. 6in.?

Answer.—Volume of the cylindrical part is $42\times42\times.7854\times80=110{,}835.65$ cubic inches.

To find the volume of a spherical segment, add three times the square of the radius of the base to the square of the height. Multiply the sum by the height and by 0.5236.

The volume of the two spherical ends is, therefore,

$[(21^2\times3)+(4^2)]\times4\times0.5236\times2=5608.8$ cubic inches.

Volume of tank $=110{,}835.65+5608.8$ $=116{,}444.45$ cu. in., or $\frac{116{,}444.45}{277{,}274}$ $=419.96$ gals.

• • •

Question.—A flywheel has an outer diameter of 124 in., the rim thickness is 5 in., and its width is 16 in. What would be the weight of the rim? If it were discovered to be 2¾ pounds out of balance, how many 1½-inch holes, 1½-in. deep, would have to be drilled in the heavy side to bring it right?

Answer.—Mean diameter$=119$ in. Volume $=5\times16\times119\times3.1416=29{,}907.032$ cubic inches.

Weight $=29908.032\times0.26=7776.088$ pounds.

Volume of one hole $=1.5^2\times7854\times1.5$ $=2.05$ cu. in.

No. of cu. ins. required to make 2.75 pounds $=\frac{2.75}{.26}=10.57$

No. of holes required $=\frac{10.57}{2.05}=5.15$

MARINE AUXILIARY EQUIPMENT OF CANADIAN MANUFACTURE.

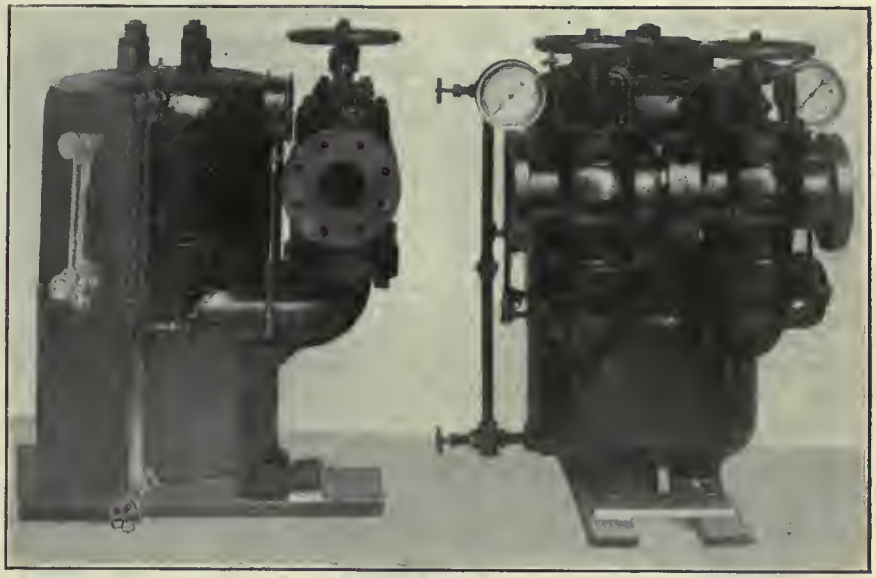
A new and interesting development following the growth of Canadian shipbuilding is the establishment of manufacturing plants for marine auxiliaries. Needless to remark, it is quite important for the makers of auxiliaries to be in close touch with the shipyards and vessel owners in order that the most suitable style of equipment may be offered for each vessel and spare parts furnished at short notice.

The Canadian Griscom-Russell Co. has been manufacturing for some time in their shops in Montreal the complete Reilly line of marine specialties such as feed water heaters, salt water evaporators, filters and grease extractors, along exactly similar lines to those by the Griscom-Russell Co., New York. One of their recent contracts was for two No. 47 Reilly multicoil feed water heaters with by-pass for installation on the dredges of the Canadian Stewart Co., operating in connection with the Toronto Harbor Improvement. The accompanying illustrations show the size and construction of these heaters. The heating surface consists of 47 coils of seamless copper tubing rolled into coils of small diameter. These coils are connected to the top and bottom manifolds with copper to copper unions which require no packing and allow easy removal of any coil. The large door in the heaters gives ready access to heating surface for inspection. These heaters are undoubtedly the largest marine feed water heaters ever built in Canada.

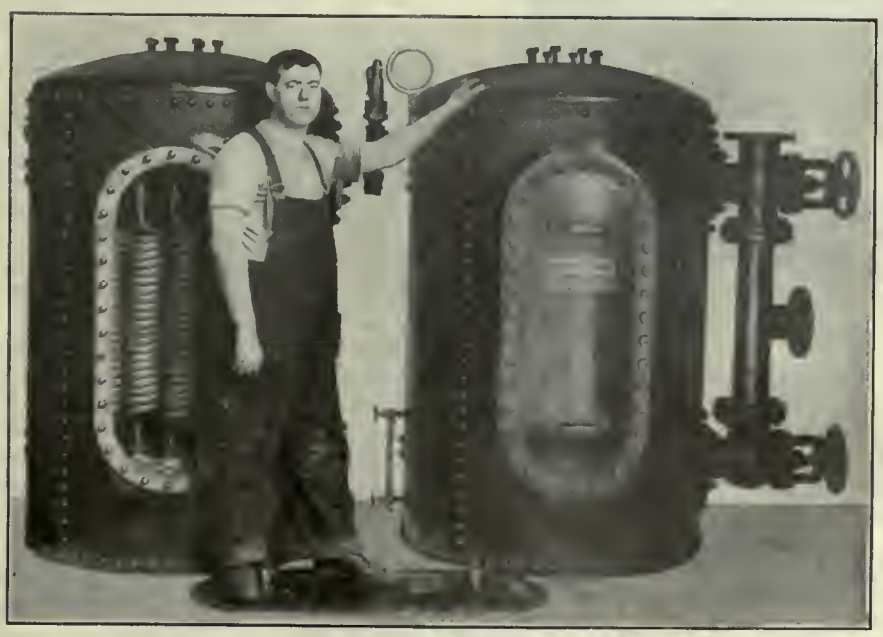
A high temperature of feed water is secured by the water passing through the coils whose small radius breaks up the column of water and thereby increases the efficiency of the heating surface. A number of these heaters of smaller sizes have already been built to Government and private order.

The Canadian Stewart dredges are also equipped with two 4-in. Reilly multi-screen feed water filters and grease extractors, their general construction being shown in the illustration. The filtering surface consists of heavy Terry cloth, being something in the nature of thick Turkish towelling. On large dredge work, it is especially desirable to have an efficient filter so that the boiler feed water be free from sand and other impurities stirred up in the surrounding water by the action of the dredge, and as surface condensers are usually installed on large dredges it is important to have an efficient grease extractor to remove oil and grease from the water in the hot well before feeding the condensate to the boiler.

An essential part of any filter is accessibility to the filtering medium and simplicity in cleaning. This cleaning is accomplished in the Reilly filter by a large bottom blow-off for the heavy precipitate and surface blow-off for oil and grease. An internal steam cleaning connection is provided so that the filter may be by-passed and the filtering surface boiled out without removing the cartridges. When it is desired to remove the cartridges, they are readily withdrawn through a large manhole in the top of the shell and may be boiled in soda for a thorough cleaning of the filter material. These filters are usually built for high pressure service, being placed between the feed pump and the boiler. In some cases, however, they are designed so that the water is cleaned of sand before passing through the feed pump.



TWO 4-IN. REILLY MULTI-SCREEN FEED WATER FILTERS AND GREASE EXTRACTORS.



TW ONO. 47 STANDARD REILLY MARINE FEED WATER HEATERS WITH BY-PASS VAL VES.

Locomotive Superheater Regulating Valve.—It is proposed by a South American engineer that in a locomotive superheater of the fire-tube type the regulating valve should be placed on the outlet side of the superheater instead of the inlet side. The superheater consists of a header with two chambers connected by tubes, and the regulator valve slides on seatings in a chamber on the outlet side. The valve rod passes through a cylindrical boss in the partition between the saturated and superheated steam chambers, and it fitted with a piston to make a steam-tight joint. The valve consists of two parts, one sliding inside the other and pushed outwards against the seatings by a spring.

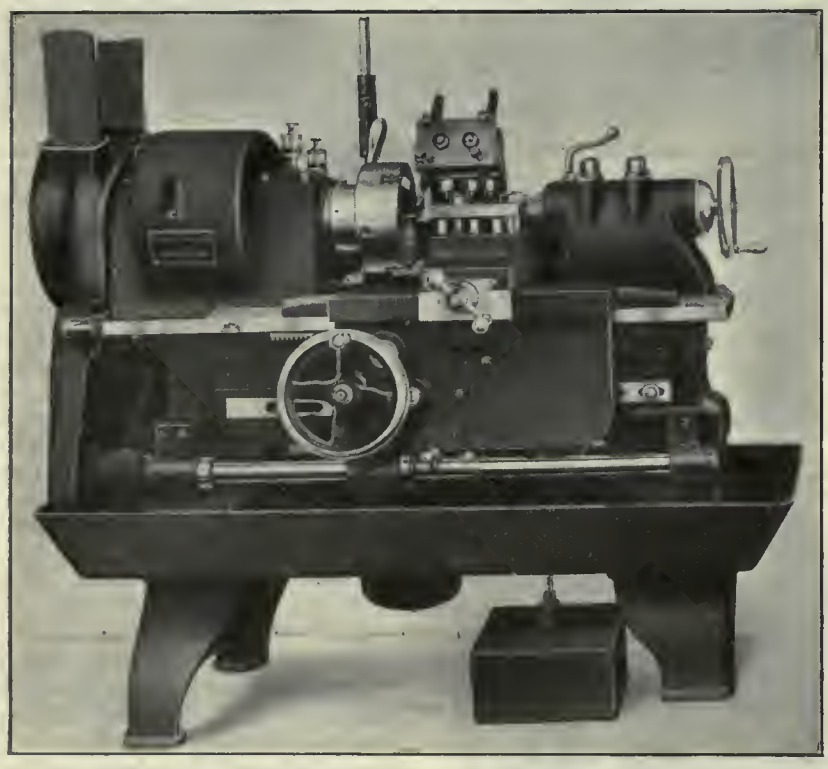
PROGRESS IN NEW EQUIPMENT

A Record of New and Improved Machinery and Accessories for the Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

AUTOMATIC LATHE FOR STRAIGHT TURNING AND FACING.

THE lathe shown in the accompanying photograph is extremely rugged, being generally heavier than ordinary machines of its type or capacity. It is built throughout on 20-inch. heavy duty lathe lines to insure absolute absorption of vibration, and to withstand the severest service. The power is also in excess of any demand likely to be made upon the lathe. The wide double belt drives to a large diameter pulley, then through a pair of herringbone gears (running in oil) to main head spindle. This arrangement gives a constant spindle speed, no mechanical changes being provided.

A feature of these lathes is the one feed and the one speed idea, thereby guaranteeing a maximum production when machine has been set at proper feed and speed for a given operation. Change gears can also be used if desired to vary the feed to suit the class of work, although, when once set up, the feed is rarely changed. In order to obtain the desired spindle speed, the countershaft speed must be changed accordingly.



AUTOMATIC LATHE FOR STRAIGHT TURNING AND FACING.

The object of this tool is to furnish a second operation machine that will produce a large quantity of work, and which will be equal in quality to that produced on the very best type of engine lathe. In the construction careful consideration has been exercised in the distribution of material, combined with the highest class of skilled workmanship.

The head spindles are made of chrome nickel steel, heat treated, while the bearings are hardened, and run in phosphor bronze journals. Sight feed oilers are used for lubrication of all head bearings. The driving pulley which is mounted on a shaft at rear of head, and which arrangement eliminates all belt tension on the main spindle, is well guarded to protect the operator, the same guard covering all end works gearing.

The tailstock is extremely rigid, being of the four-bolt type. It is made in one piece in preference to the regulation two-piece tailstock, as this feature tends to prevent any chance of side-ways shift of tail spindle. The carriage and apron are also heavily constructed, the rack pinion being made of hardened steel, engaging with a hardened rack on bed.

A cam feeding-in attachment is incorporated in the construction of the apron and carriage, constituting an adjustable bracket on the side of the bed carrying cam surfaces; and a link motion inside of the apron that transmits a cross feed action to the front tool block. The longitudinal travel of the carriage causes the link motion and cam surfaces to deliver this feed-in motion to the block, feeding the tools into the work to a predetermined diameter.

The back arm facing device is an attachment mounted on a large shaft or bar, which bar is supported in bearings cast integral with the head and tailstock, and bored in perfect alignment with the main spindle. A cam attached to the rear of the carriage actuates the bar by means of a roll carrier arm, which projects from the bar, and is in contact with the cam surface. The longitudinal travel of the carriage which carries the rear cam, causes a rotating motion to the bar, which feeds the facing tools in toward the centre of the spindle. It will be noted that the longitudinal travel of the carriage actuates both the feeding in of the front tools, and the feeding in of the facing tools. When the work is completed, the feed is automatically tripped, and the carriage and all tools almost instantly return to their starting position.

The complete cycle of operations on a piece is as follows:—The work mounted on an arbor is placed between centres, the countershaft started, and the feed-latch lifted into position. Both feeds are thus started, the work progressing until all diameters are turned and all shoulders and ends faced down, after which the feed is automatically tripped and all tools return to their starting position. This completes the cycle of operations, and the machine is then ready to receive another piece which has already been pressed on another arbor. Thus it will be seen that it is quite possible and practical to permit one operator to have charge of two or more machines. It will be noted from the cut that the entire machine is compactly designed, the idea being to eliminate any spring due to long arbors or excessive over-hang of tail spindle. The floor space required is 5 ft. x 3 ft. 4 ins.

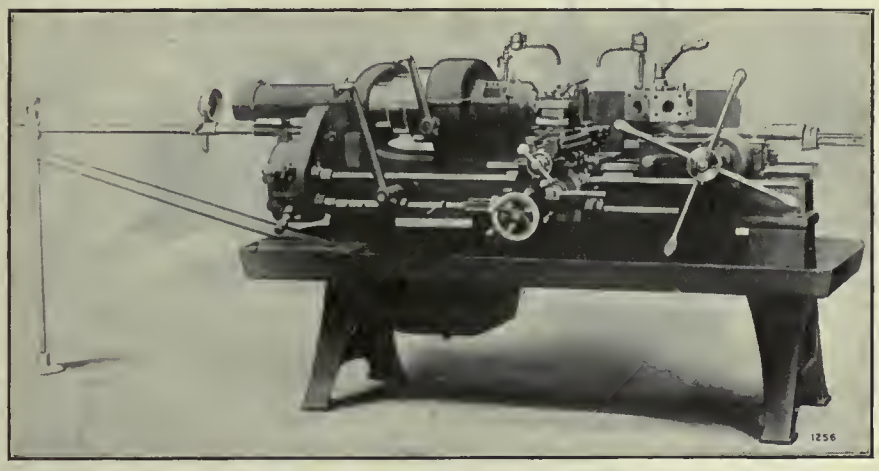
These lathes were designed specially for the Ford Motor Co. by the Reed-Prentice Co., Worcester, Mass., and have, we understand, greatly exceeded the expectations of the former company's mechanical experts in operation performance.

—⚙—

The Boving Co. of Canada, Ltd., Toronto, has been awarded a contract for two hydraulic presses for the Northumberland Pulp Co., Cambellford, Ont.

UNIVERSAL TURRET SCREW MACHINE.

THE Warner & Swasey Co., of Cleveland, Ohio, have put on the market what is known as their No. 4 Universal Turret Screw Machine. New features incorporated in this product consist of the power longitudinal feed for carriage, the arrangement of the carriage for chasing threads, and the fact that the carriage and turret are driven by separate shafts. These features add greatly to the efficiency of the machine and have been developed as the result of the company's wide experience in building turret screw machines.



UNIVERSAL TURRET SCREW MACHINE.

For a long time screw machines have been built with power cross feed on the carriage, but this is the first machine to be fitted with power longitudinal feed. In order to add to the possibility of working with the carriage, it is driven by a separate feed shaft. Another important feature is the fact that the feeds of this carriage can be reversed entirely independently of the feeds of the turret; thus, the turret can be fed toward the chuck while the carriage feeds away from the chuck if necessary. In this way, two diameters can be turned at once, or the outside of a piece may be turned with the carriage while the hole is being bored from the turret. The longitudinal feed to the carriage has six independent adjustable stops for gauging the length turned. These stops trip the power feed and act also as dead stops.

Referring now to the chasing attachment; by placing the chasing lever in its horizontal position, the chasing follower is brought into engagement with the chasing leader, and when the thread has been chased, the chasing lever is lifted, thus bringing the returning follower into engagement with the returning leader, and throwing the chasing follower out of engagement with its leader. As the returning leader and follower are threaded in a direction opposite to that of the chasing leader and follower, the carriage is thus returned to its starting point. It is not necessary to reverse the countershaft nor spindle for returning the chasing tool to its starting point. Each leader and follower cuts threads in multiples of 1 and 4 of its own pitch.

The turret slide has a length of feed of 10 inches, which is an extremely long travel for this size machine. It has also a very long bearing in its saddle. The saddle is provided with supplementary taper base, and this slide is fitted with taper gibs on each side, these being fitted for re-alignment of the turret after it has worn slightly, although in the ordinary course of events it will not be necessary to adjust any of these parts for quite a long time. The power feed to turret is through a taper friction instead of the ordinary form and worm gear.

Referring to the taper attachment, the cylindrical arm of this fits into a corresponding boss on the back of the bed, while at the other end of the arm is the T block. The base of the attachment bolts into the T slots at the rear of the cutoff slide, and to this base is fitted the tool-block itself, this being in turn operated by the taper bar at the back, this taper bar being adjustable for tapers up to 3 inches to the foot. In doing taper work it is not necessary to disconnect the cross feed screw, inasmuch as the taper is not obtained from the cutoff slide itself, but from the tool block of the attachment. This tool-block is arranged for either inside or outside tapers. The taper attachment does not interfere with the operation of the turret or square turret, and both cylindrical and taper work can be done on the same piece with the carriage without removing the taper attachment.

The machine can be fitted with geared head, may be driven by single pulley, or with the 3-step cone head—the latter being the standard. The automatic chuck and wire feed handle bar stock up to 1½ inches capacity. The machine swings 16 inches over the bed and 8½ inches over the carriage cross-slide; the total longitudinal travel of the carriage is 17 inches and the cross travel, 8 inches; and the longitudinal travel of the turret is 10 inches.

NEW TYPE HOIST.

A NEW type of hoist has recently been placed upon the market by the Ingersoll-Rand Co., New York City. It is intended for light lifting work, having a capacity up to half a ton, and, due to its light weight, which is under 300 pounds complete, it is particularly serviceable as a portable hoist for mines, for contract work, for manufacturing plants, for power houses, and in railroad shops and shipyards.

Manufacturing and power plants will find the device handy for moving light machinery and for hoisting ashes, waste material, and for loading trucks, freight cars, etc. It is a particularly desirable appliance for the foundry, where heavy weights have to be moved. In shipyards, in railroad shops and in connection with construction trains the hoist, which is known as the **Little Tugger**, can be put to innumerable uses.

The main base is arranged so that it can be bolted to a timber, and by means

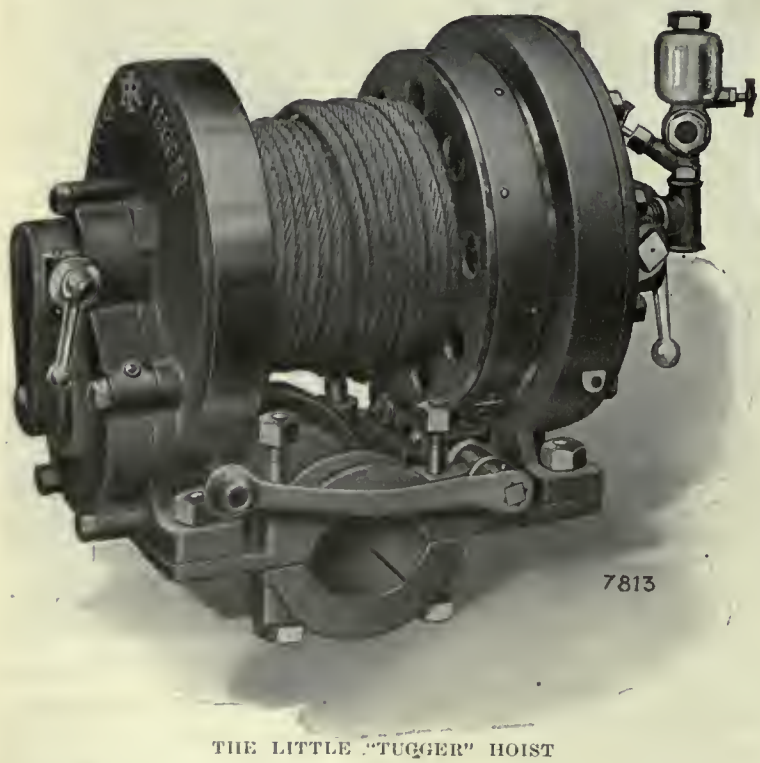
LITTLE TUGGER HOIST AT SHAFTHEAD

of a cap which accompanies the hoist, it can be clamped quickly to a circular member, such as a mine column or arm, shaft bar or pipe. The dimensions of the hoist are 21¼ inches by 16½ inches, and the height is 20⅛ inches. The drum is 6 inches in diameter, with a space of 7 inches between flanges. This accom-

modates a length of 700 feet of ¼-inch rope, or 450 feet of 5/16-inch rope. The capacity is 1,000 pounds at a rope speed of 85 feet per minute, and a pressure of 80 pounds. It operates with either compressed air or steam.

The motor or engine is of the reversible square piston type, giving four impulses per revolution of the engine. There are no dead centres, so that starting is possible in any position. The drum is mounted independent of the engine shaft, and is operated through the medium of a clutch and gears. Safety is secured by a powerful worm-operated hand brake lined with **Raybestos.**

Referring to the illustration, the engine is on the right and the gear case on the left-hand side, and between the two are the brake and drum. The lever on the left controls the gears and clutch, while that on the right controls the direction of operation. The bottom lever operates the brake. The speed of hoisting is entirely at the will of the operator, and when he releases the throttle, it returns automatically to central position, shutting off the power and stopping the hoist. Oftentimes the hoist will be used for haulage purposes, and the release feature enables one man to handle this class of work. He can leave the control lever and carry the rope to the car.



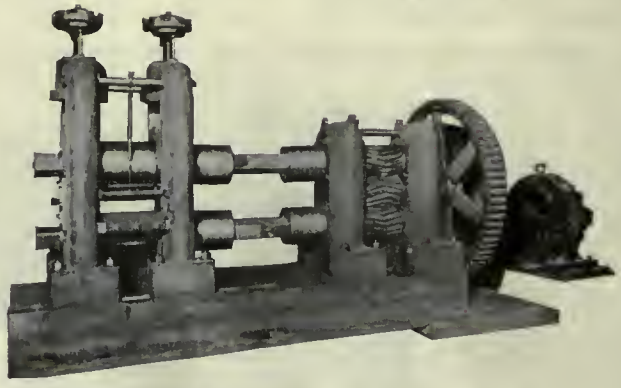
THE LITTLE "TUGGER" HOIST

There are no moving parts exposed except the drum, all gears and shafts being covered, an especially desirable feature for underground operation where the light is none too good, and where there is constant danger of workmen's clothes or bodies getting caught in the machinery.

MOTOR-DRIVEN ROLLING MILLS.

THE illustrations show two interesting types of rolling mill manufactured by the Standard Machinery Co., Providence, R.I. The direct motor drive shown has many advantages over belted drive from line shaft. In certain classes of work it is desirable to operate below full speed, therefore controllers are supplied with the motors shown, allowing continuous operation at any point between half speed and full speed of the rolls. Motor drive allows the placing of the mill to secure the most advantageous handling of material, regardless of the location of line shaft.

The large mill, which is driven by a 90 h.p., 850 r.p.m. Westinghouse Electric Co. alternating current motor, is used for the cold rolling of steel. The housing rolls are 11 inches in diameter, and 12 inches face, and the intermediate roll is 5 inches in diameter. The gearing is triple trained and is very substantial. The use of roller bearings effects a large saving in power. The mill is designed for economical operation and long wear in heavy service.



ROLLING MILL FOR COLD ROLLED STEEL.

The small mill, driven by a 3½ h.p., 1150 r.p.m. Westinghouse Electric Co. direct current motor, is for manufacturing jewelers' use. The hand wheels for setting down the rolls are equipped with micrometer adjustment for accurate work. The rigid construction and carefully cut gears insure the work coming out smooth and free from waves. With the motor located as shown, the entire outfit requires no more space than the rolling mill itself.

"IF I HAD MY WAY."

THE title of this editorial is intensely human, because of its universality, and because of the expressed sentiment being more or less personal to all of us. We have each wished to have things planned, ordered and carried out in accordance with our views and opinions, on occasion, forgetting meanwhile, if not altogether regardless of the effects on others, that our way in its individual essence would lead only to a dead end. In the spheres of politics, sociology, business and finance, the spirit of our title is everywhere rampant, and its practice is in part effected wherever possible, and would further if dare be. In a word, autocracy is a leading constituent of our mental fabric. Wilful Willie willed to have his way, but as many less prominent people have found, it has been determined otherwise, hence the all-European War.

We reckon, and judging from appearances that in the present instance are in no way deceptive, there has been a particularly strong inclination on the part of Canadian manufacturers to exercise what seemed to them a prerogative, to wit, to take no chances while the war lasts, or for the period, however indefinite, that surpluses were unlikely to materialize. In the case of employees too, there has been at this time a pronounced tendency in many cases towards resisting the installation of shorter hours of labor or of a remodelled remuneration system whereby not only more hands would find work, but there would be retained to and maintained for any particular enterprise or organization its personnel in expert efficiency.

In desiring our own way, we are consciously or unconsciously looking out for our little individual selves, and among the many lessons that are being and will yet be taught us by the relative effects of this European War in which we are involved is that, whether we be employer or employee, self-seeking or self-assertion at the expense of another or others—having our way, must be banished in every form and particular.

DISCOURAGEMENT OF INITIATIVE.

IT is an even chance that, be this European War long or short, the field for the development of Canadian, or for that matter the enterprise of the different countries now more or less on the qui-vive for its extension will after all be much the same as it has been, and that the actual lengthening of the cords of industry and commerce will be little, if anything, in excess of what would have been realized in normal times. The tightness of money will of course contribute largely to such an outcome, and being sufficient excuse in many cases for the other—lack of initiative—the net result cannot be much else than as you were.

Our whole social and industrial fabrics are simply bottled up in what we are pleased to call system, and we are patiently waiting until somebody comes along and uncorks us in the midst of to-hand opportunities. The rut of system has so far engulfed us that it seems well nigh impossible to get out of it to do pioneer work, which is both the call and the opportunity to-day.

No far-fetched reasoning is involved in diagnosing an employer's attitude towards the display of initiative from that of his employees, for initiative profitable alike to man and master can to some degree at least be practised by the former even in spite of the most iron-bound system and without upsetting same; yet if either because of pure "cussedness" or absolute lack of inborn or drummed-in intelligence, or both, men of this stamp are allowed to pursue their way unchallenged, then so far as initiative is concerned, we are justified in classing the employer with the employee.

Instead of fostering initiative in men, the tendency is to discourage and stifle it in business matters. We seem to overlook the fact that aside from the prescribed hours of labor, mental or bodily, during which we must keep to the track, there are hours as important not only to ourselves and our relations, but to those from whom we receive employment, in which initiative is especially demanded, and who shall say that its real effective exercise will be the outcome, if the major portion of a man's waking hours be put under a non-initiative ban.

The General Market Conditions and Tendencies

This section sets forth the views and observations of men qualified to judge the outlook and with whom we are in close touch through provincial correspondents.

RETURNING CONFIDENCE IS NOTED.

QUITE obvious signs of growing confidence have been noticeable during the week. Banks are inclined to freely lend money for strictly commercial transactions, but are, of course, endeavoring to avoid every kind of speculative business, even if that business is to be found in manufacturing and jobbing. Factories who find it possible to dispose of their output will not suffer from lack of banking accommodation. Enquiries warrant the opinion that the banks are now doing their utmost in this direction.

Montreal, Que., September 14. 1914.—Business still continues to go on much as it has done during the last six weeks. Small hand-to-mouth orders seem to be still most prevalent. No large orders are coming in, and with the banks handling their end of the business admirably, the small volume of trading is being done very smoothly. Deliveries of British goods are being received from time to time and although deliveries are not being guaranteed, shipments seem to be arriving with more or less regularity. Recent reports from England state that but 2.6 per cent. of the male population are unemployed, and if such a condition be existent, it is certainly up to us here to emulate it.

Steel Market.

No change has taken place during the past week. Quotations vary from different mills, but taking conditions all around, the prices are very firm. A large falling off in contract work is to be noted, most orders being of the small variety. A brisk business is however being done.

Pig Iron.

Although the European pig iron supply has been cut entirely, no great inconvenience is meantime felt as a number of Canadian foundries are operating at a reduced output. Prices remain firm, however.

Machine Tools and Supplies.

The outlook for machine tools and supplies is not over bright. Sales of late having been somewhat scattered. The demand for supplies still keeps up.

Metals.

The idea that Britain would require more or less of her supply of metals from America, and also the uncertainty in regard to the delivery, caused most metals to go up in price considerably. As conditions are being better understood prices are again dropping to normal.

Toronto, Ont, Sept. 15, 1914.—There is no appreciable change in business conditions this week, but a more optimistic spirit is noticeable. The community is rapidly adapting itself to the war conditions, and getting over the uneasiness which prevailed. The decided improvement in the news from the front is also having a beneficial effect, and is helping to dispel some of the gloom which previously overshadowed everybody to a greater or less degree. Prospects generally are more reassuring, and a continuation of successful military operations will do much to improve the financial situation and relieve the nervousness in business circles. With a greater feeling of confidence, combined with courage, trade should show considerable improvement when money is easier to obtain. Some industries are doing well as a direct result of the war, while others are not so fortunate; the former, however, help to improve the industrial situation as a whole.

The future for trade looks promising. There are greater possibilities for opening up new markets and introducing new industries in Canada, an opportunity of which full advantage should be taken. The splendid way in which Canada has come forward with men and material in

aid of the Mother Country during the crisis has created an impression in the Old Country that will not readily be forgotten. The enhanced popularity of Canada in Great Britain on this account and the gratitude shown by the people will be a great factor in stimulating trade, especially when the war is over. British capital will flow into this country for the development of natural resources and industries to a greater degree than was ever before experienced.

Steel Market.

There is little or no change in the iron and steel markets this week, conditions generally being the same, for although the outlook is brighter, this is largely of a sentimental nature. The difficulty of financing new building projects is being felt, and few orders are being placed for structural material. The same remark might apply to almost all lines, for conditions are practically the same. Although it has been reported that the C. N. R. has been successful in obtaining a loan in London, no statement has yet appeared with regard to the expenditure of the money.

All our steel mills have either curtailed operations or closed down entirely. Although they are endeavoring to get in touch with new business, it will be some time before the possibilities for expansion of trade in this direction take definite shape. There will no doubt be an increased demand from foreign markets for steel products formerly supplied from Europe, but how far Canada will benefit, providing the mills can supply the market, remains to be seen. We understand that Canadian manufacturers of wire nails have received a large number of inquiries from England for these goods.

New home business in the United States has fallen off, and the export trade has not developed as fast as was expected, although it is anticipated that this will eventually increase as the result of the war. A tendency towards a quiet market is looked for during the remainder of the year. Prices are firm, and no changes have to be recorded. The ferro-manganese situation is easier. A considerable quantity has been shipped from England, and the United States Steel Corporation is reported to be selling this material at $85 a ton.

Pig Iron.

Little business is being done in pig iron, and the few sales being made are for small tonnages. During the month of August over 46,000 tons of iron ore was received at the Victoria Furnace, Port Colborne, Ont., for stock.

Machine Tools.

Business in machine tools is slow, although dealers report quite a few sales. Little improvement can be expected, however, until conditions improve and money is easier.

Machinery Supplies.

There is not much business being done in machinery supplies, and prices as a rule have not changed; the exception being belt lacing, which has been advanced 10 per cent.

Metals.

The metal markets generally are quiet, and only a moderate amount of business is passing. The copper market is dull, and prices have declined. Tin is weaker again, and is now being quoted at 40c. Shipments of this metal are being made from London. Antimony is dull, and has dropped to 16c. Other quotations are unchanged.

CANADIAN IMPORTS OF IRON AND STEEL GOODS, HARDWARE, ETC.

PERHAPS one of the most widespread effects of the present war on the Canadian import trade will result from the cutting off of the supplies of iron and steel goods, hardware, etc., that have been coming from Germany. For the year ended March 31, 1914, iron and steel goods amounted to $2,824,900, or nearly one-fifth of the total import of German goods into Canada. A great assortment of goods goes to make up this amount, among them being included tubing to the value of $539,130, and steel tires for locomotives, etc., to the value of $348,059. Of special significance are Canada's purchases of cutlery from Germany, which amounted for the year concerned to $379,890. This is second only to the imports of cutlery from the United Kingdom, and exceeds those from the United States by over $150,000. German machinery was last year bought by Canadians to the extent of $252,689, while other iron and steel goods imported included wire of a value of $140,523; angles, beams, etc., worth $185,138; billets to the extent of $68,728; tools and implements worth $66,724, and iron and steel ware proper to the value of $93,037. This great assortment of goods being no longer obtainable from Germany, it rests with the Canadian iron and steel manufacturers to see that a large proportion of them are supplied at home.

A great quantity of small hardware has been exported from Germany to Canada every year. The Canadian tables do not enumerate the specific articles of hardware imported except in the case of iron and steel goods. The following figures, however, of the principal metals and manufactures thereof, other than iron and steel, imported from Germany last year, will give some idea of the extent of the import trade in German hardware. The figures are comprised in large part of finished manufactured products:—

Metal.	Value.
Brass	$130,389
Zinc	108,736
Copper	52,206
Tin	29,763

FOSTERING BRITISH TRADE.

THE British Trade Commissioner's office at Montreal is making an effort to enable importers of German goods to duplicate their requirements in the United Kingdom market, and C. Hamilton Wickes, the British Trade Commissioner there, states that he will be pleased to receive samples of any goods which had been imported by Canada from German or Austrian markets, so as to secure quotations for articles of a similar nature from the United Kingdom for importers requiring same.

In this connection, it may also be well to mention that there are many firms holding German and Austrian agencies in Canada who will be obliged to sever their connections, and if they desire to secure British representation to replace the foreign representation at present held, they should make application to His Majesty's Trade Commissioner, 3 Beaver Hall Square, Montreal, Que.

RE-OPENING OF PLANTS.

THE Standard Chemical, Iron & Lumber Co. have made the following announcement:—

The company has altogether fifteen plants, twelve of which are located in Canada, one in Germany, one in England and one in France. As a result of the war a serious dislocation of the company's business was anticipated owing to the fact that they exported largely to England, and also large quantities of crude alcohol to France and Germany. All the Canadian plants were therefore shut down immediately except the Longford and Fasset, Que., plants.

"During the past few weeks we have succeeded in making important contracts in England for next year's delivery, and have also been able to liquidate our stocks there owing to the complete shutting off of the continental supply of wood chemicals. We are therefore proceeding to open up our factories, having now started our Cookshire factory, and anticipate opening our largest plant at Sault Ste. Marie about October first. The other factories will be opened up gradually and early next year we anticipate running to full capacity. The moratorium in England is not being taken advantage of to any extent as far as we are concerned."

THE PATENT SITUATION.

PATENTS and trade-marks granted to a subject of any state with which Great Britain is at war are not declared to be void, but may be voided or suspended in whole or in part on application to the Board of Trade. The applicant must put up a fee of ten dollars with the application, and a fee of 60 cents for depositing foreign documents or other papers for purposes of record. The Board of Trade may then suspend or void the patent in whole or in part if it appear that the person applying intends to manufacture the invention, and if it appear to be in the general interest of the country or a section of the community or of a trade that such article should be manufactured or any process carried on. The Board of Trade may at any time in their discretion order the voidance or suspension in whole or in part of any patent as they may see fit without special application being made to them. It of course remains to be seen to what extent these provisions are taken advantage of. Contributed by Ridout & Maybee, Patent Agents, Toronto.

CANADIAN TRADE.

STATISTICS of Canadian trade for the first four months of the current fiscal year show a considerable falling off in imports and a slight gain in exports. The total trade for the four months ending with July was $306,908,377, a decrease of $51,196,503, as compared with the same period of last year. Imports totalled $172,041,715, a decrease of $55,627,860. Exports totalled $134,866,664, an increase of $4,431,257.

The chief increases in exports were in manufactures and animal produce. During the four months we exported goods of Canadian manufacture to the value of $21,697,493 and animal produce to the value of $17,283,097; increases respectively as compared with the corresponding period of last year of $2,627,598 and $4,199,863. Exports of agricultural produce for the four months totalled $42,615,242, a decrease of a little over nine millions.

For the twelve months ending July, the total trade of the Dominion was $1,061,365,504, a decrease of nearly $37,000,000. Imports, which totalled $577,936,319, fell off by $114,000,000. Customs revenue for the twelve months totalled $97,094,410, a drop of more than twenty millions.

British Trade Press and The Outlook.—A fully attended meeting of the representatives of the Trade Press of Great Britain was held in London on August 17, at which the following resolutions were unanimously adopted:—That this meeting of editors of trade journals representing most of the industries of the country, after studying the present commercial problems, has come to the following conclusions:—That our commercial prospects were never brighter, and that given patience, confidence, and reasonable sacrifice, there is certain to be a splendid return in the early future. That we strongly urge the public to pay prompt cash for their present requirements; the manufacturer to keep up his production; and the banks to afford all possible support to both wholesaler and retailer. That we request the Controller of Patents to exercise any power he may possess for revoking any British patents owned by hostile countries should they operate against British industry.

Trade Gossip

Wandless Bros., Fredericton, N.B., will install the heating apparatus in the post office building.

The Nobis Engineering Co., Toronto, has been awarded a contract for the heating system of the new Connaught Street school.

The Canada Iron Corporation has been awarded a contract for a quantity of cast iron pipe by the City of Hamilton, Ont.

German Patents.—The Department of Trade and Commerce, Ottawa, announces that German patents issued by Canada may be revoked at an early date.

The A. R. Williams Machinery Co., Toronto, have received an order to supply 3 gap-bed lathes for Valcartier from the Department of Militia.

Hamilton, Ont.—It is announced that the Intercolonial Railway is in the market for new passenger rolling stock, and that the order will probably go to the National Steel Car Co. Basil Magor is president of the company.

The Bromell Patents Co., Glasgow, Scotland, engineers and export merchants announce that they are carrying on business as usual and are prepared to make prompt shipments of all their manufactures. The war conditions have not made any difference to their export trade.

The A. R. Williams Machinery Co. have an interesting display in their window on Front street, in the form of a model battleship, H.M.S. Toronto. The sides of the ship are represented by cotton belting, the decks by circular saws, guns by drills and drill sockets, gun turrets by lathe chucks, masts by drills and holders, funnels by piping, ventilators by W. I. elbows, while dies and knives form the bridge and upper deck.

The Munning-Loeb Co., of Matawan, N.J., manufacturers of electro-platers' and polishers' supplies, announce that they have secured the services of C. G. Backus, who is one of the most highly experienced best equipped and widely known men in plating and polishing lines. Mr. Backus will have charge of their New York office, Room 1373-50 Church street, and will represent them in New York, New Jersey, Pennsylvania and Maryland. His knowledge of details of all plating and polishing processes is entirely at the service of their present or prospective clients whenever same may be required.

War Grist.—J. J. Turner & Sons have received an order for the Canadian contingent of 5,000 kit bags, 50 hospital tents, 100 wagon covers and 1,000 valises. Perhaps no other form of industry is benefited so much by the war as tent makers. The manufacturers of soldiers' uniforms are equally busy. There is also a big demand on shoe manufacturers, and many large makers of harness are very busy making bridles, halters and saddle equipment for the Canadian contingent. It is quite apparent that war conditions are benefiting the above and enabling their staffs to be regularly employed. As the war continues other manufacturers will gradually notice an increased demand for their goods, in lieu of the European commodities which have formerly occupied such a favored position on our market.

Cotton Mills Busy.—The stimulating effect of present conditions upon the Canadian cotton industry has resulted in the resumption of full working time in the ten mills of the Dominion Textile Co. During the eight months prior to the commencement of the war in Europe, the 7,000 employees of this company were working on an average only 70 per cent. of full time. Since the outbreak of hostilities they have been working full time, and if the present demand for Canadian cotton continues, as is likely to be the case, ovetime and double shifts in certain departments will be necessary. The operation at full capacity of the ten mills of the Dominion Textile Co., Limited, will mean the placing in circulation annually of upwards of $10,000,000. Most of this large amount of money will be spent in Canada—in wages, in freight and cartage, in coal, oil and other factory supplies, and in the many other items that enter into the cost of the finished product. As the ten mills of the company are scattered from Kingston to Halifax the benefits accruing from the circulation of this large amount of money will be spread over a wide area.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News.

Engineering

Sault Ste. Marie, Ont.—The British Construction Co. will build the dry dock here, and are in the market for machinery and machine shop equipment.

Sidney, C.B.—The Town Council is considering the purchase of a four-million-gallon capacity turbine pump, with motor, etc. N. Hay, engineer.

Toronto, Ont.—The Wolseley Motor Co. propose to make a large addition to their garage on Avenue Road. Page & Co. are the general contractors.

St. John, N.B.—The Board of Trade has received an inquiry from New Britain (Conn.) with respect to the opportunities here for the establishment of a machine shop.

St. John, N.B.—The Oil Motor and Mfg. Co., of this city, will sell the plant. Tenders to be in by September 19. Particulars obtainable from L. P. Tilley, Princess Street, St. John.

Brockville, Ont—Warwick & Walters, of Montreal, have decided not to establish a plant here, as was originally intended, on account of friction in the Town Council over the proposition.

New Denver, B.C.—The power plant of the New Denver Light & Power Co., is completed and the lights are on again. It is a little over a month since the old plant was totally destroyed by fire.

Medicine Hat, Alta.—The Saskatchewan Bridge & Iron Co., have resumed work on the construction of their plant. It is estimated that the buildings alone will represent an expenditure of $100,000, and expectation is that production will begin in about two months.

Sarnia, Ont.—The Sarnia Metal Products Co. is the latest addition to the industrial enterprises of the Imperial City, and the firm, consisting mostly of Sarnia men, is already having a $20,000 plant constructed on North Front street, near the street railway barns They will manufacture all kinds of corrugated iron, eavestroughs, material for galvanized garages, and other products from light sheet iron.

Fort William, Ont.—The erection of the Fort William plant of the Steel Company of Canada,, on which construction was started last year and not completed owing to the dull season of manufacturing, has been resumed and a large gang of men are hard at work on the completion of the building. J. O. Callahan, general manager of the Steel Company, and B. H. Pratt, of the contracting firm, are at present in the city superintending the work of construction, and have stated the plant will be ready for operation between November 15 and December 1 of the present year.

Electrical

Galt, Ont.—The Canadian Cereal Mill is now run by Hydro-Electrical power. An equipment for 250 h.p. capacity has been installed.

Montreal, Que.—J. C. Wilson, Ltd., are making alterations to their factory.

AUSTRALIAN STREET CARS.

The Department of Trade and Commerce, Ottawa, has available, for the inspection of Canadian manufacturers, specifications and blue prints of the popular types of cars used on the recently established electric tramway systems in Melbourne. Information as to comparative costs is also obtainable upon application to the Commission of Commerce. Should additional particulars be desired, manufacturers are assured of their inquiries receiving the prompt consideration of the above Department.

The contract for the electrical work has been awarded to the Beaver Electric Co., of Montreal, at $30,000.

Winnipeg, Man.—The City Light and Power Department are now supplying the Dominion Government Buildings with electric light. The Winnipeg Electric Railway Co. formerly had the contract.

Kingston, Ont.—Kingston Utilities Commission is considering an offer from J. M. Campbell to supply 500 horsepower of electrical energy from Kingston Mills, at 1¾ cents kilowatt hour.

Hamilton, Ont.—A fire which occurred on Sept. 8, at the plant of the Canadian Tungsten Lamp Co., on Cannon St. east, caused the firemen considerable trouble. The damage is estimated at $1,000, which is covered by insurance.

Windsor, Ont—The Hydro-Electric system was inaugurated by Sir Adam Beck, last Saturday evening, at a ceremony in the local armories. In his address Sir Adam told his hearers that the completion of the transmission line to Windsor marked a new era in long-distance transmission of electricity. The line from Niagara to Windsor is 250 miles in length, one of the longest lines of its kind in the world. The estimated cost of construction of the line was placed at one million dollars, but he said the cost had been much lower.

Municipal

Brantford, Ont.—The council contemplate purchasing a motor-driven combination hose wagon.

Saskatoon, Sask.—The City Council may purchase fire-fighting equipment. T. E. Heath, fire chief.

Toronto, Ont — The Provincial Board of Health has approved of plans for waterworks extensions at Galt, Grimsby and Hamilton.

Ottawa, Ont.—The City Council have adopted the engineer's recommendations for purchasing new equipment for the main pumping station.

Owen Sound, Ont.—The council are considering a proposal to build permanent roads to provide work for unemployed.

Calgary, Alta—A by-law to provide eighty thousand dollars for extension of water works was passed by the ratepayers of Calgary.

Peterborough, Ont.—The city will take over the property of the Peterborough Light and Power Co. A cheque for $100,000 has been paid, in accordance with the expropriation agreement.

Montreal, Que.—Repairs have been completed on the lateral conduit, and the pumps have again been connected, so that the city is again using its regular water supply from the St. Lawrence.

Dartmouth, N.S.—A by-law will be voted on by the ratepayers on October 3, to authorize the issue of debentures to the amount of $90,000 for the erection of school buildings and equipment for same.

Oxy-Acetylene Welding Processes and Their Development*

Staff Article

In the present article attention is drawn to the fact that while for many classes of work autogenous welding has been successful from a general manufacturing and commercial viewpoint, there is every evidence that much still remains to be accomplished before equal success is achieved in the more involved field of mechanical engineering and machine construction.

WITH the application of oxy-acetylene welding to manufacturing, a great many interesting processes have been evolved. The joining together of two stamped plates by its means, making thereby a hollow body has effected a revolution in construction methods. Many articles previously produced at a prohibitive cost can now be competitively manufactured and marketed.

Among the latter are sheaths for swords and knives, walking sticks, umbrellas, radiators for heating plants, hollow steel drums, steel kalamein work, window sashes and all kinds of light sheet work. The same process is applied to pieces which require much greater strength such as bicycle frames, pipes, tubes, automobile frames and accessories and aeroplanes. In the manufacture of multi-cylinder internal combustion engines, the intake and exhaust manifolds are easily made up in this way.

Cutting and Welding Feature.

The combination of the cutting blow-pipe and the welding blow-pipe enables one to obtain cheaply articles formerly very difficult and costly to manufacture at the forge. Thus we can obtain by cutting and welding successively, plates, angle irons, and irons of various profiles, besides details of all manner of forms entering into metal construction. Further than this a very broad field for oxy-acetylene welding is that of repairing. It can be advantageously applied to an almost endless chain of repair work in iron and mild steel. It is often the only process which will allow of the recovery of broken, deformed, or worn-out details. In steel castings, blow holes can be successfully filled with homogeneous metal; cracks in castings can be repaired successfully and made quite as strong as they were originally, while in the sphere of marine engineering a wonderfully interesting field has been opened. When the harder varieties of steel come under the action of the blow-pipe, many difficulties are presented, which up to the present have not been successfully overcome. It will therefore be safer to leave the welding of hard steels alone meantime.

Application to Cast Iron.

Next there comes the broad field of cast iron. The process of oxy-acetylene welding was not applied to cast iron until some years after its application to mild steels and wrought iron. It was then openly declared to be impossible to repair pieces of cast iron by the process. The reason given being that the metal under the action of the blow-pipe became as hard as flint, and in the majority of cases broke upon heating or from contraction when cooling.

As a matter of fact, the welding of cast iron is the easiest of all, or rather, that which gives the best results. The generic name "cast" iron or "castings" of iron is applied to alloys of carbon and iron in which the proportion of carbon is between 2.5 and 6 per cent. Cast iron cannot be forged, and consequently articles in this metal are obtained by casting. In a large majority of cases, the cast iron used for castings contains from 3 to 4 per cent. of carbon. The carbon can be present in very different states, either combined with the iron or dissolved in the metal to which it communicates great hardness. It may also be present in a free state in the form of particles of graphite disseminated in the mass.

In the first case, carbon combined or dissolved makes the metal very hard and difficult to work. This variety of iron is an alloy known as white cast iron. In the second case with most of the carbon in the free state, the metal is soft and easy to work, and is known as grey cast iron. Since the majority of welds in cast iron should be capable of being worked it is indispensable that its constitution should be that of grey iron, of which the great majority of castings are really made.

Grey Iron Welds

The obtaining of welds of grey iron depends solely on the state of the carbon in the metal. It is thus necessary to study the causes which facilitate or prevent its precipitation in the form of graphite. The rapid cooling of the metal in fusion tends to bring about the combination of the carbon with the iron; that is to say, the formation of white iron. On the other hand, slow cooling or reheating tends to bring about the precipitation of the carbon, thus producing a softer iron.

Silicon introduced into cast iron in the form of ferro-silicon takes the place of the carbon. This tends to alloy with the iron and compels it in some way to take the form of graphite, and thus facilitates the formation of grey iron. Manganese, on the other hand, opposes the precipitation of graphite and leads to white iron.

Conditions for Success.

These important effects being known, it is easy to state the general conditions to be observed for the formation of a line of welding in grey iron, that is to say, one easy to file and workable by tools:—

(1)—Slow cooling.

(2)—Introduction of silicon in the welding rod.

(3)—Absence of manganese.

As manganese is often present in cast iron in sufficient quantity to produce the formation of white iron during the welding process, it is much more necessary to observe the above conditions, than the local fusion, and consequent rapid cooling of the metal. The phenomena of oxidation, decarbonization and volatilization of which we will speak, are all conducive to the formation of white iron. According to the proportion of carbon which the cast iron contains, the melting point varies from 1050 degs. to 1200 degs., centigrade, a temperature at least 300 degs. centigrade lower than the melting point of chemically pure iron. The melting point of cast iron with which welders mostly deal with is about 1150 degs. centigrade.

The oxide of iron which is formed melts at about 1350 degs centigrade, and therefore cannot be melted and swept away by the flame as in the case of wrought iron or steel. It forms in consequence an agglomerate in the form of crusts surrounding each part exposed to the air. It is, therefore, necessary to destroy this oxide which prevents the combination of the molten metal and also burns the carbon, thus tending to form white iron. The excessive heat of the welding flame can bring about an alteration of the metal during welding; notably is decarbonization and the volatilization of the silicon.

Expansion and Contraction.

The quantity of heat required to melt cast iron is greater than that required to melt the same weight of aluminum or wrought iron. Cast iron is also a bad conductor of heat, as well as being devoid of elasticity and elongation before rupture. It is, therefore, always neces-

*Second of a series.

sary to foresee that in welding cast iron the phenomena of expansion and contraction can bring about breaks if the shapes of the pieces oppose free play of the metal in heating or cooling, and it is generally necessary to take very special precautions to avoid same.

The difficulties encountered depend almost exclusively on the phenomena just mentioned; the hardness of the metal melted by the action of the blow-pipe making it impossible to work on it with tools, as well as producing cracks and breaks either in the line of welding or elsewhere during the welding or cooling. These difficulties are eliminated to a greater or less extent by using a welding metal of good quality, free from manganese, and yet containing a high percentage of silicon. A further improvement is obtained by the use of a suitable cleaning flux. The effects of expansion and contraction may be overcome by preheating every part of the casting or by any other treatment producing the same results. The lack of elasticity renders cast iron particularly sensitive to the effects of expansion and contraction especially when the heat is localized.

Operators' Troubles.

Certain difficulties in working are sometimes most trying to welders: for example, the fluidity of the metal when melted does not allow of the realization of vertical welds, and it is, therefore, necessary to arrange the line of welding as nearly horizontal as possible which with certain shapes and sizes of pieces is most difficult.

The fluidity of molten cast iron makes it necessary in certain work to surround or hold up the edges to be welded in order to prevent metal from flowing away, and having to weld for a long time over a preheating oven renders the work difficult and tedious, but an operator soon gets used to holding the blowpipe with arms outstretched and in this position making perfect welds. Apart from cracks due to expansion and contraction and the hardness of the line of welding, the welds are susceptible to the following faults:—Lack of penetration, bad joining, interposition of oxide, blow holes, and sinking of the surfaces to be joined.

The edges of the weld should be bevelled if the thickness exceeds ⅛ inch, and welders who attempt to execute welds on 5-16 inch to 7-16 inch thicknesses without bevelling are sure to obtain bad results. In order to secure penetration, they push the molten metal with the rigid white jet, thus bringing about an alteration in the former, as also a partial adhesion. It is always well to introduce into the line of welding as much of the silicous iron as possible, and bevelling facilitates this introduction.

In many pieces of cast iron to be repaired by autogenous welding, in which the repair is a crack and not a break, bevelling can only be done by means of a hand grinder. This should be well done, notably the penetration should be regular and not excessive, so that there are no openings at the bottom of the line of welding. If an extension of the crack is feared by the expansion of the metal during preheating or the execution of the weld, a hole should be drilled a short distance from the end of the crack and in the direction the crack would naturally take, if it extended. The introduction of silicon into the weld through the medium of the welding rod renders still another service. It destroys the oxide of iron, prevents blowholes, and the decarbonization of the metal. Silicon cannot be replaced by any other element, and without it the autogenous welding of cast iron would be difficult to realize. A high percentage of silicon is necessary, because a quantity of it disappears in the course of welding, acting in the capacity of a deoxidiser. Practically it is incorporated in the welding rod specially made for the welding of cast iron, being anywhere from 3.5 to 5 per cent. Welds are then workable if the casting be not cooled too quickly, and if the welder keeps the small white jet of the blowpipe sufficiently well separated from the molten metal. If an excess of solicon be present in the welding rod, the welds produced are too soft. It is, therefore, important that its presence should be uniformly regulated in the welding rod. Manganese should, of course, be absent. Welding rods are manufactured in round sections about 20 inches long, and from ⅛ to ½ inch in diameter.

The Flux Feature.

A flux is necessary to destroy the oxide, and this flux must be less fusible than the metal. The oxide interposes itself in the metal and prevents the perfect joining of the molten bath of metal, while the flux acts as the melter of the oxide of iron and economizes the silicon. The cleaning flux is most appropriate in the form of a powder formed by mixing equal parts of carbonate and bicarbonate of soda, to which is added 10 per cent. to 15 per cent. of borax and 5 per cent. of precipitated silica. This product is supplied commercially at a price so low that welders have no necessity to prepare it for themselves. Other recipes for cleaning powders have been proposed which offer no special advantage, and sometimes have many faults. Certain welders are content to use borax, which as a cleaning flux is insufficient. The powder mentioned above equalizes decarbonization of the cast iron by a corresponding carbonization, a quality which borax does not possess. The silicon of the welding rod, in effect, liberates the carbon contained in the alkaline carbonates, and thus the metal can regain from the flux so constituted the carbon it loses by oxidation. The cleaning flux has also the advantage of protecting the molten metal from excessive oxidation, thanks to the slag which floats on the surface. The flux is used by plunging the extremity of the welding rod into the box or bottle, after the rod has been heated. It is best to avoid thinning the powder into the molten metal whilst executing the weld; the supply from the welding rod being always sufficient.

Preheating.

The execution of welds in cast iron presents no special difficulties when the parts have been properly prepared, preheated to redness when necessary, and using the proper welding rod and cleaning flux. In many cases welds are done with the casting partly or wholly in the preheating oven, the welder protecting himself from the heat by using plates of asbestos or simply plates completely round the parts to be welded. Currents of air must be avoided during welding, as these would bring about rapid cooling and cause breaks or cracks in the piece. For articles which do not require preheating it is advisable to take the chill of the metal, at least around the weld, by playing on it with the blowpipe previous to welding. If local heating be necessary at a different part to counteract the effects of expanding or contracting it is better to do this with a second blowpipe or group of Bunsen burners or benzol lamps.

The total heat of fusion of cast iron being high, it is necessary to use a blowpipe with a greater calorific power than for the same thickness of wrought iron welds. Sometimes when the melting point of the cast iron is notably lower and the conductivity less, a more powerful blowpipe is not used. For a thickness of 3-16 of an inch, for example, a blowpipe of 26.5 cubic feet would be necessary, if the casting were not heated to redness by an oven or flame. In the case of preheating, a blowpipe with a delivery of 17.5 cubic feet of acetylene would prove sufficient. The blowpipe is played on the edges to be welded until melting of the iron just takes place. The regular oscillatory movements are of less importance here on account of the behavior of the metal or melting. However, it is important that the two edges to be joined should melt at the same time.

As soon as the first fusion is obtained, the welding rod powdered with the cleaning flux is applied in the manner indicated in order to avoid oxidation. The melting of the welding rod should take place as much as possible in the molten

bath in the bevel by the plunging in of the rod and then playing the blowpipe all around. This method should always be used for great thicknesses. In the case of thin pieces, the welding rod is melted by sweeping over the molten metal. The point, however, to remember, which applies to all welds, is never to let the metal of the rod fall drop by drop or to hold it too far away from the molten bath. We have already said that to avoid adhesion due to blowing the molten metal along the line of the weld which is not yet at a high enough temperature to receive it, the blowpipe should be held so that the flame strikes the metal almost perpendicularly. A very inclined position of the flame invariably produces trouble and bad results. The white jet of the blowpipe should never be in contact with the metal, and the point should be kept at a distance varying from 3-16 to ¾ of an inch, according to the thickness. This recommendation is very important, as cast iron under the very high temperature of the oxy-acetylene white jet can be degraded by the subsequent oxidation and decarbonization. If in repairing certain articles the molten metal has a tendency to flow away from the line of welding, it can be retained by the aid of plates arranged before welding. The use of clay or refractory earth, as a rule, is conducive to the formation of blowholes, and consequently this practice should be avoided. The plunging of the welding rod into the cleaning flux should not be forgotten as each supply of metal is added, but it is well to remember also that an excess of powder is detrimental. The welding rod containing the element silicon which is indispensable for obtaining a workable cast iron, should be supplied regularly along the line of welding.

Rapid Welding Advisable.

Avoid going over the welds after solidification without adding fresh silicon metal. The danger to be feared is the destruction of the silicon in the line of welding. This tends to produce white iron, or at least the formation of hard grains making it difficult to work. For the same reasons the welds should be rapidly executed without prolonged melting of the metal with the blowpipe.

As has been previously mentioned, the cooling of the cast iron welds should be as slow as possible. It has been found best for articles that have been preheated to replace them in the oven which has been used, and to cover them completely, so as to avoid local cooling. Many articles of cast iron properly welded break or crack in cooling, either in the line of welding or elsewhere, owing to the lack of precautions in view of local contraction. When a coke or charcoal fire has been used for preheating, the piece after being welded should be completely covered with cinders or charcoal, and refractory bricks or sheets of asbestos should be placed on the sides and underneath so as to avoid all draughts of cold air. The article should be left there until it is completely cold.

Sometimes it is necessary to allow twenty-four hours for cooling. For articles which do not require complete preliminary heating it is sufficient after welding to play the blowpipe in the part heated and remove it progressively; next cover with warm cinders, asbestos, or other bad conducting non-fusible material so as to ensure slow cooling. After complete cooling, the welds can be worked with the file, grindstone, chisel, etc., until all the unevenness is removed; thus an absolutely uniform surface can be obtained, on which it is impossible to recognize traces of the breaks or repairs. The oxy-acetylene flame when properly managed does not alter in any way the welded pieces of cast iron. On the contrary, the fusion and rapid solidification gives a fine and compact structure to the added metal, which explains why the metal in the welded part is often much less fragile than the rest of the casting.

Process Saves Wasters.

The process of welding by the oxy-acetylene flame can be employed not only for the repair of all castings broken or deteriorated by use through shocks, vibrations, etc., but also for the putting in order new pieces which have defects, such as blowpipes, pits, flaws, and fractures. This application is not too well known in many foundries as yet, but in the near future there is no doubt but that it will be largely used. It must be recalled that with a weld, if well done, the article treated can be considered equal to new, since the metal added is at least of as good quality as that of the metal in the casting, and when joined to it is perfectly homogeneous. Those foundrymen who hesitate from conscientious motives to apply autogenous welding to the repair of pieces leaving the foundry have only to reproach themselves in obtaining defective welds. Even badly applied, the process is a hundred times preferable from the moral point of view, to the use of cements for hiding blowholes, and sometimes flaws and cracks in articles leaving the foundry.

Foremen charged with the maintenance of works find in autogenous welding a valuable process for the rapid repair of cast iron parts broken in operation of the plant; not only from the economical point of view in not having to purchase a new piece, but also from the fact that the piece is rapidly returned to service.

Application to General Repairs.

Wherever cast iron is used, there lies a field of usefulness for the oxy-acetylene welding process. For example, the repair of flywheels, pulleys, gears, benches, frames of machines, cylinders, stamps, punching machines, autos, motors, steam engines, and vessels of all kinds. In the case of automobile cylinders surrounded by a water jacket, cracks frequently occur due to freezing, heating, shocks, and internal strains, and workshops and garages in the larger towns use mostly autogenous welding for their repair. It is necessary before commencing to weld to preheat the cylinder completely by placing it in a coke or charcoal basket or in an oven until it attains a red heat. The cracks, of course, have to be bevelled and prepared as already explained. After the welding has been completed, it is necessary to cool the casting very slowly. The majority of such cracks appear on the exterior surface of the water jacket or on the flanges or corners, and if the cylinder itself is damaged, the repair is more difficult, because the welding can never be done from the interior. The method is to remove a portion of the water jacket above the crack, and then proceed to weld in the usual manner, and immediately after weld the portion removed from the jacket into position again.

Automobile Repairs.

The success of repairs to automobile parts or similar articles depends above all on the proper preheating of the article and the slow cooling afterward. In the case of cast iron pulleys and flywheels, the execution is more or less easy, depending on the position of the break, the shape and dimension of the casting, and the thickness of metal to be welded. Certain flywheels are easy to repair because the expansion and contraction of the cast iron can take place without tending to produce breaks. Others, again, present difficulties which an inexperienced and thoughtless welder cannot overcome. When the dimensions of the article allow of complete preheating of the whole body and very slow cooling breaks or cracks are not greatly to be feared. On the other hand, however, when the size of the casting makes it impossible to raise to red heat the entire body previous to welding, it is necessary for the welder to exercise thought in overcoming the effects of the expansion and contraction during the execution of the weld, either by working in such a manner as not to have the heated part closed in by parts which are not sufficiently elastic, or by heating certain other parts of the article in order to compensate for expansion and contraction. Seeing the excessive variation in dimensions, shape and thickness of

flywheels, pulleys and gear wheels, it is difficult to give concrete examples or methods of executing welds. The slightest displacement of the break in the rim in its relation to the arm or on the arms themselves often necessitate quite a different treatment in view of the phenomena of expansion and contraction. The welder must exercise his own judgment when undertaking the repair of any broken casting. In the majority of cases large articles cannot be wholly preheated, and in such cases it is necessary to judge in advance how expansion and contraction will act during the execution of the weld and on cooling. Sometimes the breaks are in such places that the repair if not impossible is very laborious, and in many such instances it will pay better to dispose of the casting as scrap metal.

The teeth of cast iron often get broken, thereby making the wheel useless. It is comparatively simple to repair these by autogenous welding. One generally proceeds to replace the broken tooth by adding metal to the base of the tooth and rejecting the piece broken off. A certain amount of skill is necessary in building up the weld without too much flowing on either side, and in keeping the joining of the metal perfect.

Autogenous welding is also employed for adding metal to worn parts of cast iron articles. The operation is the same as for building up teeth of wheels, care being taken that perfect joining of the metal is obtained. If the surface of the article thus prepared has to withstand friction, it requires to be constituted of hard cast iron. To obtain this, it suffices to use a non-silicous welding iron or one that is only slightly silicious. It is best not to reckon on machining such a line of welding after using non-silicous welding rods. The surface may be made even by a wide melting during the operation. Of course, it is understood if the surface of the casting has to be perfectly uniform the process is not applicable.

To sum up, the types of work in cast iron that can be autogenously welded are exceedingly varied, and to execute a number of them calls forth a great deal of thought and no little ingenuity on the part of the welder.

HIGH TEMPERATURES IN CAST IRON CYLINDERS.

IN the construction of internal-combustion engines, the thickness and quality of the material used for cylinders and pistons, and the effects produced by very high temperatures are matters which have to be very seriously considered. It is quite conceivable that a thick cylinder opposed to high temperature as well as to a high pressure inside of it will be actually more stressed than a thinner one. The same reasoning applies to the piston crown and the bottom of the cylinder covers. As was pointed out by J. T. Milton in his paper, the "Present Position of Diesel Engines for Marine Purposes," the metal in these parts is put into a state of compression by the high state of the temperature, the sides being subject to a similar stress due to the pressure. These considerations show the great importance of keeping the thickness of the metal at parts exposed to great heat as thin as possible consistent with their possessing sufficient strength.

It is known that cast iron appreciably changes its form and dimensions through continuous exposure to high temperatures, and so causes troubles similar to those which have occasionally been experienced in large steam engines. It is probably the fear of this action under severe heat conditions which led to the use of cast steel for cylinder covers. Most Diesel engine manufacturers have reverted to the use of cast iron for covers, and some of them give the metal a severe heat treatment before the completion of the machining operations. It is quite possible, however, that cast steel will be again used for these parts.

GRAPHITE LUBRICATION.

THE employment of graphite as a lubricating medium for machinery is a matter which has often been discussed among engineers. The mixing of graphite with oil, a system tried for engine lubrication and other purposes, has not always been attended with such satisfactory results as are to be desired, but there can be no doubt that, properly applied, graphite ranks among the most efficient of all lubricants. Countless experiments have been made to unite the substance with various metals in a molten state, but without success, and another system of application has consisted of graphite plugs inserted in bearing surfaces, but here the cost of drilling the holes for each separate plug and putting each individual one in its place has made the process too expensive for ordinary purposes.

In view of these circumstances it is with interest that we turn to examine a new method of utilizing graphite as a lubricant for white-metal bearings, particulars of which have been communicated to us by the vendors. This is known as the Randall graphite sheet lubricator and consists of a simple device in which solidified graphite cones of a slightly tapered formation are attached by hydraulic pressure to a fine copper-wire screen or fabric which may be cut to the shape and fitted with a minimum of trouble in any white-metal bearing in which it is intended to be used. A piece is cut from the sheet the full length of the bearing, wide enough to reach not quite to the top of the half bearing, and it is important when fitting to so cut the sheet that the plugs or cones have the straight rows running lengthwise, so that the cones are staggered in the path of the rotating journal, and each part of the shaft in the bearing as it revolves will then be in contact with some of the graphite cones.

After cutting, the Randall graphite sheet lubricator can be shaped with the fingers to a half circle a little smaller than the journal, around which, or around a mandril usually employed for the purpose, it is fixed by means of fine copper wire, wound spirally. The small or tapered ends of the cones should always be placed in contact with the journal, so that the wire cloth will be embedded near the bottom of the box. The mandril, with the graphite sheet lubricator attached as described, is placed in the box and the white metal poured in the usual way. The bearing box, mandril and sheet should all be warm so as not to chill the white metal too quickly. The metal will flow and set around the graphite cones, making them a part of the bearing. The result is practically a self-lubricating bearing which requires only a few drops of oil at long intervals.

To finish the bearings, the sides may either be scraped so that the journal will turn freely, or turned in a lathe, which ever is the general practice. In oiling, it is advisable to cut down from 75 to 90 per cent. of the quantity ordinarily used on regular white-metal bearings. Too much oil has a tendency to wash loose particles of graphite out of the bearing.

In considering the first cost of the Randall graphite sheet lubricator, it should be noted that in many cases it displaces sufficient white metal to pay for itself, and is claimed to increase the life of bearings three to four times. Results have shown that this lubricating device enables white-metal bearings to withstand heavy pressures and high speeds without heating. — Shipbuilding and Shipping Record.

C G.E. Service Corps.—A notable contribution to the service of the Empire has been made by the Canadian General Electric Co. By drawing on its technical staff, it has raised a corps of engineers, both electrical and mechanical, for service during the war, and has further undertaken the duty of maintaining the corps for that period.

Galt, Ont.—The Shurley Dietrich Co. are building an addition to their factory 100 x 205 feet.

Training and Educating Employees in a Motor Car Plant

By J. H. Weller *

The accompanying article is worthy the attention and careful study of every employer of labor, setting forth as it does not only the steps which have been taken to train and educate each new generation of employees, but the provision that has also been made, and to which perhaps the greatest importance should be attached, for the administration and training of competent departmental executives.

THE efforts of the Packard Motor Car Co., to train its men to become more efficient, thereby increasing their value to themselves and to the company, may be divided into three lines of activity; namely, the practice given apprentices in the operation of different machines; the instructions given the same apprentice in class-room; and the broad and comprehensive work being done among the factory foremen and their assistants.

The demand for tradesmen in an automobile factory is so diversified that the Packard management has found it expedient to establish a number of different apprentice courses. They now have in their employ boys who have apprenticed themselves to become machinists, tool makers, die sinkers, pattern makers, electricians, body makers, body trimmers, or body painters. These courses are of three years' duration, and the boys receive fourteen cents an hour at the beginning of their course with a semi-annual increase of two cents an hour. At the present time there are about sixty apprentices working in small classes in the different departments throughout the factory, and it is proposed to increase the number by carefully selecting boys who may be recommended.

Requirements to be Met.

Before the boy is allowed to enter upon his apprentice course he must meet certain requirements. He must be at least sixteen years old, and have the equivalent of an eighth grade education. He must pass a physical examination at the shop hospital to make certain that he is sound physically and mentally. After the apprentice has been accepted, he and his parents enter into an agreement with the company that the boy will work diligently to complete his apprentice course. As a guarantee of good faith the boy and his parents deposit $25, and to impress the boy with the seriousness of the contract he and the company's representative sign the indenture papers in the presence of witnesses and a notary public. One of the most important clauses of the contract is the one in which the company agrees to pay a bonus of $100 to those who satisfactorily complete their apprenticeship. Another clause which also urges the boys to perform their duties faithfully is the one which guarantees a two weeks paid vacation to those boys who in the eyes of their instructor have done commendable work.

Apprentice Machinists in the Majority.

Fully one-half of the apprentices are learning the machinists' trade. These boys are divided into classes and placed in charge of competent instructors. The grouping of the apprentices is a matter that has been given most careful study, and so throughout the factory will be found experienced machinists devoting their entire attention to five or six machinists' apprentices.

It has been found desirable to limit to six, the number of boys placed under the instruction of one man, in this way insuring that the apprentices will not suffer from inattention because the foreman is too busy to give them much personal instruction, and that they are less likely to learn bad habits, mechanical and otherwise, from the thoughtless workmen in the shop. The divisions of the machinists' course are well defined, for every six months, these apprentices are sent to a different department under another instructor, or on a different machine in the same department.

The first six months are spent on drill presses, then the apprentice works on lathes for six months, then on milling machines for six months, then at bench and assembly work for six months, and finally he spends six months reviewing the training of two years and one-half. It is the purpose of the Packard Co. to furnish the instructors for the boys, taking other apprenticeships just as soon as the number in the different courses will justify the added expense.

Apprentices as Producers.

There seems to be a difference of opinion about the advisability of making apprentice boys produce work that is to be used in the finished article. It is the policy of the Packard Co. to require their apprentices to be producers from the first day they enter the shop. During the two months trial period, a boy is not trusted with work that demands very much skill. We believe the sense of responsibility which the boy feels when he realizes that he is helping to make a Packard car a credit to the company, puts him on his mettle, and he therefore tries to do the best work he can.

Training Foremen.

There is another group of apprentices in the Packard factory, but composed of older men, many of them being graduates of technical schools. Most of these are men who have shown superior ability, both mechanically and executively; in other words they have been chosen because they are able men. It is the purpose of the Packard management to give these men ample training to qualify them to be foremen, and it is hoped that later on some of the company's executives may be chosen from among the special apprentices.

Since these men are older than the regular apprentices their training is entirely different, and they are thrown more on their resources. At the same time care is taken to make sure that the foremen of the departments in which they are working do not neglect to get in close personal contact with them. To accomplish this end only a few of the special apprentices are allowed in one department. The men in this course are more mature, and in consequence their work is more accurately and conscientiously performed, and they therefore receive a larger renumeration than the younger boys; they being paid twenty-four cents an hour. This rate is constant for the entire course, which lasts one hundred and twenty weeks. The men spend ten weeks in each of the following departments:—Drilling, milling, lathe, screw machine, gear cutting, tool room (bench and machine), assembly, grinding, foundry and tool design.

Apprentice School.

An apprentice school has recently been opened at the Packard factory to aid in the task of teaching apprentices to think. It is aimed to offer to the boys the best possible opportunities to educate themselves, therefore practices in schools of recognized standing throughout the country have been carefully studied. This investigation leads to the belief that five hours a week should be devoted to class-room work, and apprentices are, therefore, required to spend two hours each week in the drawing class, and three hours studying mathematics and mechanics. The work in drawing is done in one two-hour period,

*Supervisor of Labor, Packard Motor Car Co., Detroit, Mich.

while the mathematics and mechanics classes meet for one hour three times a week. Each boy, therefore, spends a portion of four days every week in the class room. This we believe is more satisfactory than it would be to spend a full half-day once a week in the class room, because the boys have less difficulty in mastering the work when only a few points are presented to them at a time.

The Drawing Feature.

The class room work is in charge of a man who has had a number of years of experience in teaching, and who is a graduate of one of our best technical colleges. The class is conducted in a large room on the fourth floor of the office building. The equipment for the work in drawing is designed for a class of twenty-five. Each set consists of a drawing table similar to the kind used in many drafting rooms, a drawing-board, and a complete set of drafting instruments. Besides the standard equipment there are larger boards for the use of the boys doing advanced drawing. In order that the work may be practical and applied as closely as possible to the design of an automobile, the boys make working drawings, or freehand sketches of different parts of the Packard car. An excellent set of machinists' tools is at their disposal, and they are required to take all their own measurements when making a working drawing of a machine part.

Drawing begins with a few plates to teach the apprentices the use of drafting instruments, then they are given a little geometrical drawing. This is followed by the fundamentals of projections; and the major portion of the course is confined to making working drawings. Supplementary to this work is the practice in reading working drawings. A few of the more advanced students study cams and gearing.

Mathematics Course.

The course in mathematics begins with a thorough review of arithmetic. The rest of the work involves the principles of algebra, geometry, and mechanics, and is presented by many applications to shop practice. The boys are also taught to use the trigonometric functions. Encouragement is had in the determination which some of the boys show to master the work, for although the noon hour begins at 11.30 o'clock, many of them are so anxious to solve the problems in mathematics, or grasp the work in drawing that they study until 12.00 o'clock, and often take the work home at night.

To stimulate the desire for good reading, there is a library of some of the best technical books, which is placed at the disposal of the apprentices. Besides this a branch of the city library is opened twice a week, and the boys are urged to broaden themselves by reading good books that are not technical.

Management's Enthusiasm in Work.

All this work of educating young men has been enthusiastically encouraged by the management, but it is considered as secondary to the more important work of educating their departmental executives. Manufacturers are beginning to realize that as their business grows larger and competition grows stronger it is almost impossible to secure a sufficient supply of properly trained and efficient department heads, and the Packard Co. has arrived at the conclusion that the only solution to the problem is to carry on a continual educational campaign among its present foremen and superintendents as well as among a few young men in minor positions, such as assistant foremen and gang bosses who will be available for filling any vacancies which might occur.

Supervisor of Labor Feature.

Further educational work consists of a series of personal talks with the men. This work is carried on by the supervisor of labor, who devotes all of his time to welfare and educational work, and who is endowed with full authority to handle the labor situation and the educational work for the best interests of all concerned. It is his duty to study each man individually. All of his good traits and habits, as well as his failing and weaknesses, are carefully noted. He is invited into a private room where one hour is spent in talking over the subject of departmental supervision.

During the course of these talks reference is made in a very friendly but candid manner to all his failings, and suggestions are made which are helpful to him in correcting them. He is given very explicit instructions as to the proper method of handling his help; how to develop the unskilled into skilled, expert and efficient workmen; how to get them interested in their own future welfare as well as that of the company; how to develop loyalty and make each man in his department feel that he is an important factor in the institution, and that the company has a personal interest in him; how he should meet and instruct new men coming into his department, and make them feel at ease and at home —tell them what he proposes to do for them and what he expects them to do for him.

His attention is called to the folly of simply giving them a job and then leaving them to work out their own salvation, with the little help they may be able to get from the workmen around them. Their attention is called to the importance of keeping efficient men in their departments for long periods of time; that their department positively must be such at all times that their men will respect them; that is, they must be sober, truthful, honest, busy, and above all, punctual; that they must be the first men in the department in the morning and the last out in the evening; that they positively must keep faith with their workmen, and keep every promise made to them; that they cannot abuse them, or swear at them, and when it is necessary to correct them, to call them to one side and privately talk with them with all kindness but with candor; that if they will not respond to that kind of treatment they should dismiss them, but in doing so they should do it privately, give every reason for so doing firmly but briefly. They are told that the company's policy is to retain competent and loyal men, and that sufficient evidence of prejudice or bad temper against loyal workmen will be considered just cause for their dismissal, and it is especially urged upon them as one of their most important duties to train themselves to be affable, honest, straightforward, earnest, and always ready to assist and advise their men, both as to their duties and their personal welfare.

The company believes that as executives sow, so shall they also reap. If they sow disorder and confusion among their men they will reap carelessness and dissatisfaction, but if they sow kindness and interest in their men they should reap honest, loyal and interested workmen. Foremen are told that the efficiency of their departments depends largely upon their ability as foremen to educate workmen and retain them in their department for long periods of time; and that if it were not for the educational work which they are expected to do among the inexperienced workmen, the company would have no further use for their services, except as workmen; for, if all of the men employed were skilled and efficient workmen they would need no mechanical foremen, but simply some clerical help to pass out the jobs to the workmen.

Proper Placing of Employees.

There was a time when foremen were allowed to discharge any man who appeared to be incompetent, or perhaps lazy, but at the present time they are instructed to change these men from job to job in order to try to fit them into a place where their services will be valuable and satisfactory. If, however, they are unable to get them properly placed, they must send them to the office of the supervisor of labor, who will transfer them to another department; or perhaps they are transferred a number of times to different departments until every means for finding a place where their services will be satisfactory has been

exhausted, and they are not discharged until it has been proven to the satisfaction of the supervisor of labor that it is impossible to make men out of them. They are told that discharging men for ignorance does not relieve them of the responsibility or correct the evil, and that every time a workman is discharged it is necessary to hire a new man in his place who may make the same kind of mistakes, and thus the evil goes on indefinitely, or until the management discovers the foreman's weakness and dispenses with his services.

Business Onus of Foremen

The foremen are being taught to conduct their employers' business as they would if their own money were invested. They are given assistance in computing the cost of labor and material brought into and turned out of their department each day, also the cost of spoiled work. Comparisons are made between the expense of proper instruction and efforts that would have made good commercial material instead of scrap, and the cost of labor and material that went into scrap; and this alone has made such an impression that the company has been well paid for all the work they have done in the way of educating their executives. All of these things apply only to the educational work done in the manufacturing departments, and are conducted entirely independent of the educational work done in the sales and advertising departments. After these talks the foremen are closely watched for about sixty days and at the end of that time they are again called into the office, and asked to go over the whole matter again and see what they have accomplished, and they are assured that this work is only the outcome of a desire to make each of them a greater and better executive.

An example of the success and importance of this work is seen in the turn-over of the force which one year ago was about two hundred per cent., while at the present and for several months past, it has been less than fifty per cent. The efficiency of the plant has wonderfully increased, which is shown by the increase in production, an improvement in quality, without any increase in productive force, and a considerable decrease in the non-productive force.

MACHINERY BELTING MARKETS.

BRITISH manufacturers of leather, hair, and cotton belting for machinery will be interested in a memorandum just issued by the Commercial Intelligence Branch of the Board of Trade, 73, Basinghall street, E.C., showing the principal markets to which German and Austrian goods of this class have been exported. Although German exports of these products do not appear to rival those of Great Britain in value, they are in some directions very considerable. To these, however, no less than $493,500 worth of belting from Germany has been sold in a recent year, most of it being of other classes than leather, cotton, or wool.

In other countries the sales are also large. For instance, Germany sold to Russia recently in one year leather belting to the value of $658,500; to Sweden to the value of $114,750; Italy, 115,000. Of German woven hair or cotton belting, Russia took $353,500 worth; France, $70,750, and so on. Roumania is a large purchaser of all classes of German beltings, though latterly the country has developed an industry of this kind itself. France takes a considerable amount of woven belting from Germany. The Russian trade was formerly in the hands of British firms, but has been captured by German efforts. In 1912 Germany's total exports of belting were worth $3,675,000.

ELECTRIC LAMP INDUSTRY BENEFITS BY WAR.

THE tungsten and incandescent lamp industry in Canada will benefit through the industrial conditions created by the war. There have been large importations of tungsten and incandescent lamps from Continental Europe into Canada, and these importations will be greatly curtailed, if not completely cut off, as a result of the war. This will result — indeed has resulted already—in greatly increased demands upon the Canadian manufacturers of these articles.

When the war broke out the plant of the Canadian Tungsten Lamp Co., at Hamilton, was shut down for the summer. Under ordinary conditions operations would not have been resumed until September 15. In view of the probability of an increased demand on account of the war the plant was put in operation on August 15—a month ahead of the usual time. Since operations were recommenced the staff has been employed several nights a week in an effort to keep up with the demand.

Although the present output of the plant is 75 per cent. greater than under normal conditions, it is not sufficient to meet the increased demand. Recently three large orders, which under normal conditions would have kept the plant busy for three weeks, were refused because of the difficulty of filling orders already in hand.

The plant of the Canadian Sunbeam Co., in Toronto, was reopened on July 28 after the usual thirty-day summer shut-down. This plant has been operated ever since at full capacity.

HYDRO-ELECTRIC VS. STEAM.

IN an address before a recent session of the American Society of Heating and Ventilating Engineers, comparing hydro-electric generation of electric current with generation by steam, Reginald Pelham Bolton gave some interesting statistics as to how the advance in generating methods has assisted in conserving the fuel supply. Mr. Bolton took the stand that electric current may be more cheaply generated on the average by steam than by water, and said:—"The amount of fuel used for the production of a kilowatt of energy in modern plants has been undergoing a continuous reduction, as a result of the greater concentration of the production and the resulting use of better proportioned machinery.

The actual conservation which has been effected by the more economic use of fuel in electric power production far exceeds any results that could have been attained by the use of all the water power in present service. In one of our largest cities during the ten years from 1903 to 1912 inclusive, a total of 3,782,000,000 kilowatt hours was generated by the consumption of 6,284,000 tons of coal. In the year 1903 the rate of fuel consumption per kilowatt hour generated was 6.87 pounds. At the end of ten years this rate has been reduced partly by improvements and partly by the larger units operated, as well as by the improved load factor resulting from combining the demands of more consumers, to less than three pounds of coal per kilowatt hour.

The consumption of coal during the ten-year period, if it had been maintained at the rate prevailing in 1903, would have involved the consumption of 13,000,000 tons of coal. There was saved or conserved, by the process of improvement, more than fifty per cent. The use of very large boilers, used at a high rate of output, combined with large generators, has reduced the coal consumption per kilowatt of energy per hour to less than two pounds weight of bituminous coal, as in the Central Station of the Detroit Edison Co.

Our present demand for coal for all purposes is about 575,000,000 tons per annum. The commercial value of the material is mainly composed of the cost of labor and machinery for its extraction and the cost of transportation from its source to its point of usage. Our entire system of railroads and our vast advantages in water transporation are contributory to the economical distribution of coal, and in low cost of output we take the lead in the world with a production of 600 tons per annum per employee, as against 275 tons per annum per employee in the United Kingdom."

PRODUCTION METHODS AND DEVICES

A Department for the Interchange and Distribution of Shop and Office Data and Ideas Evolved from Actual Practical Application and Experience

DRILL JIG FOR ANGULAR HOLES.

By J. P. Sanderson.

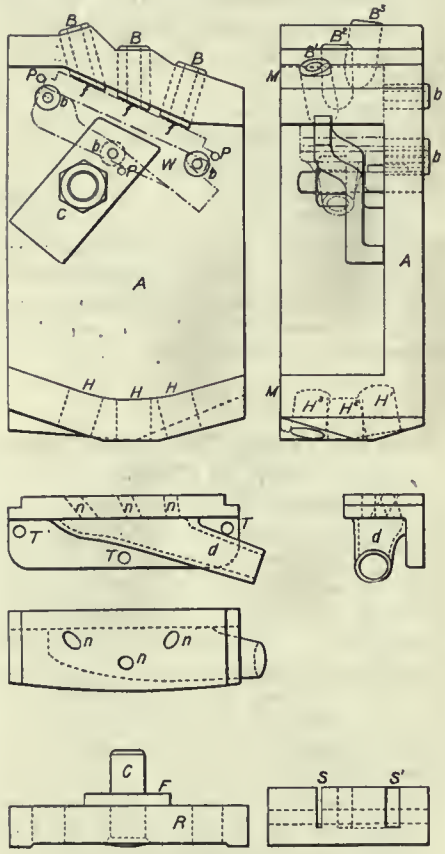
WHERE holes are to be drilled at somewhat acute angles to each other and considerable accuracy is required, the first idea of a jig is usually a very elaborate affair. The plan herein described may not be new to some but one might go the rounds of a large number of shops and not run across it, and the principle involved certainly has simplified a lot of otherwise tedious little jobs.

The work, in this case, consists of the brass nozzle chamber of a very small impulse turbine. It contains three nozzles as shown at (n) Fig. 1. These nozzles are simply drilled holes of suitable size and, as they must be drilled at a common angle to the circumference of a circle, the angles which they bear to each other are somewhat complicated. Besides the three nozzles, there are the three holes T, for the purpose of holding the casting in place on the machine, which are also drilled. The pipe connection (d) is milled off and threaded for a ⅜ in. fitting.

The jig Fig. 2, consists of a U-shaped iron casting of the general form shown. The top leg carries the three drill bushings B for the nozzle holes. The lower ends of these bushings are ground off to form the locating surface (f) for the work which is held tightly against them by the peculiar form of the clamp C. The job is located endwise and at the back by the short pins P. For drilling the nozzle holes, the jig is set up on the plate shown in the left hand part of Fig. 3. This consists of the cast iron base R into which is riveted the shouldered stud C. The part C. of this stud is a sliding fit in the three holes H of the jig which are surrounded with a counterbored surface to rest on the collar part F.

In operation, the plate R is first bolted to the drill press table so that the stud C is directly in line with the drill. A casting, afer having been machined on the face and back on the milling machine, is clamped in position in the jig as shown by the dot and dash outline Fig. 1. The jig is now placed on the plate R so that the stud C slips into one of the holes H and thus holds the jig in position to drill one of the nozzle holes. The hole H^1 is used to drill through the bushing B^1, while H^2 is used for B^2, etc.

The angles which these holes make with the face of the casting are the same, although they appear different in the drawings. This permits the use of a simple expedient to prevent an ordinary twist drill from catching on the slanting surface and being broken. A small steel block is drilled endwise



FIGS. 1-2-3.
DRILL JIG FOR ANGULAR HOLES.

through the center with a hole the same size as the nozzle holes, and is sawn with two slots, S at right angles, and S^1 at the same angle to the central hole as the nozzles are drilled in relation to the face of the nozzle casting. A brass rod is thrust into the hole in the block and, using the slots as guides, small sections are quickly cut off having one angular and one square end. By dropping one of these little pieces into each jig bushing before drilling the nozzle holes, they can be rapidly drilled without danger of breaking the drill, the angular end preventing the strip from turning round. At first sight this appears to be a tedious process but it has been found quite practicable. A couple of strokes with the hack saw does the trick and the time gained in drilling and the permitting of the use of ordinary drills more than makes up for the work of preparing the stubs.

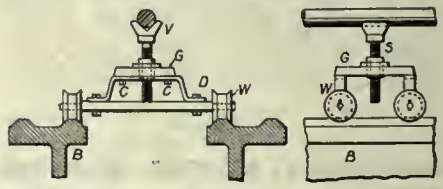
The three holes T are drilled through bushings (bb) in the back of the jig by placing it flat on the table on the faces MM and with the same setting of the work. The job is greatly facilitated by the use of a quick change automatic drill chuck. The pipe connection (d) is machined by placing the jig on edge with one end raised by means of a block which is kept for the purpose. This form of jig, while not the most suitable in cases where an unlimited quantity of work is to be done, has stood the test of a shop in which the castings come in large intermittent batches.

USEFUL SHAFTING CARRIER FIR LATHE.

By J. Davies.

THE accompanying illustration is that of a lathe attachment which recently came under the writer's observation in a Toronto machine shop. It is simple and very inexpensive, and will surely pay for itself in a very short time on a shafting lathe. Its purpose is to facilitate the handling of long shafts in the lathe, particularly when they require to be turned end for end, as is often the case. As nearly all the work is done on the ends of shafting, it is seldom in the way of the carriage, and, if necessary, one man can easily lift it down.

The cut is self-explanatory. The small cast iron wheels W are fitted to the square shaft axles. The square threaded screw S is surmounted by a swivel support for the shaft, as shown, and works in a cast iron nut. This nut is supported by a strong piece of wood, which is in turn fastened to the flat iron frames by the carriage bolts C; these, again, are bolted to the axles. The fixture is, of course, of no use for straightening shafting unless this be done by means of the usual hooks and screw. Its mobility allows it to be easily moved out of the way when the machine is required



USEFUL SHAFTING CARRIER FOR LATHE

for chuck work, and it will be found that it will rarely have to be lifted down.

We have seen a device somewhat similar to this having a split nut, so that when the weight of the shaft is on it the screw is clamped tightly and the ad-

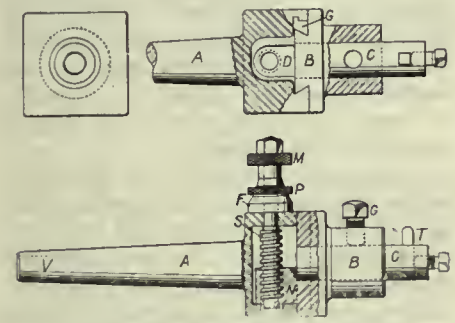
justment for height is not altered by turning the shaft around.—Ed.

ADJUSTABLE BORING TOOL.

By E. W. Tate.

IN the accompanying cut is shown an adjustable boring tool for milling machine work which has the advantage of a wide range of adjustment. The body of the device consists of the shank, which is turned from a square bar of machinery steel of suitable size. The part A is a standard taper to fit the milling machine spindle, the end being drilled and tapped for the draw bolt as shown. The large end is milled out to accommodate the nut D and shaped to form the dove-tailed slide for the head piece B. This sliding part, including the nut D, is made of a single piece of machinery steel and is kept snug by the gib G, which is tapered.

A number of boring bars can be made to accommodate different sizes of holes, the bar C representing the largest. The adjustment is accommplished by means



ADJUSTABLE BORING TOOL

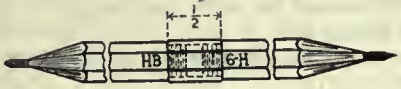
of the square thread screw S through the knurled nut M which is keyed to the screw shank. It can be clamped in any position by the cam nut P. The barrel F is graduated so as to show adjustments to 0.001 in. of boring bar. This fixture has been found particularly useful for boring jigs and other work containing a number of different sized holes as, with the help of one or two easily made bushings, drills as well as boring bars can be readily fastened into the part B.

The arrangement would be much more satisfactory to the safety first movement if hollow set screws were used instead of the old-fashioned ones shown. Also some other devices of a similar nature have done away with the protruding part of the screw shank by arranging this for a hollow set screw wrench as well.—Ed.

A PENCIL JOINT.

By W. H.

WHEN putting in the dimensions lines on a drawing, a hard lead pencil, such as a 6H is used, but when putting in the figures a pencil with soft lead is generally employed. Draftsmen often wish that a pencil could be had that would be adaptable in hard or soft lead, and thus save the bother of constantly picking up and laying down two separate pencils.



A PENCIL JOINT.

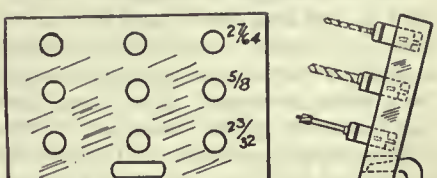
In the accompanying sketch is shown a kink, which serves as near as possible this purpose. A pencil joint made from ¼-in. brass tubing, and about ½ in. long, is tapped in the ends with a ¼-in. tap. A half length each of a hard and soft lead pencil is whittled slightly on the ends, and these are forced into the threads of the tube. The tube is, of course, filled hexagon-shape, and the pencils are replaced as fast as they are used up. The grades of the pencils should be marked on the ends as shown.

HOLDER FOR QUICK-CHANGE COLLETS.

By J. E. Cooley.

AMONG the handiest tools brought out in recent years and those that have greatly reduced the cost of drilling operations are the quick-change drill collets, so-called, because the collets can be inserted and taken out without stopping the spindle. It is often noticed where several collets containing drills, reamers, counter-bores, etc., are in use, that there are no means provided for keeping them together, as they often roll off the drill-press table.

In the accompanying sketch is shown a convenient means for keeping the collets together, and in the order in which the are handled. It consists of a piece of 2-in. plank, having several holes



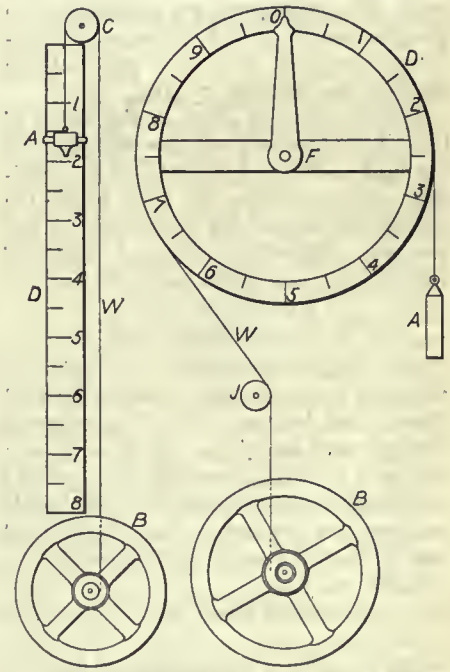
HOLDER FOR QUICK CHANGE COLLETS.

bored in it, as shown for holding the collets. The lower edge of the board is planed on an angle, and it also contains a slot cut, by which it can be fastened down by a clamp to the drill-press table. The front of the board should be painted black, so that the size of the tools in use can be marked near the holes with a piece of chalk, as suggested in the sketch. By having the figures thus plainly written out it will save considerable time hunting for the small stamped figures on a tool each time it is handled. When the tools are removed from the collets, the figures should be erased.

INDICATOR FOR AMOUNT OF VALVE OPENING.

By J. E. Noble.

IN many situations it is often necessary to be able to tell at any time, the number of turns a steam, air or water valve has been opened. A simple device for this purpose, was made up and put into service by the Western Gas Association and has given good results particularly where the valve was required to be used



INDICATOR FOR VALVE OPENING.

as a regulator of the gas flow. In the writer's opinion, it could be used to advantage in a great many shops and power plants.

In the left hand part of the figure, B is the valve wheel and A is a small grooved pulley. One end of the cord W is fastened to the valve spindle while the other passes over the sheave C and is attached to the small pointed lead weight A. A scale D which may be supported in any convenient way or place is graduated so that each division represents one turn of the valve wheel. The position of the weight A in relation to the lines on the scale shows at a glance the setting of the valve.

The right hand part of the figure illustrates the same principle applied to another form of scale. The pointer F is stationary while the scale itself forms the sheave and revolves, the cord being kept tight by the weight A. This form is most useful in cases where the full opening requires a great many turns.

TANK CONTENTS QUERY.

EDITOR Canadian Macsinery.—Will you solve through your journal the following problem:—A horizontal cylindrical tank, 8 ft. in diameter and 23 ft. long, is filled to a depth of 26 inches with oil. How would you determine the quantity of the latter —H. Sorensen, Montreal.

Answer.—Find the area of the end of the body of oil and multiply by its length. The end is in the form of a segment of a circle, and the easiest way to find its area is to find the area of a sector of the same angle and subtract the area of the triangular part.

(1)—To find the chord or the width of the oil surface:—From the diameter of the tank subtract the depth of oil; multiply the remainder by four times the depth, and extract the square root of the product. Diameter = 96 ins.; depth of oil=26 ins., and difference=70 ins.

$$4\times26=104. \text{ and}$$

$$\sqrt{70\times104}=\sqrt{7280}=85.32 \text{ in.}$$

(2)—To find the angle of the sector:—We have a right angled triangle with all three sides known. The hypotenuse is the radius of the circle, which is 48 ins.; the base is $85.32\div2=42.66$ ins., and the other side is 48—26=22 ins. The angle between the hypotenuse and the vertical side is half the angle of the sector.

$$\frac{42.66}{48}=.88875,$$ which is the sine of the required angle. From a table of sines we find this to be the sine of an angle of 62.64 degrees. The whole angle of the sector is then, $62.64\times2=125.28$ degrees.

(3)—To find area of sector:—Area of circle$=48^2\times3.1416=7238.246$ sq. in.

Sector of 360 degrees has an area of 7238.246 sq. in., and sector of 125.28 degrees, therefore, has an area of

$$\frac{7238.246\times125.28}{360}=2518.91 \text{ sq. in.}$$

(4)—To find area of segment:—Area of triangle $=\frac{85.32\times22}{2}=938.52$ sq. in.

Area of segment = area of sector minus area of triangle = 2518.91—938.52=1580.39 sq. in.

(5)—To find volume of oil:—Multiply area of cross-section by length, or

$1580.39\times23\times12$ cubic inches.

1 Imperial gallon=277.274 cubic ins.

$$\text{Number of gallons}=\frac{1580.39\times23\times12}{277.274}$$

$=1573.12$ gallons.

The answer in cubic feet would be

$$\frac{1580.39\times23\times12}{12\times12\times12}=252.42 \text{ cu. ft.}$$—M. L. S.

WANTED A DISTINCTIVE TITLE.

By J. P. S.

A GREAT deal has been said and written of late concerning the requirements of an engineer. In the United States and very largely in this country the man who builds the engine is called a machinist, and he who operates the throttle is spoken of as the engineer. In Great Britain and other parts of the Empire the builder is the engineer and the operator is the engine-driver.

There seems to be little objection in America to a man calling himself whatever he likes, and for this reason most of the professional cognomens have lost a large part of their original significance, and, as a consequence, no longer give the bearer of it the social status that it once did.

A very sensible application of the word is found in marine practice. Here the man in charge of all mechanical appliances of a ship is known as the chief engineer, and his subordinates are known as assistant engineers.

There is nothing to prevent this system being adopted also in power plants. The man in charge of large mercantile buildings or factories who supervises everything in the line of heating, plumbing, sanitation and power has nothing in the way of a calling that will place him in any way above his subordinates.

Gas Association Convention.—About one hundred and fifty delegates from all parts of Canada attended the Seventh Annual Convention of the Canadian Gas Association, composed of the managers and engineers of gas plants in the Dominion, which was held in Ottawa last week. The following officers for the ensuing year were elected: President, H. E. Mann, chief engineer, Montreal Light, Heat & Power Co.; first vice-president, R. A. Wallace, manager Quebec Railway, Light, Heat & Power Co.; second vice-president, J. M. H. Young, manager London Gas Co.; executive committee, A. A. Dion, general superintendent Ottawa Gas Co.; Arthur Hewitt, general manager Consumers' Gas Co., Toronto; Mayor Samuel Carter, Guelph; J. P. King, manager Stratford Gas Co. The next convention will be held in Montreal.

WHAT BE EFFICIENCY?

By J. Ellethorn.

"SAY, boss," said Mike the fireman to the engineer, "what do this thing efficiency in the power plant be that I do be hearing a lot of talk about?" "Well," said the engineer, "efficiency in the power plant means lots of things, and it all depends on who you are and what you want it to mean."

"The agent for Buncums boiler compound will tell you that most fuel is wasted because of scale which no compound will remove like Buncums. The CO_2 recorder man will surely convince you that without his recorder economy is impossible, and the next fellow will try and convince you that the CO_2 outfit is practically useless unless you use his scientifically perfect draft recorder along with it. The combustion expert is positive in asserting that the whole fault lies in improperly constructed furnaces, while the engine builder's agent is just as certain that it is absolutely impossible to secure efficiency unless you use his nearly perfect engine.

"According to what we are told, power plant efficiency is impossible without all of the foregoing, and with the addition of patent furnaces, shaking, dumping, traveling and other kinds of grates, automatic stokers, coal weighers, smoke testers, recording gauges, and about five hundred other devices which may all be good things under proper conditions; but, Mike, the owners of a power plant may have every up-to-date and ahead-of-date article or apparatus manufactured to save steam, water or fuel, to reduce friction and save oil, to work automatically and reduce labor, and still fail to get efficiency or economy."

"Well, well, for heaven's sake, boss, what can a fellow do, or is efficiency an impossibility entirely?"

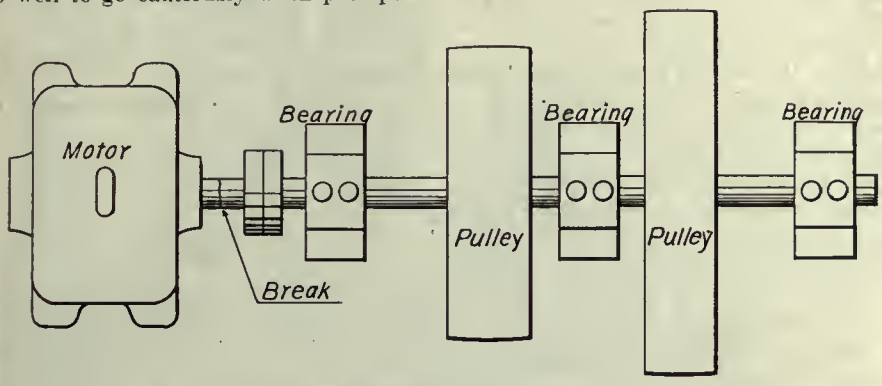
"Listen, Mike, efficiency is quite possible and quite easy. The first requisite is a capable engineer who knows his business and who means business. The second and about as important is an intelligent fireman, or set of firemen, who do not depend on automatic machinery, no matter how perfect, to do their thinking; firemen, to be sure, who know about as much as the engineer, and who get nearly as good wages; firemen, in fact, altogether different from you, Mike, men who know what efficiency means, and who must needs be paid for knowing it. However, as things are, I will

have to use you, and men like you, at the expense of efficiency."

A SHAFT FAILURE WITH A REASON.

By H. Womersley.

IT is often difficult to place the responsibility for the non-success of new machines, and the millwright will often do well to go cautiously when prompted to place the blame for the non-realization of expectations upon the machine or its builders. On the other hand, the maker's reputation will be safeguarded by his assuming the responsibility of putting the machine into successful operation as well as manufacturing it.



MOTOR AND HEAD SHAFT SETTING.

The writer's firm recently furnished an electric alternating current motor to a small manufacturer for the purpose of driving a head shaft. The motor was fitted with ball bearings, and, before leaving the works, was tested out at full load for six hours and at 25 per cent. over-load for one hour. It was set in place by the customer himself, the connection to the head shaft being by means of a coupling, as shown by the illustration.

The machine had scarcely been running two hours when we received a telephone message saying that the rotor shaft had twisted in two. After directing that everything be left in position, the writer hastened to the scene of the trouble and found upon his arrival that the report was substantially correct. The shaft had been twisted off close to the coupling. The head shaft had been supported by two end bearings, as shown, and, upon our advice, an additional bearing was placed near the centre between the pulleys. A new rotor shaft was supplied; the broken shaft was replaced, and the machine has now been in successful operation for about five months.

In this connection a few practical hints on and facts in connection with shafting might be of interest. A revolving shaft having the power applied at one end always twists somewhat throughout its length. In other words, the end to which the power is applied moves slightly in advance of the other end where the work is done. The amount of twist varies directly as the length, directly as the moment of the load, inversely as the rigidity of the material of which the shaft is made, and inversely as the fourth power of the diameter. These laws hold good so long as the material is not stressed beyond the elastic limit.

The transverse strength or resistance to bending is directly proportional to the cube of the diameter and inversely proportional to the distance between supports. The transverse stiffness which determines the deflection is directly proportional to the fourth power of the diameter, and is inversely proportional to the load and to the cube of the distance between supports. The following formulae will be found practical, simple and good for quickly estimating the horse-power that can be transmitted by mild steel shafting:—

For head shafts which are well supported, multiply the cube of the diameter by the revolutions per minute and divide the product by the constant 100. For line shafts well supported use the constant 66 2/3, and for transmission shafts apply the constant 50.

It is an axiom among millwrights that turned shafting, when properly made, is more desirable than cold rolled. The process of manufacturing the latter produces an initial crystallization in the surface and incidentally a soft centre. While it is maintained that the elastic strength and the shock-resisting power of the material is increased, it should be borne in mind that its natural condition is of a soft nature so that the load must be carried mostly by the outer skin or stiffer part of the shaft. When the surface is broken for the purpose of placing keyseats the ensuing spring introduces all the difficulties of shaft straightening. Shafts turned from hot rolled mild steel bars, straightened before being turned, and well finished and polished, will give the strongest combination of stiffness, true running and minimum loss of power.

TREATMENT OF BOILER FEED

THE presence of carbon dioxide in the boiler feed water cannot be considered objectionable as a rule, but where the process of corrosion of the boiler sheets has already started it may accelerate it, says Professor Blacken of Riga. It can, however, be easily removed by caustic soda. Air must be considered as a harmful agent, since the protective action of oxygen in boiler practice has been neither observed nor proved. The air in the presence of chlorides and under certain conditions causes dangerous spot corrosion, and, since it is due to the action of the oxygen of the air mechanically carried into the boiler with the feed water, it is advisable to take care to admit as little as possible.

It is very desirable to admit the feed water either into the steam space or closely below the water level, so as to permit the air to escape into the steam. If there be a large amount of chlorides present in the water, it appears advisable to reject such water entirely, but, if not, it is well to observe the inside of the boiler very carefully, and as soon as signs of corrosion appear, to install zinc plates in metallic connection with the boiler shell, taking care, however, to see that as little as possible of air is allowed to enter, since otherwise the oxygen will in a very short time destroy the zinc. As regards the organic constituents, Reischle, of Munich, discusses particularly the action of various tar, asphalt and graphite paints, and mentions the Brun process, widely used in Switzerland, which consists in the addition to the boiler water of some linseed oil. On the whole, he comes to the following conclusions with respect to the use of means for preventing scale:

They prevent more or less formation of scale, but cannot be considered as a certain method of protection, with the exception, perhaps of the above-mentioned Brun process they produce solution of old scale only occasionally, but usually make it brittle so that it either breaks off itself or can be more easily removed. Sometimes the application may lead to overheating and injurious results to the boiler plates, especially the firebox plates, and finally, they can produce clogging of the water gauge glass and blow-off cocks.—Journal A.S.M.E.

R. A. Ross, consulting engineer of Montreal, has been appointed by the city of Peterborough as their representative on the board of arbitration appointed to settle the question with regard to the taking over of the plant of the Peterborough Light & Power Co. by the city.

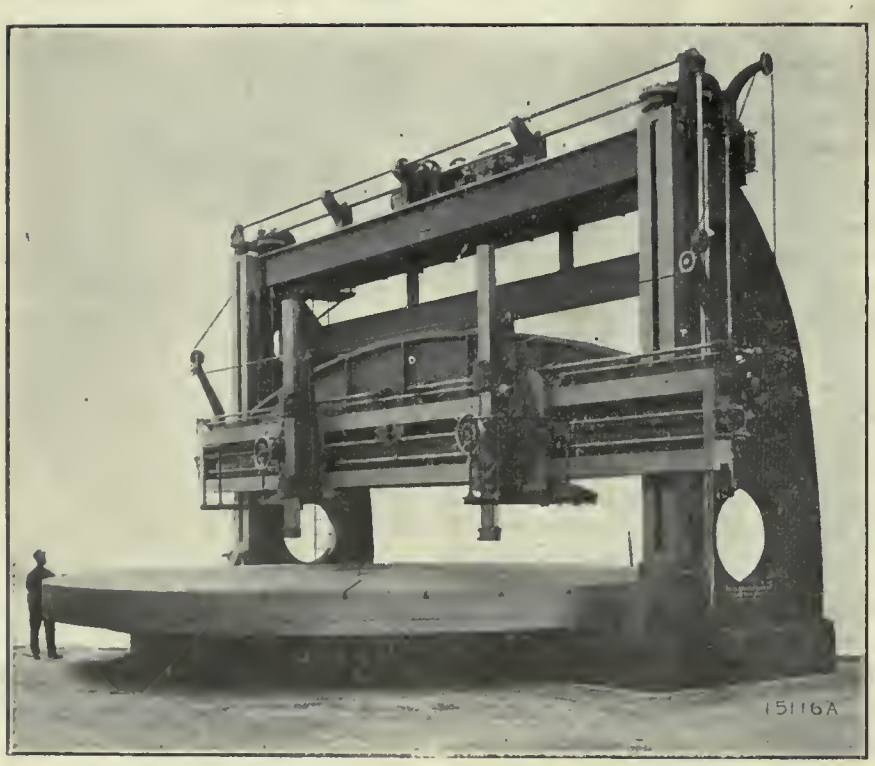
PROGRESS IN NEW EQUIPMENT

A Record of New and Improved Machinery and Accessories for the Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

LARGEST BORING MILL YET BUILT IN AMERICA.

A has recently been completed the T the Brooklyn Navy Yard, there installation of the largest boring mill yet built on this continent. This mill was made by the Niles-Bement-Pond Co. at their Niles Works, Hamilton, Ohio. It swings 36 ft. in diameter and has 12 ft. under tools. The great swing of this machine is required for finishing the tracks of the immense turrets carrying the 14 and 16-inch guns of the new battleships. The mill will also be used for boring cylinders and machining castings of the giant steam turbines for war vessels.

The significant feature about the size



LARGEST BORING MILL YET BUILT ON THIS CONTINENT.

of this mill is that it is not of the so-called extension type, but it is a regular cross-rail machine with an actual swing of 36 ft. 2 inches, with the housings in a fixed position. An idea of the size and massiveness can be gained from the fact that the total net weight including motors, is 665,000 lbs., or over 330 tons.

The table is designed to carry a weight of over 200,000 lbs., and its extreme size, 34 ft. diameter, made it necessary to cast it in three parts, the three sections weighing 225,000 lbs. The table is supported on conical rollers running in a circular track 24 ft. in diameter, sunk in the bed. Rollers are of high carbon steel and fitted to circular guide frames to insure alignment of the rollers. In addition, the table rests in an annular adjustable bearing ring surrounding the central spindle. The bearing ring is adjusted vertically by steel screws, while the spindle is centered in the bed by an adjustable conical bush. Table tracks and spindle have forced lubrication from a pump operated from the main driving motor. The table is fitted with a spur gear 28 ft. in diameter which is a semi-steel casting, with teeth cut from the solid. It is driven by means of two forged steel pinions, placed on opposite sides of the mill.

The main part of the bed is made in two sections, and there are two bed extensions attached to the main bed. The whole bed weighed 69,000 lbs. in the rough, and the other section 48,600 lbs. The table tracks are rigidly supported by the vertical webs of bed.

The housings are box castings of massive construction, connected at the top by a heavy cross brace. Rigidity is further increased by a steel girder connecting the housings. Each housing weighed in the rough 32,000 lbs.

The cross-rail is about 46 ft. long and weighed 85,000 lbs. in the rough. It is a box casting. Bolted to the top of the cross-rail is a massive camber beam, its function being to stiffen the cross-rail and take up the sag due to the great weight of the cross-rail and the heads. The combined depth of the cross-rail and the camber is 8 ft. The rail is raised and lowered by means of a 30 h.p. motor located on the top cross brace and connected to four elevating screws of large diameter working in bronze nuts. The cross-rail is fitted with two heads for boring and turning. The heads are right and left, so arranged that either can be moved to the centre. They are provided with graduating swivels, with worm gearing for setting them over to any angle on either side of the vertical of 30 degrees or less.

The heads and bars are provided with rapid power traverse, as well as hand movement for close adjustment. The rapid traverse is operated by a 10 h.p. motor located on the top brace. The control of these operations and also the engaging and disengaging of feeds is from a platform attached to each head, upon which the operator stands. The operating levers are interlocking so that the rapid traverse cannot be engaged for one head unless it is disengaged from the other, making it impossible for the operator on one head to accidentally move the opposite one.

Eight reversible power feeds are provided for the bars and are operative in a vertical or angular direction. The feeds for each head are entirely independent and positive. Means are provided by friction clutches to prevent the breakage of feed gearing, should either bar or saddle encounter obstruction.

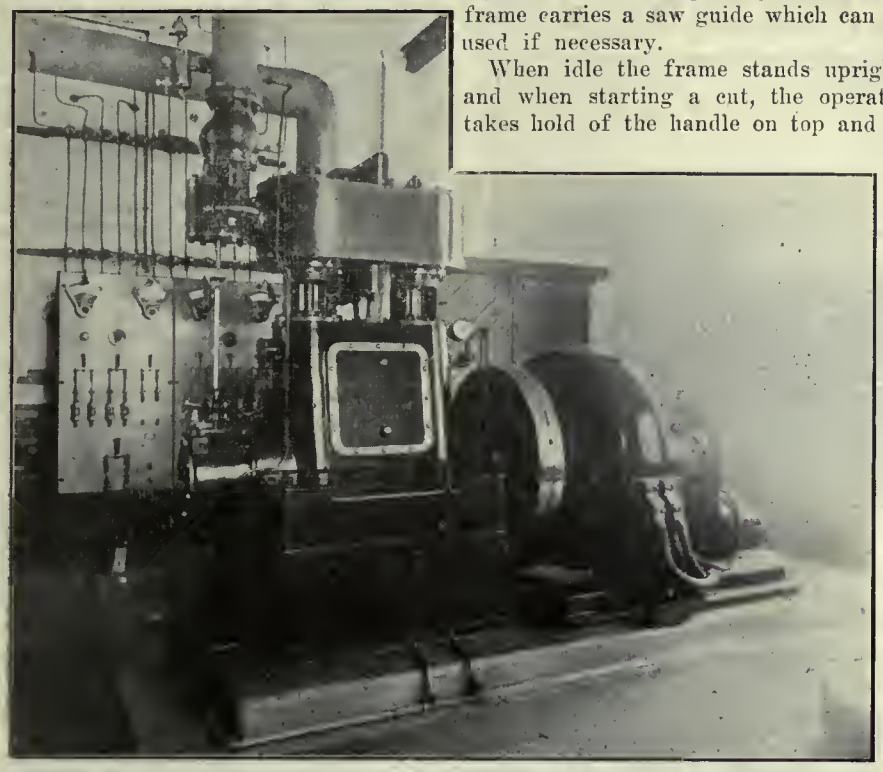
The main drive is by a 75 h.p. motor, and speeds are provided for boring, turning and facing operations.

ENGINE AND GENERATOR INSTALLATION.

THE Imperial Oil Co., of Sarnia, Ont., recently added to their electrical equipment, the following power generation unit. It consists of a direct current generator, 125 k.w., 450 r.p.m., 125 volts, built by the Canadian General Electric Co., Toronto, and driven by a Goldie & McCulloch, Galt, Ont., vertical twin cylinder, non-condensing, forced lubrication engine, taking steam of 80 lbs. pressure at throttle valve and exhausting against 8 pounds back pressure.

This twin engine has been specially

developed to meet cases where considerable power is required, with only a low steam pressure available at the throttle valve, or where the engine is exhausting against very considerable back pressure. Features of this engine are the small floor space required for the horse power developed and the great reduction in cost of engine and generator due to the high speed at which they can be operated.



ENGINE AND GENE RATOR INSTALLATION.

The switchboard, also built by the Canadian General Electric Co., consists of Blue Vermont marble panels, arranged so that each panel contains all the necessary equipment for control, consisting of one d.c. generator, and 3 feeder circuits. For each generator there is provided an ammeter and voltmeter, rheostat, main and equalizer switches with fuses, and for each generator circuit one double pole, single throw knife switch with enclosed fuses.

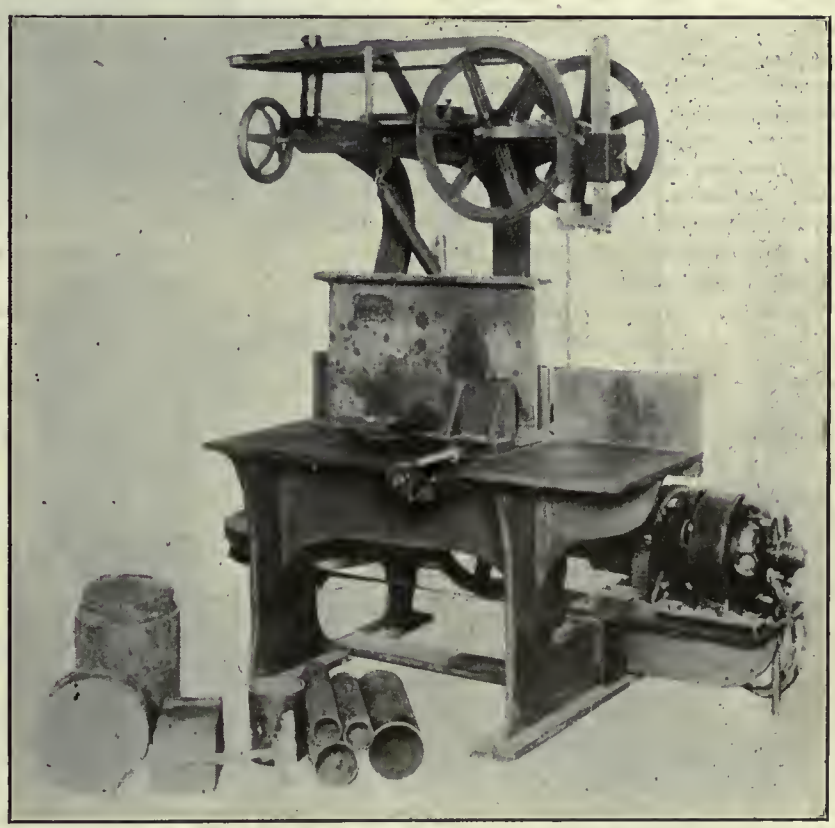
MOTOR-DRIVEN METAL BAND SAW.

THE metal band saw here described and illustrated is a product of the H. C. Williamson Co., Lake Street, Chicago, Ill. Its construction is such that any length of stock can be cut off, as the blade is carried sixteen inches to the rear by the arrangement of the wheels. The swinging frame is rigid in construction, while the bed is substantial and the table has holes drilled and tapped for strapping on special work. Swivel back and vise are furnished on table for cutting at any angle. The drive shaft carries a 24-tooth pinion, meshing into a 96-tooth gear. There is a hand wheel to tighten saw with ample adjustment. The frame carries a saw guide which can be used if necessary.

When idle the frame stands upright, and when starting a cut, the operator takes hold of the handle on top and in front of frame, placing saw to the work; it then feeds by gravity, without further attention. An automatic stop shuts off the power on the belt-driven machine when through cutting, while the spring retards the fall, giving an even pressure all the way down. The pulleys are flanged to prevent the blade running off. By folding the band saw blade, it can readily be seen that the blade runs in its own natural position, a very desirable feature. The saw blade should, of course, be kept tight.

Among the many interesting features of this machine there may be noted the following:—Being continuous cutting, the saw runs faster than on a reciprocating machine; it will cut off any size of I beam up to 12 inches with a perfection almost equal to that of a milling machine; it cuts off tool steel discs, square and eliminates much of the waste due to running allowance; the vise and back can be removed, giving a plain table 14 ins. x 36 ins.; no expensive help is required for its operation, and should a blade break it can be brazed and used again.

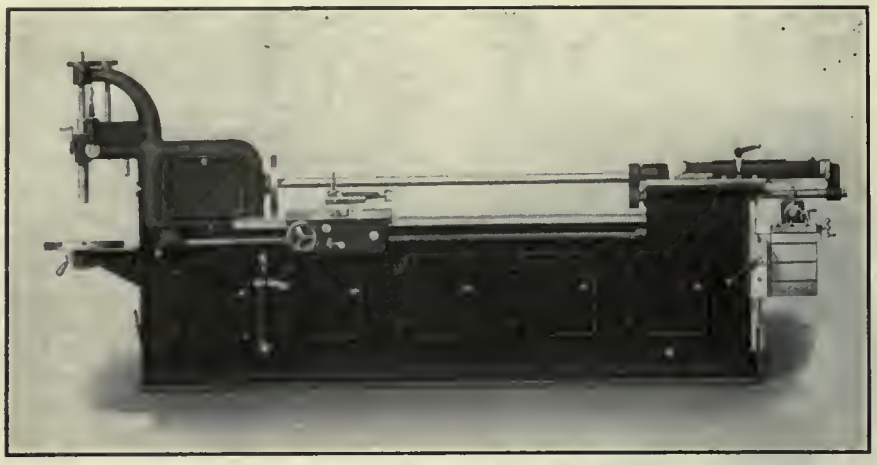
The table is 20 inches high, being, therefore, convenient for handling heavy pieces. The floor space occupied is 36 ins. x 50 ins.; the approximate weight, 900 lbs., and when motor-driven a ½ h.p. motor running 1,200 r.p.m. is employed. For cutting tool steel the pulley speeds are 130 r.p.m., and for mild steel they are 175 r.p.m. The machine will cut off from ⅛ in. to 10 ins. round of any length, and is also highly suitable for pipe and tube cutting.



MOTOR-DRIVEN METAL BAND SAW.

A UNIVERSAL MACHINE TOOL.

SPECIAL construction work and repair bills are costly enough, but it is the lost time required to deliver the material to a machine shop, to explain what is wanted, to await the convenience of one who at best cannot realize what the delay is costing you, that are factors of vital concern to the manager and superintendent of any industry which does not now operate an auxiliary machine shop. Many industries evade this auxiliary machine shop installation for several very logical reasons, viz.: The room required, installation details and expense, the necessity of employing machinists, and other reasons.



DRILL, LATHE AND MILLING MACHINE COMBINATION.

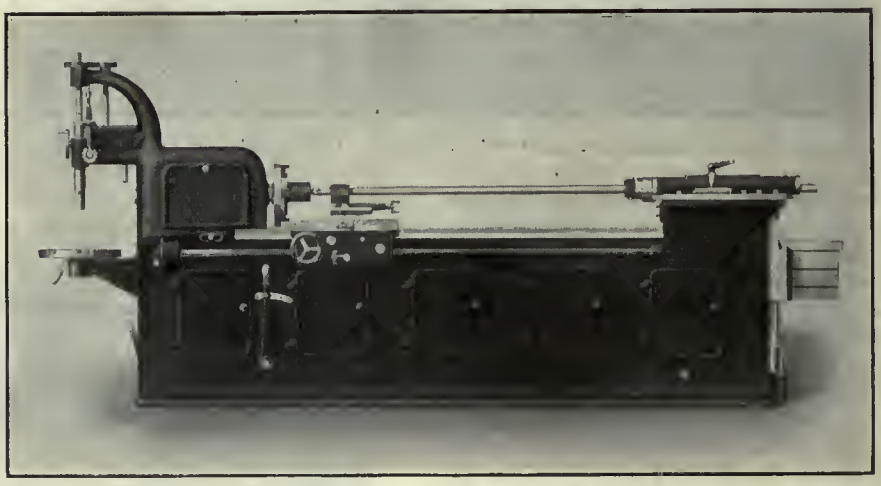
To reduce these objections to a minimum and to offer the benefits derived by quick repairs low costs this combined machine shop tool—a lathe, drill press, milling machine, shaper and keyseater—has been put on the market by the Canadian Linderman Co., Woodstock, Ont. With a floor space of 11 ft. x 22 in., this combination machine can be placed in any convenient spot, tool room, engine room, or at any other point most suitable. Driven by motor, it can be operated at any time when the factory is not in operation. It is also built, when ordered, to drive from line shaft.

In addition to being used for repairs, jigs or special tools, it can also be used for experimental work; to build special machines; in garages to make immediate repairs; or on board ship in cases of emergency, or to prevent delay in port. Occupying but twenty square feet, it can be placed in any convenient spot. Three men can work at once if necessary, each having separate control over his own machine.

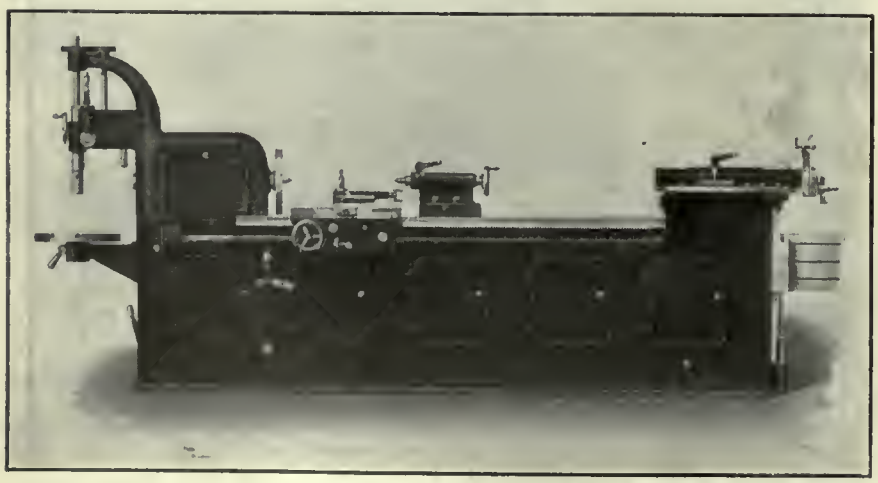
The main frame is 11 ft. long x 22 in. wide, resting its entire length and width on the floor, thereby giving an even strain and having approximately only 25 lbs. pressure to the square foot. The rigidity of this construction assures accuracy for each tool. The following particulars of each purpose equipment will give some idea of the production scope of the combination machine:—

Engine Lathe — Distance between centres, 44 inches; gap bed for 24 in. diameter swings over vees, 16 ins.; swing over carriage, 10 ins.; all geared headstock with enclosed gears; eight speeds, compound rest, set over tailstock; length of carriage, 27⅛ ins.; cuts any standard thread from 3 to 24, including 11½.

Drill Press—Drills holes from ⅛ to 1½ ins. diameter; drills to 20¼ inch centre; spindle feed, 8 ins.; maximum distance, spindle to floor, 40 ins.; and spindle to table, 22 ins.



DRILL LATHE AND KEYSEATER COMBINATION.



DRILL, LATHE AND SHAPER COMBINATION.

Milling Machine—Geared head drive from lathe through 2-inch transmission bar; back geared, two to one; power and vertical feeds, 14 ins.; lateral feed, 4 ins.; distance from table to spindle from 3 ins. to 14 ins. A dividing head can also be furnished, as well as a ram fixture for outboard support.

Shaper—Size of machine, 14 ins.; extreme length of stroke, 14 ins.; cross motion of table, 19 ins.; vertical adjustment, 14 ins.; distance between table and ram, 16 ins.; feed of tool block, 4 ins.; length of top of table, 15 ins.; width of top of table, 11 ins.; keyseating capacity, 2½ ins.; tilting table, zero to 90 degrees.

Key-Seater—Key-seating capacity, 8 ins.; stroke, 14 ins.; work held in lathe chuck; key-seating bar guide held in tool post; shaper head in rear of ram gives taper to key seat; feed for keyseating tool through cross slide.

A few operation facts relative to this machine are that it will turn, bore, face

and key seat pulleys or gears up to 24 inches diameter at one chucking; thread nuts and bolts of practically any diameter and thread; cut off and thread pipe and fittings up to 8 inches diameter; cut interior keyways up to 5/8 inch wide by 13 inches long, and with grinding attachment, cylindrical grinding, both interior and exterior, can be done. It will broach irregular-shaped holes, profile an interior or exterior cam, mill a slot lengthwise and shape a slot crosswise on the same chucking, key seat shafting up to 4 inches diameter, drill and pin the teeth in a broken gear and re-cut the teeth accurately, and cut a spur, mitre or bevel gear with dividing head attachment.

CHAIN SOCKET FOR ELECTRIC LAMPS.

THE Monarch Electric Co., of St. Lambert, P.Q., have recently put on the market a new chain socket for electric lamps. The construction of this new socket is very substantial and simple. It consists of a base, pull chain, switch mechanism, lamp holder, brass shell, cap and necessary insulating fibre.

The base consists of two pieces of unglazed porcelain, and between these pieces are located the various links which constitute the switch mechanism. The supports for the top piece of porcelain and the current carrying parts are mounted in grooves on the lower porcelain to prevent turning. There are three brass supports carrying the top piece of porcelain. These struts are about 0.05 inches in thickness. The first is a support for the chain bell, while the other two act as terminals. These latter are provided with upturned lugs for holding the wires under the binding screw heads. The screws used are No. 5, of 40 threads per inch. The spacing points of opposite polarity are everywhere spaced at 3-64 of an inch apart or a greater distance.

The lamp holder is of the standard Edison screw shell design, and is held to the base by two screws. One of these screws is the current carrying conductor to the shell. The other screw is of opposite polarity and extends through the central portion of the base and through a large hole in the holder. Washers of mica capped by a smaller brass washer communicate pressure to the internal flange of the holder. Thus by means of the second screw and a direct pressure, the holder is rigidly attached to the porcelain base. The sealing is done by wax which will not melt at 200° F., and is made in compliance with rule No. 72 of the National Electric Code.

The cap is brass and of the usual fixture type. The method of fastening it to the shell is somewhat unique. On the body of the shell about 3-32 of an inch from the top are two groups of four outpressed lugs. These are pressed out from the body of the shell and the groups are diametrically opposite each other. The cap is provided with an interior brass ring punched with a series of rectangular holes to engage with the outstanding lugs. The holes are so

CHAIN SOCKET FOR ELECTRIC LAMPS.

punched that the cap will fit on the body when simply pushed over it. It is therefore unnecessary to twist the cap until the holes and lugs register against each other. The shell and cap are both lined with heavy fibre approximately 0.035 of an inch thick. The chain is of the universal design, the inner end lying in a channel of white horn fibre.

The switch mechanism is of the single pole, single break type. It is very simply constructed. A flat rectangular piece of porcelain is mounted on a central pin, and one side of this porcelain is faced with a copper conductor connecting with the central pin which is in turn connected with the central terminal screw. This rectangular porcelain is made to go

CHAIN SOCKET FOR ELECTRIC LAMPS.

through one-half a revolution each time the chain is pulled. The motion is accomplished by means of two springs and a cam. Thus every other time the chain is pulled, the flat non-conducting side of the rectangular porcelain piece is pressed against the terminal and the current is broken. Further, every other time the chain is pulled, the copper faced side of the porcelain is in contact with the terminal and the circuit is complete.

This socket has been tested under a voltage of 242 with a current on one ampere. After twenty-nine thousand cycles were completed, the socket was taken apart and examined, and found to be in excellent condition.

LAKE SUPERIOR STEEL OUTLOOK

IN his report to the shareholders of the Lake Superior Corporation, J. Frater Taylor, the president, reviews the position of the subsidiary companies, which include Algoma Steel, Algoma Central and Hudson Bay Railway, Algoma Western Railway, International Transit Co., Trans St. Mary Traction Co., Togona Water & Light Co. Regarding Algoma Steel, which is the foremost of the enterprises, Mr. Taylor says:—

"Pig iron production has been well maintained, and the rail mill output has exceeded that of any previous year. On account of the smaller demand for Merchant Mill material, the output from the Merchant Mills is less than for the previous year.

"The company's mines in the Michipicoten District are operating to full capacity, and are producing ore of a satisfactory grade, part of which is being used in the blast furnaces, the remainder being sold in the open market. As anticipated in the last report Magpie Mine commenced shipments of ore in the month of May."

With respect to the general outlook, Mr. Taylor says:—"Whilst the volume of business has been fully maintained, and the earnings compared favorably with those of the previous year, the outlook is somewhat uncertain. The demand for steel products has fallen off and money stringency, owing to the European situation, is operating as an adverse factor. In view of the continuing necessity for outlay upon the older plants and properties of the Steel Company and its consequent inability to provide the Lake Superior Corporation with sufficient revenue, your directors regret that this year they will be unable to pay any interest on the income bonds.

"Throughout the year, capital expenditure has been curtailed as far as possible. Unforeseen expenditure occurred through the collapse of part of the Ore Dock at the Sault and the consequent loss of the Ore Bridge last winter. The existing battery of open hearth furnaces is being added to by the construction of two additional furnaces, bringing the capacity of this plant up to 20,000 tons of steel ingots per month."

D. Meadows, of St. Thomas, Ont., has been appointed treasurer of the Travelling Engineers' Association.

Series of Practical Questions and Answers for Mechanics

Every care is being taken to include only pertinent, practical questions, and give same direct reliable answers. Catch questions will be avoided. Arithmetic, consisting of simple addition, subtraction, multiplication and division of decimals, will be found a most useful companion study, and should not be overlooked.

Question.—Making no allowances for losses, in what time will a standpipe be filled by a duplex pump having 30-in. plungers, 34-in. stroke, and making 20 strokes per minute? The standpipe is 125 feet high. and contains 198,804 gallons.

Answer.—One Imperial gallon contains 277,274 cu. in. The volume of the standpipe is 198,804×277.274 cu. in.

Amount of water pumped at each stroke is $15^2 \times 3.1416 \times 34 \times 2$. Amount pumped per minute

$$= 15 \times 15 \times 3.1416 \times 34 \times 2 \times 20$$

Time required to fill the tank is

$$\frac{198804 \times 277{,}274}{15 \times 15 \times 3.1416 \times 34 \times 2 \times 20} = 57.31 \text{ mins.}$$

* * *

Question.—How many yards of concrete would be required for an engine foundation, the sides of which slope up like a frustrum of a pyramid? The base is 31×12 ft., the top is 26×9 ft., and the height is 11 ft.

Answer.—To find the volume of a frustrum of a pyramid or cone, add together the areas of both bases and the square root of their product. Multiply the sum by one-third the height.

Area of base=31×12=372 sq. ft.

Area of top surface=26×9=234 sq. ft.

$$\sqrt{(372 \times 234)} = 295$$

$$\text{Volume} = \frac{(372 + 234 + 295) \times 11}{3}$$

$$= 3303.66 \text{ cu. ft.}$$

$$= \frac{3303.66}{27} = 122.358 \text{ yards.}$$

* * *

Question.—Approximately how many tons of pea coal would be contained in a conical pile 24 feet high?

Answer—The angle of repose or the angle at which the coal would stand is about 48 deg. The radius of the base would be found by simple trigonometry.

$$\text{The tangent of 48 deg.} = \frac{\text{Radius of base}}{\text{Height}};$$

therefore,

Radius of base = Height × tangent of 48 deg. = 24×1.1106 = 26.654 ft.

Volume of pile = Area of base × 1/3 height.

$$= \frac{26.654^2 \times .7854 \times 24}{3} = 4463.18 \text{ cu. ft.}$$

One ton = 32.77 cu. ft. No. of tons then

$$= \frac{4463.18}{32.77} = 136.2 \text{ tons.}$$

Question.—In a hydraulic plunger elevator system with lift 165 feet, and operated by electric-driven centrifugal pumps, will the power consumption for a given travel be greater when the system is operated at 175 than at 160 lb. pressure? Assuming that the consumption is greater in the former case, as seems correct, what becomes of the extra power required when operating at the higher pressure, the travel and ultimate work accomplished in either case being the same?

Answer.—Hydraulic elevators operated by electrically-driven centrifugal or triplex pumps require the use of a storage tank in which the air is the cushioning medium. If the pressure of the system were 160 lb., the pressure of the compressed air in the receiving tank would be 160 lb. Should this be compressed at 175 lb. instead of 160 lb., more heat would be generated in the compression and therefore the radiation of heat would be greater than at 160 lb. pressure. Assuming the efficiency of the pumps at the two pressures to be the same, the only difference in the current consumption would be the extra heat unit lost in compressing to a higher pressure. However, other losses such as efficiency of apparatus, friction, etc., might affect the current consumption, the difference in current consumption depending on the physical design of the apparatus in question.

* * *

Question.—We are making castings that require a minimum tensile strength of 24,000 lbs per square inch, and would like to know of a mixture of ordinary No. 2 foundry iron, cast scrap, and steel scrap that would be suitable. We have two grades of No. 2 iron, one containing 2.50 per cent. silicon and the other 2.25 per cent. silicon.

Answer.—You should have no trouble in getting the strength you require with these irons by adding from 10 to 20 per cent. steel scrap. The addition of 2 oz. of pure aluminum in the ladle, to every 100 lbs. of metal will help you get a good sound casting. Put the aluminum in the ladle before the iron is tapped in.

* * *

Question.—We are making rolls that must stand a pressure of 80 lbs. steam and a hydrostatic pressure of 200 lbs. We cannot get our iron sufficiently close grained for this pressure. The rolls are cast on their side.

Answer.—Pour your moulds on end and gate from bottom if possible. Put heavy riser on top so as to carry out all impurities. You might also change your mixture until you have the grain close enough for your purpose.

* * *

Question.—Please give a formula for brass to make plumbers' goods. We would like a good cheap mixture.

Answer.—The following is a mixture that has given good results on high-pressure work: Sheet brass clippings 71½ lbs., copper wire 25 lbs.; lead 2 lbs., tin 1 lb., prosphor-copper (15 per cent.) 8 oz. Charge the copper wire first and when it begins to sink throw in a small shovelful of charcoal. When copper is melted add phosphor-copper. The clippings are next charged, and a ring should be placed on the crucible to increase its height so that a larger quantity can be packed in each time. When the clippings are all fed into the molten copper and are melted, add the tin, and lastly the lead. The metal will be ready to pour when it ceases to boil or to impart vibrations to the skimmer. When pouring the moulds, the metal should be rushed in quickly and with decision, otherwise the castings will be smoky.

* * *

Question.—We are having trouble with pin-holes in our bronze mixture and would be pleased if you could tell us how to overcome this difficulty. We have been using the following mixture: Copper 90 pounds, phosphorus copper 5 lbs., and lead 5 lbs.

Answer.—This is a peculiar alloy and we could advise you more definitely if we knew what your castings were used for, but we would suggest you change your mixture to the following: Copper 90 lbs., phosphorus copper 3 lbs., tin 2 lbs. and lead 5 lbs. We advise this change, as it is difficult to make an alloy of copper and lead alone, and in case an anti-acid alloy is desired, this mixture is equally as good as an all-lead mixture, and is more easily cast. The pin holes, however, are caused by the meal being burned while in the furnace and we advise the use of charcoal as a covering, and greater care in the melting. Use a small handful of salt as a flux on the first metal charged in crucible, and feed your cold metal into your molten mixture slowly.

MADE IN CANADA.

WE have noted a commendable and vigorous campaign on the part of the various Canadian Manufacturers' Associations to induce the general public to buy where possible, home-made goods in preference to imported articles. It is true that many millions of dollars go out of the country that, if retained, would largely find their way to the pockets of Canadian workmen.

Like all other questions, this one has two sides, both of which must needs be considered. The wage-earner, or the man receiving a small salary is making a considerable sacrifice in deliberately buying a more expensive article simply because it is made in Canada and, even if he be certain that the extra money paid will come back to another Canadian workman, he has no assurance that the smallest part of it will go to increase his own income. The public to whom the appeal is made should be taught how it is that, with the help of the tariff and if anything lower wages to pay, home products cannot be made more attractive to them.

We feel sure that the public spirit of the great majority of Canadian citizens is such that they will favor home-made goods if the quality and cost compare at all reasonably with others, and this is where manufacturers themselves should take up the responsibility and add to their present educative efforts that of not only personal example but an earnest endeavor to produce goods that will require no patriotic exhortation to take them to the homes of the Canadian people.

OUR OVER-DONE WAR FEVER.

THE past season in its every feature has been a disastrous one so far as Canadian shipping and railroad transportation is concerned. To the European war, of course, must be attributed the disorganized ocean traffic to our shores, the curtailment and premature closing of the passenger and tourist service on our inland waters, and to some extent also the decreased movement of freight on the latter and on our railroads. The advent of the war, coming as it did when the wave of commercial depression had not fully spent itself, gave a renewed impetus and an added strength to that already destructive influence.

It is unfortunate, however, that we should allow ourselves individually and collectively to become so distracted by this war of nations, as to become oblivious to every other interest, personal and communal. Much has recently been written relative to the tendency on the part of employers of labor to sit tight and sip war news, and while the stirring-up which they have received has been intensely seasonable and productive of good, it cannot be denied that employees in their capacity as such, and in the opportunities at their disposal for rational enjoyment, have adopted a like and perhaps more aggravated attitude. The fact is that none of us have been or are attending to our business affairs as we should and, of necessity, where we call the tune we must pay the piper.

The panic with which our business interests were seized in the early days of last month has passed off, only to give place, however, to something more stunning and destructive still—the war fever. We seem to forget that the war in which we are involved has as its object the crushing-out of militarism among the nations of the world, and who shall deny that unless we take immediate steps to again put business on the pedestal, the present temper of our people will contribute to and establish a military regime in Canada, hitherto undreamed of, and in no sense desirable.

We need not, of course, be too rashly optimistic, nor our faith in men and things be so unbounded, as to believe that wars are going to cease when peace is again declared in Europe. This Canada of ours, like every other nation, should be prepared to defend, as it will yet without a doubt have to, both her rights and her very existence, a contingency she is at the present time utterly incapable of doing but, while this is all true, her industrial feature must be safeguarded both in its continuity of application and its progressive development, for by so doing, and only so, will the best interests and welfare of our people be served.

The General Market Conditions and Tendencies

This section sets forth the views and observations of men qualified to judge the outlook and with whom we are in close touch through provincial correspondents.

Montreal, Que., Sept. 21, 1914.—In general the situation has not changed greatly in the last week. Iron and steel prices in the east seem to be holding their own. Certain lines of manufacturing, are, however, benefitting directly from the war, and there are others again whose business does not seem to have suffered materially as a result of it. One example of this is the Consolidated Rubber Co. of this city who have recently declared a quarterly dividend and, at the same meeting, the directors stated that they expected to operate their factory full time all during the winter without any reduction in staff.

The metal market seems to remain fairly firm. Prices have weakened, perhaps a little, but the general aspect is pretty firm. Should the present battle terminate in a decisive victory for the Allies the business situation would immediately become much better.

Steel Market.

Prices in the steel trade remain firm, although, owing to the fact that a great deal of construction work throughout the country has been stopped, the demand for structural steel has not been very great. The general depression of business has also greatly reduced the sale of bars of machinery steel. The quotations that dealers make are all for immediate acceptance and the steel offered is largely of American manufacture. However, there is in Canada a great deal of British steel in stock. The small volume of business has tended to keep the prices from fluctuating. Some mills have made slight advances in certain lines, while others have advanced different lines. Thus quotations on the American product may incline to vary a little.

Pig Iron.

The pig iron market is still dull. The grey iron foundries have been feeling the depression almost more than any other branch of the metal industry and thus the pig iron market has fallen more or less flat. There is still on hand here a considerable quantity of British pig iron but the demand for it is light. Prices have been unchanged for several weeks.

Machine Tools and Supplies.

The machine tool market continues quiet. Frequent sales are reported but they are usually of small units. The supply business is still fairly brisk but orders here are also small.

Metals.

Prices of metals remain fairly steady, although some are a trifle weaker than last week. Tin is steadily falling as the deliveries are of sufficient size to supply the light demand, but at thirty-four cents a pound it is comparatively high.

Toronto, Ont., Sept. 22, 1914.—Business conditions this week indicate a somewhat brighter tendency, although it cannot be said that trade has improved to any material extent; however, a more optimistic spirit prevails. We are steadily recovering from the acute depression following the outbreak of the war, and were money to become easier there would be a distinct revival as the business community is taking a calmer view of the situation, and is therefore more inclined to act along more nearly normal lines. The exchange market is easier than it has been at any time since the war began, and the money market should therefore be less stringent and export trade be benefited.

The recent success of the allied forces in Europe is no doubt responsible for the greater degree of confidence in mercantile circles but it will be some time before normal conditions may be expected. The improvement in trade con-

ditions will be gradual and in the meantime, manufacturers will be able to adapt themselves to the changed situation. There seems to be no doubt but that openings for new business will develop in due course, to a substantial degree. Sir George Foster, Minister of Trade and Commerce, has stated that as a direct result of the war, new business was already coming to Canada, orders having been received from Great Britain that formerly went to German firms. He also stated that Canada, with the other Dominions, would get the first opportunity of filling orders from the Old Country. From this source alone, the possibilities of securing new business are distinctly bright.

The British Empire Industrial League has recently been founded for the purpose of assisting in the establishment of additional industries and factories in the Dominion. Committees are being formed in the different cities to help in the work, and no doubt much good will result. The Department of Trade and Commerce is also devoting all its energy to furnish information to help in the movement to increase the trade of the Dominion. In order to obtain full benefit from the opportunity afforded, manufacturers must lose no time in taking advantage of any business that is offering, and in which they are interested.

Steel Market.

No change of any moment is noticeable in the iron and steel market this week, although the outlook is brighter. A certain amount of new business arising out of the war has been booked, notably by the Dominion Steel Corporation, which has received orders for 2,000 tons of nails and 2,000 tons of wire rods from England. We understand that negotiations are pending in another direction regarding an order for nails. This is an interesting development which may be the forerunner of a considerable amount of new business.

The Grand Trunk Railway has issued an order that all supplies will in future be purchased in Canada or Great Britain. This will have a stimulating effect on certain lines of steel products, seeing that in the past large quantities of steel tires, car wheels, tubes, etc., were obtained from Germany. With sufficient incentive to lay down plants to manufacture new lines, Canadian mills will be able to expand their business, at least in some products, even if they cannot compete in all lines. The Dominion Government has placed a large order for shells which has been distributed among five firms, and there is a possibility of further orders being given out. This is a new line of business, and will keep the companies concerned, busy for a time at least.

There is some building being done, but not enough to create much demand for structural shapes. Prices on steel products are being maintained, notwithstanding the fact that there is little demand. A Government order for 10,000 tons of rails for the Intercolonial Railway is being held as a nucleus pending the development of other business. Consumers appear to be holding off until the outlook improves and the financial stringency moderates.

The war is having a depressing effect on the steel trade in the United States and the dullness which exists is perhaps more pronounced than last week. Prices all round are being maintained, but there is little probability of any advance under the present conditions.

Pig Iron.

The pig iron market is extremely dull and little business is passing. Foundries and steel mills are very slack and consequently are buying very little iron. The Canadian Furnace Co. have blown out their furnace at Port Colborne on account of the dullness in trade.

Machine Tools.

The machine tool market is quiet, a few orders only being placed for single machines. There are a number of inquiries about, which has improved the outlook. We understand that specifications have been sent out for tools for the new dry docks at Owen Sound and Sault Ste. Marie, and the Department of Militia has ordered from a local dealer some machine tools and supplies for motor truck repair plants which are being equipped. The Department has also purchased locally a large number of motor trucks and truck bodies; among the former are included special trucks fitted out as repair shops.

Machinery Supplies.

Slightly improved business is noticeable in machinery supplies. Consumers who had held off during the past few weeks are now buying necessary supplies to satisfy immediate requirements. There has been no further change in prices.

Metals.

The metal markets are all quiet and the demand is comparatively light. Prices are steady, there being no changes from last week. Tin is steady, although it is possible that a further decline may be experienced, as there appears to be little difficulty now in obtaining this metal. The export of tin from England is now permissible. Spelter is steady, with a tendency to weaken. The New York and London metal exchanges are still closed.

St. John, N.B., Sept. 19, 1914.—Although somewhat upset when the first news came of the war troubles, manufacturers and proprietors of industrial plants throughout the province, are now settling themselves to face the outcome with calmness and determination. Many houses have lost some of their best help by the call for volunteers, but in most cases they have generously allowed them to go with an understanding that their position will remain awaiting them, and with a liberal arrangement as to pay. "Thus far," said one big industrial man this week, "we haven't lost such a great deal of business since the war broke out. Collections are not quite up to the standard, and we are shutting off on slow pays, but for the most part affairs with us are moving along as though there were no war. We are impressing upon our travelers the necessity of their refraining from reference to the war when on the road, and should a customer bring the matter up, they are advised to depreciate any thought of poorer business because of it. My belief," said he," is that Canadian manufacturing firms are going to experience an era of progress such as they had never dreamed of because of the crippling of the European industries, but its coming will be regulated by the duration of the war."

General Activities.

J. B. Cudlip, manager of the Cornwall & York Cotton Mills Co., here, said this week that business conditions were very satisfactory. Preparations are now being made by his big plants to handle an immense output of finished material. A slight depression was noticeable in the business at the outbreak of the war, but this was now lessening, and there is already evidence of advancement foreshadowed by the loss of German trade, in the manufacture of finished cottons.

The work of erecting a new main building for the LaTour Corn Mills in Carleton, to replace the plant destroyed by fire some months ago, is well advanced. The intention is to have the machinery soon installed and operations begun in the near future.

The plant of the Canada Wire Nail Works in West St. John is just about ready for output work. Horseshoe nails were cut in it this week. The outlook is for good business.

Some of the lumber mills about the city have been closed because of the war and the difficulties in the way of shipping, but the majority have continued sawing throughout, and anticipate a huge demand for their products later. Crews are being now engaged for the annual winter activities in the woods and many portable mills are being established.

By the 1st of November the steel arch for the new bridge at the reversing falls, St. John will be completed. The Dominion Bridge Co. will soon be able to set the first panel in position on the east-

ern anchors of this million dollar steel structure.

It is possible that a floating elevator may be built at St. John this fall to replace temporarily the loss sustained by the burning of the I.C.R. elevator recently. The Government has announced, however, its intention of replacing the former building by a larger concrete structure, with modern machinery to be installed.

A fourth high speed clam shell grab for reclamation purposes is expected in the city from a firm in Montreal in a few days for work on the new wharves being built at West St. John. This will greatly increase the efficiency of the larger plant now in operation there.

NEW CANADIAN BUSINESS.

Sir George Foster, Minister of Trade and Commerce, stated that as a direct result of the war, new business was already coming the way of Canada, orders having been received from Great Britain that formerly went to German firms.

Sir George also stated emphatically that nine-tenths of the stories going around to the effect that orders were being placed in the United States which could be filled in Canada, were pure fiction. In fact, he said, in every case the British Dominions are being given the first opportunity by the Motherland to fill orders, but of course, there were some requirements which Canada could not supply.

With regard to the capture of German trade, Sir George said that while already some firms had shown considerable enterprise, and were doing business which used to go to German firms, there were not the efforts being made that might have been expected.

Trade Gossip

The Canada Iron Corporation, Fort William, Ont., has been awarded the contract for cast iron pipe by the city of Winnipeg.

Keith's, Ltd., Toronto, will supply all the refrigerating equipment for the new artificial ice plant of the Montreal Arena Co., Montreal.

Keith's, Ltd., Toronto, have been awarded the contract for the refrigerating equipment of the new Central Technical School, Toronto.

The General Supply Co. of Canada, Ltd., Ottawa, has been awarded the contract for supplying a Trench rammer by the city of Ottawa.

The Northern Electric Co., Toronto, has been awarded the general contract for cable and wire, etc., for complete separate line to Dominion Chain Co., Niagara Falls, Ont., at $4,000.

The A. B. See Electric Elevator Co., of Canada, Ltd., Toronto, has obtained the contract for two elevators for the Merchants Bank of Canada, Montreal.

The Bain Wagon Co, Woodstock, Ont., has received an order for transport wagons from the British Government. The wagons are of special design to suit service conditions.

The Massey-Harris Co. are building at their Toronto plant 135 motor truck bodies for the Department of Militia. The bodies are of exceptionally substantial construction, and are made of oak.

The A. R. Williams Machinery Co., Toronto, have been awarded a contract, by the Militia Department, for three motor car repair outfits. Each outfit consists of a 20-in. drill, band saw, forges, and a number of small tools.

The Canadian Fairbanks-Morse Co., Toronto office, have received an order for the complete transmission equipment for Soren Bros., new factory on King street West, Toronto. Skefko patent double row, self-aligning, ball bearings will be installed throughout.

The Dominion Government has placed a large order for shells, which has been distributed among the following firms: Canadian Allis-Chalmers, Ltd., Toronto; Goldie, McCulloch Co., Galt; Jenckes Machine Co., Sherbrooke; John Bertram & Sons Co., Dundas, and the Chapman Double Ball Bearing Co., Toronto.

To Advertise Canadian Goods.—The Canadian Manufacturers' Association have decided to expend a large sum on a newspaper advertising campaign to place Canadian-made goods before the Canadian public. The publicity is to be displayed in the leading papers across the country and to start in the immediate future.

Suspension of Patents.—An Order-in-Council has been passed under the provisions of the past war session, conferring on the Minister of Agriculture power to suspend or cancel patent rights held in Canada by citizens of an enemy's country. The Minister is empowered to use his discretion in dealing with the patent rights in question, and may award them for a period extending to six months after the close of the war to any bona fide applicant. Similar action has been taken by all the belligerent countries.

Canadian Locomotive Co.—In submitting the annual report of the Canadian Locomotive Company, President Aemilius Jarvis said in part: "The decrease in profits as compared with those of the previous year is accounted for by the smaller output of the works as a result of the curtailment of orders by the Canadian Railways.

"During the whole of last year the trade of Canada has been steadily diminishing, consequently the railways' present equipment is ample for their existing mileage and needs. For this reason, added to the difficulties of obtaining money, many good orders from the railways have been postponed. On the other hand, a large amount of railway mileage in Canada is fast reaching a point of completion, to operate which additional equipment must be required. As our new plant is now practically completed, we will be in an exceedingly advantageous position to take care of new work when it is offered.

"At the present time, however, I have to report that the company is practically out of orders. The directors, foreseeing this situation, have for some time past kept the company in a strong financial position so as not to jeopardize the payment of interest and fixed charges. This is evidenced by the statement of liquid assets shown in the balance sheet, which amounts to $686,782, with quick liabilities of $139,806, or net liquid assets of $546,976."

War Grist

G. T. R. to Give $100,000.—The Grand Trunk employees in Montreal have decided to contribute the sum of $12,000 to the local branch of the Patriotic Fund. This will be but a portion of the contribution made by the men of the big railway system, as smaller gifts are being arranged for at the various traffic centres along the line, the money donated pasing through the local patriotic funds. With the Grand Trunk employees' co-operation, the amount contributed by the officers and general staffs will probably reach a total of nearly $100,000.

Steel Shells.—The Nova Scotia Steel Co. are going ahead with preparations to manufacture a large number of steel shells for the British Government. While the shells are not such as will run into heavy tonnage, they will provide a considerable amount of employment, and greatly help out in that direction. It is a matter of congratulation that the company's product of raw steel is so good as to conform in every test with the requirements for these shells, and a success in this branch will no doubt lead to further orders along other lines of military equipment.

F. A. Jacobs has severed his connection with The Mechanical Engineering Co., of McGill St., Montreal, and is succeeded by F. Ditchfield, who is now president and general manager.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News.

Engineering

Galt, Ont.—The building for the gas purification plant at Glenwood has been completed, and machinery is now being installed.

Guelph, Ont.—The Taylor-Forbes Co. have started their factory working on practically full time, and all their old employees have been notified to get back on the job.

Macleod, Alta.—Friction between City Engineer Altham and the Natural Gas Co., has terminated in the gas being removed from the city power house, and coal furnaces being re-installed.

Port Colborne, Ont.—The Canadian Union Furnace Co. have found it necessary, owing to the scarcity of work and the decrease in demand for their product, to lay off their men for a time at least.

Sidney, N.S—Some activity is being witnessed in connection with the Dominion Iron & Steel Co., according to recent reports. It would appear that the company is getting a share in the business formerly sent to Germany.

Redcliffe, Alta.—Mr. McKellis, of the Imperial Brass Co., Chicago, expects to visit Redcliffe shortly with regard to the consideration of tenders which have already been received for the construction of the company's new plant here.

Manufacture of Shells.—A Canadian commission has been appointed to inquire into the feasibility of the manufacture of shells in Canada for the Canadian and British field artillery guns, and a meeting was held at Valcartier recently. The members are: Thos. Cantley, general manager Nova Scotia Coal & Steel Co.; Col. Bertram, Montreal; Geo. W. Watts, Lieut.-Col Lafergie and A. G. Carnegie, Toronto.

St. Thomas, Ont.—A special meeting of the Board of Water Commissioners, was held at the city hall last Thursday morning to consider tenders for the work of installing boilers at the waterworks. Two tenders were submitted as follows: H. M. Morton, $1,230; J. S. Belbin, $1,343. The tender of H. M. Morton was accepted on the understanding that he give satisfactory security for the completion of the work.

Swastika, Ont.—Shipments for the month of August, outside of the Cobalt silver field, consisted only of gold and nickle. The Tough-Oakes Mine which is producing high grade gold ore at a phenomenal rate, shipped 61,680 pounds to the smelter at the latter end of the month. Over a million pounds of nickel ore came from the Alexo Mine at Iroquois Junction. While the war has seriously crippled the nickel market, the Mond Nickle Co. continues to produce, and as the Alexo ships to the Mond it may be said that this property will still be able to market its product.

Electrical

Bolton, Ont.—The tender for the $9,500 Hydro debentures was awarded to the Bolton Light, Heat & Power Co. at a special meeting of the village council. Their price was $9,215.

Fairbanks, Ont.—A deputation has been appointed to interview R. J. Fleming, of the Toronto Electric Light Co., as to the possibility of obtaining street lighting facilities for the district.

Kingston, Ont.—J. M. Campbell has offered to supply 700 horse-power of electrical energy to the city from Kingston mills at ¾ of a cent per killowatt hour. The offer will be put to a vote of the people.

Simcoe, Ont.—The bonds for Hydro-Electric extension to Simcoe have been sold. Work will commence at once, and the current is promised by November 14. If possible, the circular annex of the old gas plant will be used as a transformer station. The foundation and walls are in excellent condition.

Galt, Ont.—The installation of the ornamental street lighting on Main St. commenced on Sept. 16, when a gang of men was placed at work cutting out a strip of the cement sidewalk along the curb on the north side, where the conduit to carry the wires will be placed. The work will be rushed along as fast as possible.

New Toronto, Ont—At a meeting held on Sept. 14, the Hydro Commission resolved to extend the street lighting service into Etobicoke Township along the Lake Shore road, as far as Brown's line, about one mile from where the present service ends. This will give street lighting a little beyond Long Branch and also supply lighting for domestic purposes to Lake Shore Gardens and several streets running off the main route.

Municipal

Montreal, Que.—All work on the new filtration plant has been suspended until the spring.

Belleville, Ont—The tender of Wm. McGie of $1,975 for installing a new heating plant in the city building was accepted. The tender was the lowest.

Humboldt, Sask.—A by-law will be prepared providing for the raising of the sum of $5,000 to cover capital expenditure for electric light extensions.

Regina, Sask.—The Provincial Government propose spending $500,000 on road work, which will be executed by farmers who are the victims of crop failure, and are in need.

Winnipeg, Man.—The Manitoba Legislature has adjourned after a four days' session, in which the new loan for $2,000,000, to be expended on public buildings, was approved.

Kingston, Ont.—Dr. Amyot and J. A. Dallyn, of the Public Health Department, Toronto, opened the new sewage plant at Rockwood Asylum on Sept. 19. The works are considered to be the most modern now in existence.

Toronto, Ont.—A busy session of the Scarboro' Township Council was held on Sept. 14. Hydro Radial by-law, to be voted on October 19, was given its second reading. Taxpayers will be asked to vote that the township guarantees the bonds of the commission for $567,000 of the total issue of bonds.

Montreal, Que.—By a vote of 29 to 1 the City Council at a special meeting on Saturday rejected the recommendation of Mayor Martin and Controllers Herbert and Cote, to purchase the plant of the Montreal Water & Power Co. at $8,000,000. The only alderman opposing the council vote was Alderman Turcot.

Vancouver, B.C.—H. H. Stevens, M.P., on his return recently from Ottawa, announced that the Government would carry on to completion all public works under way in this city. While new undertakings will be restricted to those absolutely necessary, the Dominion Government will not curtail the public work in any other way.

Peterborough, Ont.—At the meeting of the power committee on Sept. 15, Mr. Robinson, of Toronto, general manager

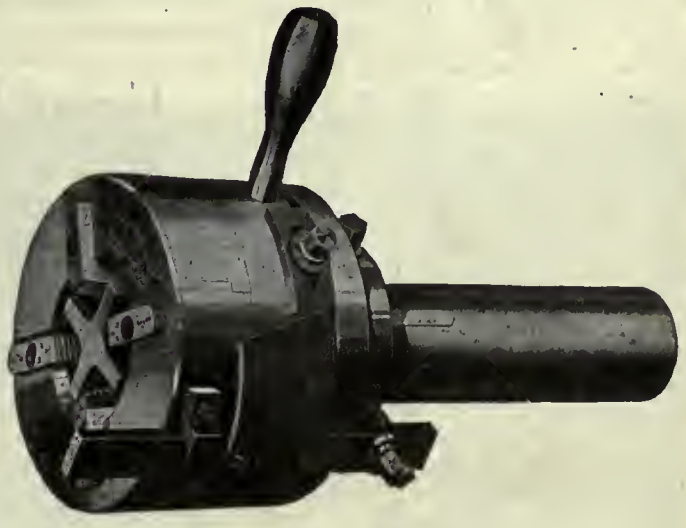
Special Faucets, Corporation Cocks, Beer Cocks, Locomotive Wash-out or Mud Plugs All Easily Threaded with

Geometric Taper Threading Die Heads



These Die Heads are specially adapted to Screw Machines and Turret Lathes.

Made to order, specially fitted to requirements of machine and work.

The Chasers follow the taper of the work **automatically,** and release the work at the end of the cut. Head is withdrawn without touching the finished threads.

When not cutting taper threads, the Head can be removed, leaving the Machine free for other work.

Consult us about your taper threads.

The Geometric Tool Company, New Haven, Conn.

Canadian Agents:
Williams & Wilson, Montreal. The A. R. Williams Machinery Co., Toronto and Winnipeg.

of the Peterborough Light & Power Co., and W. H. Munro, local manager of the same company, were present and requested the city to stay their move of taking over the Peterborough Light & Power Co. till November 1, so as to enable the company to divorce the Radial Railway Co. and settle all accounts.

Hamilton, Ont.—In regard to the necessity of a larger reservoir on the Mountain, a conference was held recently between the members of the Board of Control and the local Hydro Board, at which it was practically decided to secure an expert engineer to give an independent report as to the cost and benefit of such a reservoir. The cost of the engineer's fee will be shared by the Board of Control and the Hydro Board.

Toronto, Ont.—With work yet to be commenced on the new Union Station, Postoffice, Customs House and viaduct, Mayor Hocken intends going to Ottawa shortly, to urge the Federal Cabinet to force the contractors or responsible parties to make an early start, in order that employment be given to the men wanting work in the city. He will further ask the Government to consider the payment of the unemployed who enlist for home defence.

Toronto, Ont.—At a meeting of the city council last Mondal several by-laws were passed providing for the issue of debentures to the amount of $1,284,343 for the financing of the following public works: New Registry Office, $433,000; new Technical School, $654,879; buildings at the Industrial Farm, $81,860; civic car barns on Danforth Avenue, $65,488, and $49,116 for the establishment of a cold storage plant in connection with the civic abattoir.

Hamilton, Ont—Although the proposal was frowned on when the controller brought it up at the board some time ago, there is every prospect of the city going ahead this winter with the construction of an east-end sewage system. The total estimated cost is $110,000, of which the people pay $30,000 and the city $80,000. One point, however, which will have to be considered is the claim of the city engineer that to do the work in the winter will cost about forty per cent. more.

Ottawa, Ont.—The Provincial Board of Health has ordered that Ottawa go on with the Sir Alex. Binnie's water scheme, that is the 31-Mile Lake source of supply instead of the Ottawa River filtered water plan. The council of the Capital is given two weeks to go on with the work. Mayor McVeity, however, is prepared to fight to the last in favor of the filtration idea and will likely appeal to the Provincial Secretary against the ruling of the board. In a vote on the question the electors defeated a by-law favoring the drawing of supply from the lake, though the council favored it.

Sherbrooke, Que.—In answer to an invitation from the Industrial Committee of the Sherbrooke Board of Trade, the leading manufacturers of that city met on Sept. 18 at the office of the Board to discuss the question of trade expansion at home and abroad. D. J. Steele, chairman of the Industrial Committee, presided. The secretary placed before the meeting information which he had received from various sources. This included letters, blue books and reports from the Department of Trade and Commerce and from the Customs Department, as well as a most interesting letter from the Hon. W. S. Fielding, editor of the Journal of Commerce, Montreal.

Ottawa, Ont.—The Ottawa City Council on Sept. 14, went on record against the Ontario Board of Health giving any further consideration to the Thirty-one Mile Lake water scheme, at an estimated cost above eight million dollars, and insisted on the board adopting the plans prepared and approved by the most eminent engineers on the continent. Messrs. Hazen & Whipple, and George W. Fuller, of New York, of which the carrying out will cost about $2,000,000. The plans of Messrs. Hazen & Whipple are for Ottawa river water filtered. Council instructed the Board of Control to go ahead with the Ottawa river works in order to provide employment during the coming winter.

General Industrial

Toronto, Ont.—Prack & Perrine, of Hamilton, are the architects for the Wm. Wrigley Co. new factory.

London, Ont.—The International Fireworks Co., of Schenectady, N.Y., has decided to establish a branch here.

Collingwood, Ont.—The Collingwood Evaporator, owned and operated by James Vansise, was totally destroyed by fire on Sept. 20. The loss will amount to $3,000, uninsured.

Redcliffe, Alta.—G. M. Griffin, of Owen Sound, Ont., visited Redcliffe recently on a trip through the West. It is stated that he may establish a factory for making iron beds there.

Saskatoon, Sask.—It is reported that the Dominion interior elevator at that city will be ready for operation about September 15. The capacity of the present initial unit is 5,000,000 bushels.

Brantford, Ont.—The Slingsby Mill Co. have received two orders for a large consignment of blankets to be used as war supplies, while the Adams wagon works have just received a third order for their service wagons.

Lindsay, Ont.—If the plans now being considered by several interested outside parties take definite shape, the local mills owned and operated until recently by the Canadian Cereal & Flour Mills, Ltd., may resume operations at an early date.

Brantford, Ont.—The Verity Plow Co. has received word that a steamer has been secured for through shipment of implements to Australia. This will enable the company to send out shipments, orders for which had been received here, and the work on which had been done to some extent before the war broke out.

Petrolea, Ont.—Factories here are all working either full time or overtime and the town was never in a more prosperous condition. The Petrolea wagon works, one of the town's leading industries, is working thirteen hours a day to keep up with its orders. The Lambton Packing Co. is working overtime and the two big oil refineries, one of which supplies thousands of gallons of kerosene to the Government, are very busy.

Woodstock, Ont.—At a special meeting of the Board of Trade and citizens held on Sept. 17, to discuss the granting of a loan of $50,000 to the Oxford Knitting Co., to bring to Woodstock the woolen department of the Shawinigan Cotton Co., of Three Rivers, Que., it was decided that a committee consisting of Mayor Hobson, W. J. Taylor, president of the Board of Trade, and councillors W. S. West and J. E. Fidler be sent to Three Rivers to investigate the matter and report to the council before placing the matter before the people.

Hamilton, Ont.—The announcement was made by Industrial Commissioner Marsh, on Sept. 16, that within a month construction will start on the new building of the Proctor, Gamble Co., soap manufacturers of the United States, who are opening a local branch. Nine acres of land have been secured between the base line and the radial track, just west of Ottawa street, and with authority being had from the City Council and the Dominion Railway Commission to construct a switch and undertake other improvements, no time will be lost in rushing ahead the work. About four hundred men will be engaged when the plant opens. Over a million dollars will be spent on the new factory.

Railways—Bridges

Lindsay, Ont.—Fire broke out in the Grand Trunk station here last Monday. The building was partly destroyed, the interior being gutted.

Grey Iron and Car Wheel Foundries of C.P.R. Angus Shops

Staff Article

It were only natural to expect that the foundry layout and equipment, materials employed, methods adopted, efficiency and economy of production achieved, would be at least commensurate with the other departments of this, the principal new and repair work plant of the Canadian Pacific Railway. That such is the case, a perusal of the accompanying article amply bears out.

THE Angus shops of the Canadian Pacific Railway Co. are among the largest of their kind on the American Continent, and are by far the largest industrial shops in Canada. They are situated in Montreal toward the northern limits of the city, on rising ground, and command an uninterrupted view of the eastern portion of the city and the river beyond.

There are two separate foundries in connection with the works. They are known as the Grey Iron Foundry and the Car Wheel Foundry. The C.P.R. use all steel wheels on their passenger coaches, and cast iron wheels on their freight cars; but as the latter vastly outnumber the passenger coaches, the quantity of wheels required from the car wheel foundry is of necessity large. All of the cast iron that enters into the construction of the locomotives and cars is made in the grey iron foundry. In the days when most cars were constructed of wood, a great deal of cast iron, especially malleable castings, was employed in their construction, but, since the era of the steel car has dawned, less and less cast iron is used in this connection. However, the larger locomotives, and the greater number in use, have tended to equalize matters, and the volume of work has remained about the same. Of course, in the recent dull times a great falling off has been experienced. The freight business of the company, however, has not suffered in the same measure as the passenger traffic, and, as a consequence, the wheel foundry continues to run at nearly full capacity. The Western wheat has to be moved, and this business usually taxes the capacity of the railways, so at present it is desired to have all the rolling stock possible available for use.

Grey Iron Foundry—Sand.

The sand used in this foundry is delivered in cars and shovelled into the sand storage department. There are two kinds of sand used—the Hamilton and South Amboy. The former is shipped direct to the works in cars, while the latter is conveyed by water to the city wharves, and there transhipped into cars and hauled to the foundry. Hamilton sand is used for the lighter classes of castings, including bench and snap flask work, while the larger and heavier work is all done in the South Amboy sand. From the sand storage the new sand is conveyed to the floor in wheelbarrows and introduced as required. Some of the burnt sand is conveyed to the core room, where it is used in the central portions of the larger cores. Burnt sand is also used in the making up of cupola bottoms. Eventually it finds its way to the dump.

Patterns and Core Boxes.

All patterns are stored in a building adjacent to the foundry. No pattern is ever destroyed unless the type of locomotive or car of which it forms a part has become obsolete. Thus the number of patterns which have accumulated is enormous, and the system of caring for these patterns and keeping track of them is a more or less elaborate one. They are often of a more or less irregular construction, and care must be taken to prevent them from becoming warped. Each pattern is numbered and so classified that it can be located on a moment's notice. The foreman pattern maker is responsible for all patterns.

All special core boxes are stored with their patterns. When a pattern is required from the pattern vault an order

GENERAL VIEW OF INTERIOR OF GREY IRON FOUNDRY.

is placed on the foreman pattern maker by the foundry, giving particulars of the pattern required and the store order number to which the casting is to be charged. Thus, when a pattern is issued to the foundry, its core boxes accompany it. The foundry clerks receive their orders from the office, and, after receiving a pattern, attach to it a card giving full instructions to the moulder, who in turn fills out blanks on the card regarding his time and other remarks that may be necessary. While a pattern is in the sand, the cores are being made, and in this way the cores are always ready to be placed in the moulds when these are completed and ready to be closed up.

Nearly all the patterns are made of No. 1 white pine. They are varnished with shellac, cut in alcohol, and colored with lampblack. Other patterns are made of white metal and aluminum. These metal patterns are, however, used largely for brass and malleable castings which are not made in the Angus foundries. There are also some patterns of cast iron, but these are limited in number. When the cast iron patterns are used, it necessitates the use of a crane in drawing, for if of any size they are naturally so heavy that if drawn by hand bad results are almost sure to follow.

Flasks.

The size and construction of locomotives have made such rapid strides in the last quarter of a century that a large variety of patterns has accumulated. To mould many of these special flasks have been constructed. These flasks have all been preserved and are stored in the yards. They are preserved until the patterns for which they were made have become obsolete. The great majority of the flasks are made of cast iron. However, when a pattern will only be used for a few times at most because of its being of special design, a wooden flask with metallic pins and fixtures is constructed. There are many of these wooden flasks. Several carpenters are kept constantly employed changing flasks or putting in special bars in copes and other similar pieces of work.

When special anchoring out of the sand in a cope is required many little ideas are applied to make the anchored part solid. Thus, often there is considerable work entailed in fixing up copes and boxes. This work is of a varied nature, and is under the direct supervision of the foundry foreman.

EXTERIOR OF GREY IRON FOUNDRY WITH PATTERN STORES ON LEFT.

EXTERIOR OF GREY IRON FOUNDRY SHOWING SCRAP PILE.

Very little snap flask work is done, and only a small amount of bench work is required. The reason for this is that locomotives are not built in large numbers, and there are relatively few small or light parts of cast iron. There are, however, three moulding machines installed. Many of the larger flasks can be made to take various patterns by making small alterations in the drags and copes of the boxes. In this way it is contrived to reduce the exceedingly large number of flasks that would otherwise accumulate. The flasks are all classified, and under the care of one man, who can at all times locate requirements upon short notice.

Core Room.

Adjoining the core room are seven core ovens, each equipped with a flat car, which rolls into the oven on tracks. The ordinary round cores are made up in a machine and kept in stock. Sizes from three-eighths of an inch to seven inches can be produced in this machine. In preparing the sand for making the cores, no flour is used. Several core compounds are used, experience having shown that some makes are better under certain conditions than others. A Blystone batch mixer, manufactured by the Blystone Mfg. Co. of Cambridge Springs, Pa., prepares the sand used in the larger cores. This machine is belt connected to a 3 h.p. Canadian General Electric Co. motor.

The Iron Feature.

Most of the scrap is obtained from the rolling stock turned in for repairs, and since the advent of the all-steel car

there has been, if anything, more of a surplus than a shortage of scrap iron. All scrap is kept out in the yard, although there is always a sufficient quantity for immediate needs kept in the small yard between the foundry and the pattern vault. This yard is equipped with a ten-ton Whiting electric travelling crane. In that portion of the yard served by the crane a considerable quantity of pig iron is also kept. The crane is also used for elevating coke and other materials to the level of the charging floor, and one of the numerous spurs which serve all parts of the yard, conveys all materials to a point where the crane can take charge of it.

There are three standard mixtures of grey iron used. The first is the "cylinder mixture" from which cylinders and other castings required to withstand excessive wear and great heat are made. It is the best grade and closest grained iron of the three. The second is called the "machine mixture." This is used for all castings which have to be finished on machines. The third is known as the "common mixture," and is used whereever a casting need not be finished with a machine or tool.

General Practices and Equipment.

The foundry has been equipped throughout practically by the Whiting Foundry Equipment Co., of Harvey, Ill. The main section has two 10-ton electric travelling cranes installed. One of these is of English manufacture, being a Royce crane; the other is a Whiting. Most of the ramming is done by hand. Air is however available throughout the shop, and is used mainly for blowing out moulds, spraying blackwash, and in the moulding machines and vibrators. There are four pneumatic air rammers used in the cylinder moulds and other large work.

Running along each side of the shop is a small narrow gauge track with turntables and cross tracks laid at various short distances. Ladles mounted on trucks are used to convey metal to the various parts of the shop in quantities up to one thousand pounds. From these truck-ladles, metal is poured into bull ladles and hand ladles. Various other ladles having capacities of 2½ and 5 tons are also used, but they are handled entirely by the overhead electric cranes. It is not often that a ladle of greater capacity than 5 tons is required, because about the heaviest casting produced is the cylinder casting and this, in the case of the larger locomotives weighs rarely over four tons. Some of the larger castings commonly made are superheater headers, cylinders, cylinder bushings, pistons, piston rings, cylinder heads, sand boxes, domes, smokestacks, foot-plates, driving-wheels, etc.

The large ladles are all equipped with a hand wheel and a train of gears for tipping. In the train of gears there is a worm and worm-gear, so that the ladle locks itself at whatever angle it is inclined. The smaller track ladles are tipped by hand. They have, however, a locking device which keeps them in an upright position while being transported about the shop.

Two jib cranes are provided for use in making cylinder moulds and other heavy work. These cranes are designed to lift 10 tons, and are operated by hand. The whole cylinder mould is in reality a dry sand core, and these cranes lift the whole moulds on the core oven trucks, when they are to be put in the ovens to bake. In other large moulds, these cranes are used for lifting the copes, drawing heavy patterns from the sand and such other work as requires a heavy lift applied slowly and for some considerable time. These cranes are made entirely of steel. The length of the radial arm is about 18 feet.

INTERIOR OF GREY IRON FOUNDRY SHOWING CORE ROOM.

Cupolas.

The foundry is equipped with two cupolas, one having a capacity of 12 tons per hour and the other a capacity of 22 tons per hour. There is also a 5-ton reverbatory air furnace, where more or less work of an experimental nature is carried on. The work is experimental in as far as the various percentages of carbon, silicon and other elements which enter into the composition of the iron are concerned.

The wind blast is supplied by a positive Root's blower driven by a 75 h.p. Canadian General Electric Co. motor. The blower operates at a constant speed and supplies the blast for both cupolas. The air is by-passed and is thus supplied to the cupolas at a constant pressure of 9 inches. Each cupola is fitted with six tuyeres through which the blast is introduced.

Castings.

The castings, after having been shaken out, are taken over to the cleaning room. All pieces up to 350 pounds in weight are put into the tumbling mills. With them are placed smaller castings, iron stars, etc., so that upon removal from the tumblers the castings are perfectly free from sand. Rough fins and burs are removed by emery wheels, of which there are several in the cleaning room. When ready to leave the cleaning room the castings are placed on trucks and conveyed to the various parts of the machine shop, where they are to be machined.

Employees' Welfare.

In no department has the welfare of the employee been overlooked. Lockers are provided with shower baths. The latter are very attractive and are used daily by all the employees. The plant has several lunch counters situated on its grounds, where the wants of the employees are well looked after at nominal prices. As well as the regular meal at a fixed price, there is also an a-la-carte service, which is often more attractive to some men. Thus in as far as wash rooms and shower baths and the noon lunch arrangements are concerned, the C. P. R. Angus shops are far ahead of the large majority of industrial plants.

C. P. R. WHEEL FOUNDRY.

THE car wheel foundry is an entirely separate establishment from the grey iron foundry. The Hamilton and the South Amboy sands are also used here, but they are mixed; two parts of South Amboy sand to one of Hamilton being about the usual run of the mixture. This has been found to give the best results.

Patterns.

There are three distinct types of wheels which are recognized as standard by the Master Car Builders' Association. These are the 625, the 675, and the 725 pound wheels. Another type is also recognized but it is more or less special—the 880-pound wheel. This type being very heavy, is only used on the largest cars, those with a capacity over 100,000 lbs. It is also used on locomotive tenders. Thus there are but few pattern types, although a large number of patterns of each type. The patterns are constructed of No. 1 white pine and varnished with shellac colored with lampblack.

Flasks.

As the work is of a standard nature and all wheels are chilled, the flasks are practically of the same design and built specially for the work. When the foundry is operating at anything like full capacity, the flasks are nearly all in use and there arises no necessity for storing them outside. As a matter of fact they are nearly always to be found on the foundry floor.

Core Room.

There are in connection with the core room three core ovens all equipped similarly to the ovens in the grey iron foundry. Here, however, no core compounds are to be found, flour being used exclusively. The reason is that the cores are swept up on cast iron shells and baked in the latter. When cores, into whose composition a commercial core compound has entered, are baked in iron shells, it has been invariably found that the core sticks to the iron so tenaciously that its destruction is caused by removal. Trouble of this nature has never been experienced with flour, hence its exclusive use here.

Methods.

Every moulder has a helper, and upon commencing work in the morning they first begin to mould. Between nine and ten in the morning the day's floor, which cosists of twenty or twenty-one wheels for each moulder and his helper is completed and the pouring is started. The moulder and helper pour their own moulds, shake them out while the castings are still red hot, and place them in the annealing pits. As soon as the lot of wheels are in the pits, the day's work is complete.

Cupolas.

There are two cupolas of 22 tons capacity each per hour. Only one cupola is used at a time. Thus each cupola is fired every other day, while its mate is idle. The vein is tapped from the cupola into large 10-ton mixing ladles, which are tipped by electric motors, being mounted on fixed trunnions. In front of them runs a small narrow-gauge track which conveys a train of truck ladles. These ladles are conveyed the length of the shop by means of the tracks, and are carried across the foundry by overhead carriers to the rows of moulds. Each ladle carries about one thousand pounds of metal, or sufficient to pour one of the heaviest wheels.

Iron.

The iron mixture consists largely of old wheels with a little pig iron and malleable scrap thrown in. The principal endeavor is to keep the iron low in silicon. The old wheels are rolled in from the yard and taken to a crusher where they are broken up. The charges are all carefully weighed up and taken to the elevators which convey them to the level of the charging floor. The coke is also unloaded from cars into coke waggons which are elevated to the charging floor by these same elevators. The average melt is about 120 tons per day.

INTERIOR OF GREY IRON FOUNDRY SHOWING CUPOLAS.

Both cupolas were erected by the Whiting Foundry Equipment Co. of Harvey, Ill., and the air blast is furnished by a positive Root's blower, which is driven by a 75 h.p. Canadian General Electric Co. motor. The air is also by-passed into the cupolas. Each cupola has six tuyeres through which the air blast passes. The iron is tapped first into the big mixing ladles, from whence it is poured into the track ladles and thence into the moulds.

General Practices.

Soon after the iron has set in the moulds, the wheels are knocked out of the sand and taken to the annealing pits. There are sixty-six annealing pits and each pit can treat twenty-one wheels. For four days the wheels are left in the pits to allow the annealing process to be completed. When the castings are removed from the pits they pass on to the cleaning room, where the cores are removed and the loose sand brushed off. Next the final inspection takes place and they pass on to the storage platforms in the yards, and from there to the machine shops as required.

Tests.

A test piece is cast from every fifteen ladles. These test pieces are cast in small iron moulds 6 ins. x 2 ins. x 1½ ins., and are tested only for the depth of chill. Other pieces are cast in sand moulds 1¼ inches square by 24 inches long. These pieces are broken between 12-inch centres.

Three wheels from out of every hundred are taken and subjected to various tests. The first test is a thermal test, the wheel being placed in green sand with flange downward. A circle of molten metal, 4½ ins. deep by 1½ ins. wide, is run around the rim of the wheel. When two minutes have elapsed from

the time pouring has ceased, the wheel is examined for checks, while another wheel is examined for depth of chill. All these tests are recommended by the Master Car Builders' Association.

Further tests recommended by this association are also applied to the car wheels. The tape test is perhaps applied in a somewhat different manner than by some other institutions. The nominal diameter of a car wheel is 33 inches and, to use the technical phrase, wheels are allowed to vary two sizes either way from their nominal diameter. A size represents about a 1/8 in. variation in circumference. All wheels are measured and their sizes marked; thus when pressing wheels on axles it is always endeavored to place wheels of the same diameter on the same axle. It is quite easily seen that wheels thus mated will wear a great deal longer than if there were an appreciable difference in their diameters. The average life of a wheel is about six years and, during that period it is estimated that it runs about 70,000 miles.

General.

In conclusion there is but little further to add. Both foundries are furnished with the very best of equipment and in regard to the conditions surrounding the employee we can safely say he has been in no way overlooked. The men under whose supervision the foundries have fallen are every one alive and progressive. Thus, with an excellent executive guiding the work, with the best of equipment and materials and a contented body of employees, there can only be one result—a product of high quality.

EXPLOSIONS IN ENGINE CRANK CHAMBERS

AMONG the explosions of various kinds that came under an inspector's notice, it is interesting to note the record of oil explosion in the crank chambers of high-speed engines. The inspector for the N.W. district of England reports three explosions of this nature—two in the crank chamber of gas engines, and one in the crank chamber of a steam engine in an electric generating station. Similar explosions have been reported in recent years, with fatal results, all of which occurred in engines of the enclosed type, with superposed cylinders, in which the engine framing is constructed as a hollow chamber to hold the lubricating oil in which the cranks, crank shaft and eccentric run.

A special oil with a flash point of 400° to 450° F. is generally used, and its constant agitation by the engine cranks not only raises the temperature (records in unventilated chambers show temperatures of 150° to 160° F.), but causes a fine spray or mist of oil to fill the chamber. This mist contains oil particles in such a finely divided state that it requires only a spark or overheated surface to cause ignition.

Explosions in crank chambers of steam engines have been caused by ignition due to defective lubrication and overheating of the slides. In gas engines, ignition may be due either to escape of heated gases round the trunk pistons, or to vaporized oil coming in contact with an overheated piston, or possibly to splashing of oil into the cavity of the trunk piston, where it dries and forms a deposit of carbon, which may become incandescent from an overheated piston, and thus ignite the oil vapour.

Removal of the combustible gases by means of plenum ventilation has proved the solution of the trouble with gas engines, but it is not clear if the same means would equally answer with steam engines, although plenum ventilation would reduce the temperature of the crank chamber. Percentage analyses of gases from the crank chamber of a gas engine, A before and B after plenum ventilation has been installed, are given below:—

ANALYSIS OF GAS ENGINE CRANK GASES.

	CO_2	CO	CH_4	H	O	Combustible Gases.
A	4.4	10.4	Nil	Nil	11.6	10.4
	0.4	Nil	Nil	Nil	19.6	Nil
B	0.2	Nil	Nil	Nil	19.6	Nil

Temperature of oil in crank chamber (B) 131° F.

Previous to the installation of plenum ventilation at the works from which the above results were obtained, both water cooling and natural ventilation (by connecting up the crank chamber to a mill chimney) had been tried, but neither method nor a combination of the two gave satisfactory results, and, after a further explosion, plenum ventilation was installed.

WHEEL AND RAIL FRICTION.

THE coefficient of friction between wheels and rails is a variable quantity, depending on the condition of the rails and the state of the weather. The author of an article in a German paper on this subject deals with the extent to which it is possible to utilize to the best effect any given coefficient of friction according as steam or electric traction is employed. With an ordinary steam engine with two cylinders, the torque is by no means uniform, and the coefficient of friction cannot be taken as being more than 1/6, having regard to the largest value of the torque, whereas with a similar electric locomotive, in which the torque is constant, the coefficient might be taken as 1/5.

The next question is as to whether the electric motor, either direct-current or single-phase or polyphase, can be rightly considered as having a constant torque, and this depends not only on the motor itself, but also on the methods of control and the various stages provided by the controller. Experimental work on the Prussian State Railways with regard to this point is described, and it seems that, generally speaking, the coefficient of friction with electric traction can fairly be taken as being 20 per cent. greater than that with steam traction.

ELECTRICAL PROTECTIVE DEVICES.

WRITING in the Vulcan of September, J Gardner says the protective devices installed in modern generating stations probably represent the highest standard of design and workmanship in the entire installation, and the cost of the switchboard frequently falls not far short of the generating plant it controls. In the old days, however, few or no protective devices were installed. For instance, in a power station still running there are several 2000-volt 300-kilowatt single-phase generators controlled by open single-pole switches of the simplest type and without even a fuse in circuit; one side of the system is earthed. Everything operates quite satisfactorily until a cable goes to earth or someone makes a mistake; then there is a serious accident.

A case of this kind recently occurred. A direct-current generator coupled to a steam engine was being run up in readiness for paralleling with other machines. When the volts were about 100, the attendant closed the main switch by mistake. Although the fault was discovered immediately, the rush of current into the machine pulled the armature winding partly round the core, and some of the commutator segments were nearly forced out of the V rings. The driving pins in the armature were sheared off and the insulation of the core was damaged. The armature had to be entirely re-wound and the commutator rebuilt.

Machine Gun Battery.—The machine gun battery mounted upon automobiles which has been financed mainly by the Hon. Clifford Sifton and was mobilized at Ottawa, has left for Valcartier. It comprises 15 protected high speed automobiles with quick-firing guns, automobile ambulances and machines for reconnoitering. The motor cars have a speed of 50 miles an hour and this unit will be one of the best and most efficient component parts of the Canadian division. The recruiting of the 150 men, all of whom are qualified chauffeurs, or mechanicians, has been attended to personally by Jack Sifton

PRODUCTION METHODS AND DEVICES

A Department for the Interchange and Distribution of Shop and Office Data and Ideas Evolved from Actual Practical Application and Experience

AN INEXPENSIVE BENCH GRINDER

By W. G.

THE small bench grinder herewith described was designed and made with the object of providing a simple and efficient machine, all the

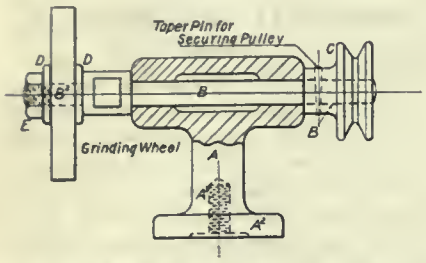


FIG. 1. INEXPENSIVE BENCH GRINDER.

work in connection with which could be done on a 12-inch screw-cutting lathe without the addition of special tools, fixtures, etc. The work for which the machine was made consisted of the grinding of the more delicate cutting tools for which the regular shop grinder was unsuited. The grinder must also be efficient, cheap and so constructed that duplicate parts can he readily made at any time.

Figure 1 is a part longitudinal section showing its general arrangement. Figs. 2 and 3 are detail views of the body casting, spindle, pulley and clamping washer respectively. The head stock, A, consists of a cast iron bracket of circular section as shown, which is bored out to a nice running fit for the spindle B. It will be noticed that the central portion of the said hole is recessed to provide clearance for the spindle and to facilitate boring. The base is also recessed for clearance at A^3, and the hole

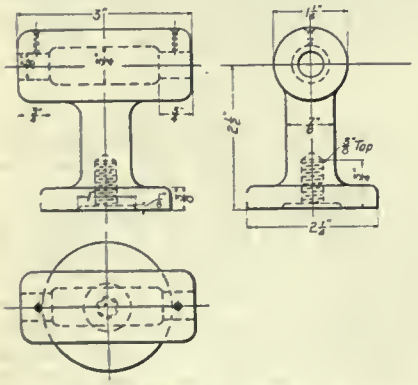

FIG. 2. INEXPENSIVE BENCH GRINDER.

A^3 is drilled and tapped for a stud. A stud has been found more suitable for this purpose than a cap screw as it is much easier to get the nut on.

The spindle part B, is made of mild steel and consists of a bar having at one end a reduced stem part, B^1, and at the other a screw neck, B^2, for the purpose of receiving the grinding wheel. This should be an easy running fit in the bore of the body catsing. The pulley is shown at C, Fig. 1. This is made of cast iron and is machined all over to preserve true running and balance of the spindle. The clamping washers, D, two of which are used, although constituting the simplest parts of the machine, should be made very carefully. These are made from the bar and are bored out and faced before being cut from off. The nut was faced on a mandril after being threaded an easy fit for the screwed part of the spindle.

After arranging for lubrication, either in the hollow of the body casting or by separate oil holes, the machine is ready to be assembled and put into service. Care should be taken to see that the wheel is not too tight on the spindle and

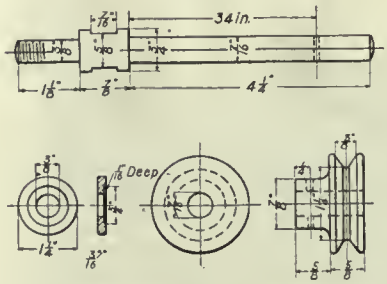

FIG. 3. INEXPENSIVE BENCH GRINDER.

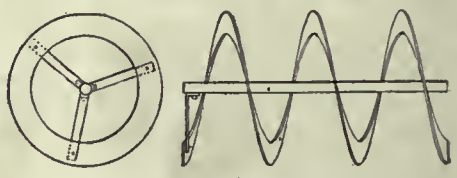
that it is properly trued up. This machine fulfilled the requirement of cheapness, and if required to be made in quantities, would easily lend itself to the operations of automatic machine tools.

SPIRAL CONVEYOR QUERY.

Will you please ask some of your readers through the medium of your journal to suggest the easiest and cheapest way of making the spirals for conveyors, as shown in the accompanying sketch. The spiral is made of wrought iron, 1 x ¼ in., is 18 in. outside diameter and 3 ft. long, having three complete turns in this length.

This is a repetition job, and is made in a large variety of sizes. The only tools at our disposal are the ordinary bending rolls, such as are used by boiler makers. Hitherto this has been largely a rule of thumb job, both in getting the correct diameter of coils and calculating the exact length of strip required for a certain number of turns and a given extension. If the tools mentioned are not applicable, the writer would like to know of the



SPIRAL CONVEYER QUERY.

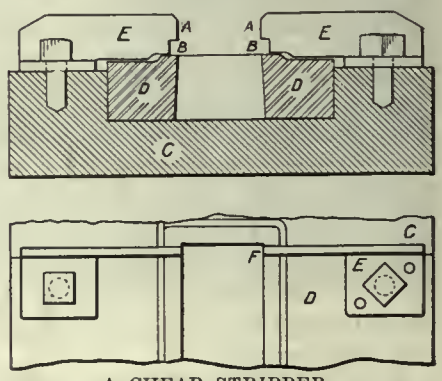
simplest possible device to satisfactorily do the work.—J. Davis.

A CHEAP STRIPPER

By X. Y. Z.

WHEN putting strippers on blanking dies for cutting round or rectangular pieces from a strip, it is usual to employ a plate stripper made of stock generally from ¼ to ⅜ in. thick. This must have a hole worked out to fit the punch, and must clear the strips that guide the stock. When the material to be punched is not too heavy, small pieces E E, as shown in the accompanying illustration, may be used instead of the plate.

The cast iron die shoe C carries the tool steel die ring D. The mild steel pieces E E are cut out and bent, as shown, and are fastened to the shoe by dowels and cap screws. These pieces serve not only as strippers, but guide the stock as well. The points A A just clear the punch, and the stock slides easily between points B B. When the punch rises after cutting a blank, these projections at A A strip the metal from the punch. Four of these are required, two on each side of the die, and, if the die



A CHEAP STRIPPER.

be square or rectangular, they should be located close to the corner, as at F.

The writer has found this method of stripping to work very satisfactorily on

round or square blanks, and has also used them on many odd shapes. The stripper also leaves the die and gauges always in sight of the operator, and enables him to turn out more work, as he can, at all times, see just what is going on. Pieces of scrap, which often clog the ordinary stripper, especially when narrow stock is used, can easily be removed, and the cheapness of the device is also a strong recommendation for its adoption.

EXHAUST HEADER WITH WELDED NOZZLES.

By F. K. Blair.

THE illustration shows an 18-in. exhaust header in the plant of the London Electric Co.,London, Ont., to which has been welded a 10-in. and 12-in. nozzle, the former being the exhaust connection from three high-speed engines, and the latter a connection to one of three condensers. In addition to the nozzles shown, which, by the way, came quite close to each other and at right angles according to the layout, numerous other 10-in. and 12-in. connections were made by welding, none of them, of course, being on piping subject to high internal pressure.

EXHAUST HEADER WITH WELDED NOZZLES.

The particular advantage derived from having the nozzles welded was that of getting connections close together where these were desirable, without the complications of crowded-up fittings and a multiplicity of joints. Perfect satisfaction of service is being rendered by the various joints, a circumstance more or less complimentary to Green & Sloan, Bredalbane street, Toronto, who carried out the work.

GAS POISONING.

THE following is an extract from a table made up from cases reported as accidents under Section 4 of the British Notice of Accidents Act, 1906, which serves as some guide of the frequency of cases of poisoning by gases:—

Nature of Gas or Fumes.	1913.	1912.
(1)	(2)	(3)
Carbon monoxide.....	59[7]	91[13]
(a) Blast furnace.....	20[3]	33[5]
(b) Power (suction producer, Mond, Dowson)	21	19[4]
(c) Coal	9[4]	29[2]
(d) Other	9	10[3]

The small figures relate to fatal cases, and are included in the principal figures.

Blast Furnace Gas.—Among the 20 cases with three deaths reported from blast furnace gas, eight occurred in charging at the cupola, eight from cleaning operations, mainly of flues, and three in repair work. One of the fatal cases occurred to a tar still man in an iron and chemical works who, towards the end of a double 12 hours' shift, retired to lie down on a bench in a small shelter fitted with a door and heated by means of the furnace gas supplied by a 1 in. pipe. When his father came to relieve him the man was found unconscious. The gas was turned on, but was out either as the result of fluctuation in the pressure or of the deceased's foot touching the tap. The door of the shelter was closed.

Power Gas.—Of the 21 cases, one occurred in starting the plant, two in stoking, twelve in cleaning or repairing, and six by escape of gas from a leak in the purifier. In one case the workman, knowing the danger, entered the scrubber through a manhole. In another, the workman chose to lie down to rest beside the engine.

BLUE PRINT QUERY.

I would much appreciate any information you can give me as to the causes and cure of our blue print trouble. We have a roll of sensitised paper and find that we cannot get clear white lines as we have done before. Upon a short exposure, we get blue lines and a pale blue backgrounnd and, on washing, the lines disappear. When the print is exposed for ten minutes, a white background with blue lines appears, which also washes out. The paper has been carefully stored in a dark room for some time.—G. Barrett.

Answer.—The first exposure mentioned is a little too short, and the ten minute exposure is certainly too long. About two and a half minutes in the sun should give good results. Many blue prints can be improved by over-exposure and dipping in a solution of bichromate of potash before washing.

The paper is probably too old. In winter time blue print paper will keep for two months if properly stored, but during the warm weather of summer, one month of usefulness is all that could be expected of the unexposed paper, and, if used after this, its behavior is liable to be erratic.

OXIDIZED FINISH FOR SHEETS.

IN the ordinary oxidation of iron or steel sheets by air, a deeply oxidized, hard light blue finish is secured which is said to be not always uniform throughout the surface, while ordinary oxidation by steam results in a superficially oxidized soft and dark blue finish. A patent (1,105,251, July 28, 1914), granted to John E. Carnahan, Canton, Ohio, has as its object the giving of such sheets a deeply oxidized hard and uniform dark blue finish. The new process consists in heating the sheets in an annealing box to an annealing heat and then separately exposing the heated sheets to the air. They are then again heated in an annealing box to a dark red temperature not sufficiently high to decompose the air-formed oxidation on them, after which they are permitted to cool while in the annealing box, steam being introduced into the box while they are both being heated and cooled. It is claimed that this further oxidation by the steam not only darkens the blue color, but renders it uniform, and that it serves to soften any excessive hardness from the previous oxidation.

OVERHAULING A DAMAGED THRUST BEARING.

IN a recent number of the Journal of the American Society of Naval Engineers there appeared the following paper covering the Overhaul of a Damaged Thrust Bearing, by Lieut.-Commander H. C. Duigen, U.S.N.

In the four-shaft Parsons turbine installation where a h.p. and i.p. cruising turbine are employed, the two cruising turbines being on the inboard shafts, there is considerable excess propeller thrust on the l.p. thrust collars, whose shaft also carries the i.p. cruising turbine, when going up to speeds near the limit of this combination. Under these conditions, with the propeller thrust taken on the lower shaft rings, the l.p. thrusts of the shafts that carry the i.p. cruising turbine are quite susceptible to heating, and this thrust has been burned out on several vessels. There is usually sufficient surface in the l.p. thrust collars, and the thrust will operate quite satisfactorily provided the bearing of a sufficient number of the collars on their surface is true.

On one vessel this thrust operated without trouble for a long period, until one day, when it was desired to speed up to 19 knots quickly, the thrust heated rapidly and could not be cooled till the combination was shifted so as to release the excess thrust and allow the rotor to move out. Previous to this, speeds as high as 20 knots had been run on this combination for long periods with thrust quite cool. In connection with this matter it has been noted that the rotor comes in harder, and there is considerably more propeller thrust when in shoal water. The worst condition for heating is therefore in speeding-up quickly on the i.p. combination in shoal water. When the vessel is by herself this condition can be avoided to some extent, but when in formation any speed called must be quickly given.

Revealing the Trouble.

On anchoring, the heated thrust was examined, and about six of the collars and rings were cut and roughened. The surfaces were cleaned and stoned; but as there were only a few hours available to do this work, a thorough job could not be made of it. On trying this thrust again on the i.p. combination, it again heated up at about 17 knots. During an overhaul week, a few days later, the thrust was carefully examined. The clearance on bottom rings and go-ahead side of collars was measured by feeler gauges, with shaft in position, at intervals of 90 deg. The readings conclusively showed that the surfaces of the collars did not run true. The heated collars also showed that the most intense heat was at one part of the circumference, and this was the same part of the circumference on all the collars. Squares and straight-edges placed on the surfaces of the collars also showed that the collars were far from being true, and that they were not parallel to each other or normal to the axis of the shaft.

Spotting the shaft collars with red lead and bringing the thrust wings up to bear, and then revolving the shaft also clearly showed that the collars ran out, and the collars that bore touched only in spots on one side. The flange of the thrust shaft was trained to see whether the shaft ran out. The differences for different points of the circumference were so slight that it was apparent that the shaft itself was not bent. From the measurements taken it appeared that the surfaces of collars had not been machined true, but that there had been sufficient bearing surface to allow the thrust to run cool till, on account of some special circumstances, due perhaps to speeding-up quickly, an excessive load was produced and the heating resulted.

Remedying the Trouble.

To remedy the defective conditions, the following procedure was adopted:—The lower thrust-block shell carrying the rings taking the go-ahead propeller thrust was carefully cleaned up and put in place. The surface of the collars was carefully covered with red lead, the thrust brought up to touch, and then the shaft revolved. The first spotting showed number 6 collar to bear hard in two spots, and about five other collars bearing slightly in streaks for about 40 deg. on one side. The spots were then filed and the spotting process repeated. The second spotting showed about eight collars bearing in streaks part of the way around. The third spotting showed about ten collars bearing in rather heavy streaks about half-way around. Filing was then stopped, as it was feared to take off too much metal, and time was also limited.

Grinding-in Process Adopted.

A novel grinding-in process was then tried. The lower thrust block was put in place. A dummy adjustment jig which permits of rotors being moved in or out with a ratchet gear was rigged over the thrust collars to keep rotor in place. A mixture of bathbrick and oil was put on the thrust bearing and the turbine rotated at about 25 revs. with steam. The collars were brought to bear by means of the jig, and were moved up slightly tighter as the grinding proceeded. The supply of powdered bathbrick and oil was continually replenished while the grinding was going on. The brickdust and oil ground the surfaces in contact and tended to smooth them up. As the collars are of hard steel and the thrust rings of composition, most of the grinding would be done on the rings, however, some grinding and smoothing-up of steel surfaces would also result. This grinding was continued for about 2½ hours. The thrust block was then taken out and all parts of rings and collars carefully cleaned and replaced. After these adjustments were made, the thrust, though regarded with suspicion, ran satisfactorily up to nearly 18 knots on the combination for nearly three months, but on another occasion when necessary to speed up quickly in shoal water, it again heated badly.

The vessel arrived at the navy yard shortly after for a two weeks stay, and thus an opportunity for more carefully overhauling the thrust presented itself. The shell containing the rings was taken to the shop, and the edges of countersinks and all oil grooves were carefully milled out and the surfaces carefully smoothed up. The surfaces of collars were carefully dressed up with file and scrapers by two navy yard mechanics especially expert at this work. Then the process of spotting the collars with red lead and filing down high spots was repeated, but this was done more often than on first attempt. The work took two machinists six days.

When this spotting and filing had progressed so far that a fair bearing was obtained on most of the collars, and all the collars touched at some points, the surfaces were again ground in a bath of oil and brickdust for about three hours, running the turbine with steam at about 30 revs. per min. Everything was again carefully cleaned out. The process of cleaning out, spotting, and filing, and finally grinding-in, ensured surfaces being smooth. When the thrust was tried soon after this to the practical limit of the I.P. combination, it operated satisfactorily. This method of grinding-in a bearing is perhaps somewhat novel, but it appears to be quite effective, and accomplishes what might otherwise require a large amount of labor.

The Electric Vehicle.—Dr. Charles P. Steinmetz, of the General Electric Co., than whom there is no one who can speak more authoritatively upon the subject, predicts that within ten years there will be in operation not fewer than one million moderate priced electric vehicles whose approximate price will not exceed $500 with a speed certain to average 20 miles per hour. Against the gasoline cars he claims the disadvantages of fuel and oil costs, the concentration necessary in driving a high-powered machine and the need of constant attention to its engine. "Within a decade," he says, "the gasoline car will be relegated to the limbo of things outlived."

DONT'S FOR CUPOLA USERS.

By "Melter."

DON'T use a straight clay with fire-brick for cupola, but mix one part of clay with two parts of moulding sand which is more refractory than clay alone and possesses sufficient bond.

Don't skimp on the workman's tools; there should be two brick hammers, one 3-pound hammer, two small chisels, two steel bars, three water pails, one moulder's shovel, one straight-edge, two soft daubing brushes, two trowels, one slag hole pin, one tapping hole pin, two torches, two cupola picks, three bars for freeze-ups, one hoe, four hole stoppers, six tapping bars, one rammer, one ladder, and one broom.

Don't have the ends on hole stoppers of greater diameter than the bod or difficulty will be experienced in making the bod stay on the stick when cutting into the top of metal stream.

Don't leave the metal in the wind box exposed. Line it with silica sand and fireclay to a depth of one-half inch which will save the material and facilitate the removal of any iron which may be spilled into the box.

Don't use gangway sand for the cupola bottom for, if there be a large heat, the iron will cut. Use a mixture of new molding sand two parts, old molding sand two parts, core and gangway sand one part.

Don't put in too big a tapping hole; 1½ ins. diameter and 6 ins. long is large enough for any cupola. If brest is over 6 ins. long, cup it out on the inside. For a brest mixture use moulding sand, white sand and fire clay in equal parts.

Don't let freeze-ups bother you, put a bod on the inside of tapping hole when putting in the bottom.

Don't be afraid of using too much wood when lighting up or, the iron will be cold. Make a frame box 4 ft x 4 ft. x 8 ft. for a 72 ins. diameter cupola to hold each day's requirements, and see that it is all thoroughly dried. Wood should be from 8 to 18 inches above top of tuyers and uniformly laid flat around cupola.

Don't put on all the remaining bed coke after the first has burned through but, as soon as cupola gases are ignited fill up places where bed has burned, and wait until the whole is cherry red and then charge evenly.

Don't throw in charges any old way, but put large pieces in first, then pack smaller pieces in holes and around lining, particularly well over tuyeres. Steel should be charged on the coke because it is there in closer contact with the carbon which it absorbs—after red heat—about 1,500 degs. F., until the melting point of cast iron is reached.

Don't use too heavy a first charge of iron. It should weigh not more than 3½ times the weight of the bed coke.

Don't skimp on the bed coke, but rather cut the coke charges down after the first three. Sometimes a ratio of as much as 11 to 1 can be maintained.

Don't be afraid to increase coke if cupola is oxidizing excessively which will be noted by the condition of slag. If cupola be running right, the color of the slag will be brown, and if it is oxidizing in excess the color will be black, due to the excessive pressure of iron and manganese oxide. This oxidation can also be noted by an examination at the tuyeres and charging doors, and the conditions carefully noted.

Don't slag when you feel like it, but do it with consistent uniformity, and the iron will be of more uniform temperature and analysis, also freer from dirt.

Don't stick on the blast because it gives hot iron. Melt no hotter than is actually required, because the hotter one melts the greater the size of graphite flakes and the weaker the iron. Too hot iron possibly means more oxidation than is necessary; silicon and manganese cost money. Putting on blast will increase temperature to a certain point, after which there will be no further increase, but meanwhile the lining is being cut excessively.

TURBINE VS. GAS ENGINE FOR STEEL PLANTS.

SPEAKING before the Chicago Section of the American Institute of Electrical Engineers on "Power Problems in Steel Mills," F. G. Gasche made pointed reference to the shortcomings of the gas engine as an exclusive prime mover for steel mill service. Mr. Gasche's remarks were directed particularly to the four-cycle twin tandem type of large capacity, driving alternating-current generators. The unsuitability of this type of prime mover for exclusive use, granting that under steady load conditions the gas engine has enough advantages to warrant its supplying a part of the power required, was based in part upon the following facts:

THIS, HERR STRUTT IS ONE OF OUR LATEST AND MOST EFFECTIVE QUICK FIRING GUNS!
A WORKING MODEL OF ONE OF THE GREATEST TRIUMPHS OF MODERN ENGINEERING WHICH WILL DOUBTLESS INTEREST YOU HERR STRUTT
THIS MEINHERR IS ONE OF THE LATEST PATTERNS OF SOLID STEEL RIVETS, AS USED IN MODERN BRITISH DREADNOUGHTS

A VOYAGE OF DISCOVERY.

Being an artist's idea of what an eminent German gentleman saw during his recent visit to British shipbuilding yards.—*Journal of Commerce.*

Investigation has not yet given sufficient data for determining accurately the extent of the loads thrown suddenly upon the prime movers in steel mills,

particularly motor-driven mills. Supplying sufficient space capacity in gas engine units to carry these peak loads is accordingly a matter of guesswork, and especially so because the regulation of the gas engine of the type under discussion is hopelessly inadequate to the instantaneous character of the mill load variations. The weight that is required to be put into fly-wheel and rotor parts to equalize the load is entirely out of proportion to the effective capacity of the units, and the drag resulting from the inertia of these moving parts makes the question of adequate regulation impossible of satisfactory solution. The variation in torque inherent in the gas engine of this type as a prime mover, even under ideal conditions of constant load, is another essential handicap to its harmonious adaptation. The addition of the storage battery for the absorption of the peak loads, to the gas engine plant at some of the steel plants, does not provide a sufficiently flexible nor economical regulator of the load to offer a solution of the difficulties.

Mr. Gaschè ventured the suggestion that a design of prime movers for a steel mill might provide 70 per cent. of the capacity in gas engines and 30 per cent. in steam turbines, in which proportion the probability of the power plant adapting itself to the load conditions would be improved in every respect. Against the future development promised in the field of the gas engine, the possibilities to be realized in the use of superheated steam, in the range of temperatures above 700° F., were regarded as even more attractive.

REPORT ON BOILER EXPLOSION.

THE Department of Public Works, Province of Ontario, has issued through its Steam Boiler Inspection office, the following report covering the explosion of a portable agricultural type boiler at Kinmardine, Ont., on September 11 of this year.

Description of Boiler.

The boiler, as already stated, was of the portable agricultural type, with internal furnace, and rated at 10 or 12 horsepower. The shell, constructed in one course, was 39 ins. in diameter by 6 ft. 6 ins. long, of 5-16 in. plate with longitudinal seam, double riveted lap; the rivets being 5-8 in. diameter by 2¾ in. pitch. The heads were 5-16 in. thick, and the circumferential seams had ⅝ in. diameter rivets of 2½ in. pitch. The rear head was stayed to the combustion chamber head by ¾-in. screw stays pitched at 6 ins. by 6 ins. maximum. The furnace consisted of one course 21 ins. diameter, 60 ins. long. ¼ in. plate with longitudinal seam single riveted lap, and ⅝ in. rivets, 2¾ in. pitch. The tubes were 2½ in. diameter and numbered twenty-three. The segments above tubes were stayed by two 1-in. through stays. The boiler mountings were of the usual type, the safety valve diameter being 1½ ins. This was manufactured by the Consolidated Valve Co., Connecticut. A single-cylinder horizontal engine was mounted on top of the shell and the outfit was manufactured by L. D. Sawyer & Co., Hamilton. The date of manufacture was not obtainable.

Condition of Boiler After Explosion.

The furnace had ruptured and collapsed about three feet from the front end, tearing circumferentially. The longitudinal seam was on the bottom of the furnace and the rupture passed through the centre of a rivet-hole. The bottom half of the furnace at the point of failure was forced up to the crown and was torn about half way around the circumference. The plate was wasted around the mouth of the furnace to a knife edge in many places and pitted and corroded generally to a material depth which could not be gauged owing to the condition of the furnace at the time of inspection. The engine and mountings were all smashed more or less, with the exception of the safety valve, which was intact. The steam gauge dial was missing, but the movement, which was of the double tube type, was not damaged, and appeared to be in sound working condition.

Remarks and Conclusions.

The explosion was undoubtedly due to the failure of a furnace weak in construction and weakened and impaired by age and corrosion, and altogether totally inadequate to withstand the working pressure of 100 pounds per square inch carried at the time of the accident. Owing to the nature of the collapse, the thickness and condition of the metal at the ruptured part could not be ascertained without the furnace being removed. The safety valve was tested after the accident and a report of this test from Hergott Bros., Mildmay, shows that it released at 110 pounds per square inch.

The boiler was blown by the reaction of the explosion about 100 feet from its original location through the woodwork of a barn, causing considerable damage to property and the loss of the owner's life. Samuel Lindsay, besides inflicting very serious injuries to the deceased man's father and another victim, a farmer, who was assisting to run the threshing machine at the time of the disaster.

It is obvious that this fatal explosion could have been avoided had the boiler been examined by a competent man and the working pressure fixed in accordance with the strength and condition of the boiler structure. The boiler had only been in operation at the already mentioned farm for a very short period and had been previously purchased in a second-hand condition from some person in this line of business.

We are indebted to D. M. Medcalf, chief of Boiler Inspectors' Department, Province of Ontario, for the report and photographs.

Series of Practical Questions and Answers for Mechanics

Every care is being taken to include only pertinent, practical questions, and give same direct reliable answers. Catch questions will be avoided. Arithmetic, consisting of simple addition, subtraction, multiplication and division of decimals, will be found a most useful companion

Question—The pressure on the piston of a steam engine is 30,000 pounds; the length of the stroke is 30 inches and the distance from the center line of the connecting rod to the center of the main bearing is 18 inches. What sized shaft should be used?

Answer—In this case it is necessary to determine the combined effect of twisting and bending, and reduce both to either bending or twisting moment.

Equivalent bending moment = $Mo + \sqrt{\frac{Mo^2 + Mt^2}{2}}$ where Mo = bending moment and Mt = twisting moment.

Mo = 30,000 / 1b = 540,000 : Mt = 30,000 / 30

— = 450,000 equivalent bending moment.

2

$$= 540{,}000 + \sqrt{\frac{540{,}000^2 + 450{,}000^2}{2}}$$

$$= 540{,}000 + 382{,}475 = 922{,}475$$

$$\text{Formula} = \frac{M}{S} = \frac{I}{c}. \quad M = 922{,}475.$$

S = 10,000

$$I = 1964 : c = \frac{d}{2} : \frac{I}{c} = \frac{.1964d^4 / 2}{d}$$

$$= .0982d^3$$

$$\text{Formula becomes} \frac{M}{S} = .0982d^3 \text{ or } d^3 = \frac{M}{.0982S}$$

$$d^3 = \frac{922{,}475}{.0982 / 10000} = 93{,}935 : d = 4.38 \text{ in.}$$

Use in this case 4½-inch shaft.

• • •

Question—Will a pump lift hot water? If not, why?

Answer—No. Theoretically cold water can be lifted about 34 feet. As the temperature is raised this height is decreased until at or near the boiling point it cannot be lifted at all. The reason is that the hot water easily changes to steam at the lower pressure of the suction and this steam instead of solid water fills the cylinder of the pump.

• • •

Question—What is the method of procedure in setting the valves of a Corliss pump?

Answer—First take off steam chest cover and set both cranks same exactly [illegible]. Measure carefully the width of steam ports and place hook valves centrally over ports. Set up just safe to remain half the width of the ports from the valves and lock them in this position. Valves should move in opposite directions to open ports. Replace covers and pump is ready to start.

• • •

Question—A hydraulic wheel press is driven by two eccentrics directly connected to a 20-in. pulley. The diameter of one plunger is 2½ in. and of the other 2 in., and the common stroke is 2 in. If the effective pull on the belt be 30 lbs. what pressure could be obtained on the ram with either eccentric?

Answer—The possible pressure on the plungers is the same as 30 lbs. on a 10 to 2 leverage or

$$\frac{30 / 10}{2} = 450 \text{ lbs.}$$

Area of ram = 10² / .7854 = 78.54 sq. in.

Area of small plunger = 2² / .7854 = 4.908 sq. in.

If pressure on plunger were 1 lb., pressure on ram would be

$$\frac{78.54}{4.908} = 16.$$

Therefore with belt pull of 30 lbs. pressure on ram is 16 / 450 = 91,800 lbs. or approximately 91 tons.

Area of large plunger is 2² / .7854 = 3.1416 sq. in. 1 lb. pressure on large plunger would give

$$\frac{78.54}{3.1416} = 25 \text{ lb.}$$

With belt pull of 30 lbs. or 450 lbs. on plunger pressure on ram is 25 / 450 = 11,250 lbs. or 5.6 tons.

• • •

Question—If the speed of the driving pulley be 200 r.p.m. what would be the speed of the ram (a) using small plunger only, (b) using both plungers?

Answer—Speed of small plunger is 200 / 2

$$\frac{\text{area of plunger}}{\text{area of ram}} / 20 = 12.5 \text{ ft. per min.}$$

Speed of ram = $\frac{4.908}{78.54} / 20 = 1.25$ ft. per min. (a)

With both plungers working at 12.25 ft. per min. speed of ram is

$$\frac{\text{combined area of plungers}}{\text{area of ram}} / 20 = \frac{8.9084}{78.54} / 20 = 1.32 \text{ ft per min.} \quad (b)$$

or 5 times as fast.

• • •

Question—A mast stays in 10 feet right to the point where the guy wires are attached and the ground ends of the wires are fastened 100 ft. from the base. The strain on one cable is 30,000 pounds. What are its horizontal and vertical components?

Answer—The hypotenuse of a triangle whose sides are 10 and 100 is $\sqrt{(100^2 + 10^2)} = 100.5$ ft. The length 100.5 represents the pull of the cable. The vertical component is represented by 10 and the horizontal component by 100.

The horizontal component is then.

30,000 : 100.5 : x : 100 or x

$$= \frac{30000 / 100}{100.5} = 29850.5 \text{ pounds.}$$

The vertical component is

$$\frac{30000 / 10}{100.5} = 2985.2 \text{ pounds.}$$

• • •

Question—Taking the diameter of the earth as 8000 miles and that it rotates once in 24 hours, what is the speed in miles per minute of a point at the equator? What would be the speed of a point half way between the equator and the pole?

Answer—Circumference of earth = 8000 / 3.1416 = 25,132.2 miles. No. of miles per minute

$$= \frac{25132.2}{24 / 60} = 17.453 \text{ miles.}$$

The radius of a circle halfway between the equator and the pole = 8000 / the sine of 45 degrees = 8000 / .7071 = 11313.44 miles. Circumference = 11313.44 / 3.1416 = 35,527.4 miles.

Speed per minute

$$= \frac{35527.2}{24 / 60} = 24.674 \text{ miles.}$$

• • •

Question—What is the rim speed of a 36-in. pulley when running at 250 r.p.m.?

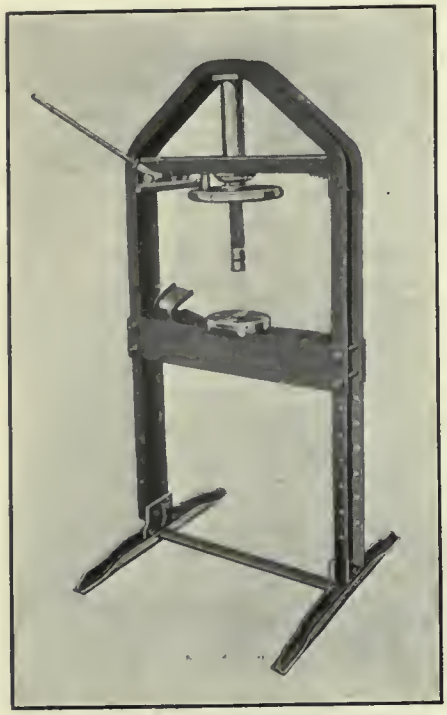
Answer—Circumference of pulley = 3 / 3.1416 = 25,132 ft. Rim speed = $\frac{25.132 / 250}{60}$ = 104.7 feet per second.

PROGRESS IN NEW EQUIPMENT

A Record of New and Improved Machinery and Accessories for the Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

GARAGE PRESS.

WHILE this press is capable of handling practically all classes of machine shop work it has been designed especially to meet the demands peculiar to the auto repair shop and garage.



20-TON GARAGE PRESS.

The frame is in one piece of 5-inch by 2-inch channel steel, there are as a consequence no joints or connections to weaken the construction. A heavy hand wheel, 15 inches in diameter provides quick action for ordinary light jobs, and for securing the maximum pressure, the lever construction, shown in the accompanying cut is employed; providing a leverage of 1,500 to 1 and enabling the maximum pressure of 20 tons to be accomplished with ease.

The bolster which carries the plate is readily adjustable for height upon the uprights of the frame. The maximum adjustment is 48 inches between plate and bottom of screw. The screw is two inches in diameter with 3 pitch Acme thread. The weight of the screw rests upon bronze thrust bearings which enable the wheel to spin the screw up or down quickly. The screw has a range of movement of 12 inches. The distance between the uprights of the frame is 32 inches, which permits the press to accept the largest automobile wheels. A vice attachment for holding round or irregular pieces is provided which permits of a great variety of application. A varied equipment of blocks is also furnished with each press.

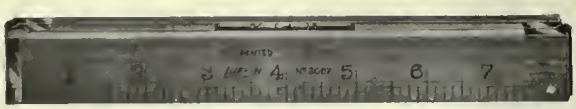
The following are among the number of applications to which the press is adaptable:—Straightening shafts and axles; pressing wheels on and off shafts; compressing leaf springs for assembling; pressing bushings on and off; straightening frames and rear systems; broaching holes; pressing ball races on and off shafts; cutting key-ways in pulleys; bending and shaping angles, bars, etc.

The Weaver Mfg. Co., Springville, have put this tool on the market, and in its strong, compact and powerful features gives every indication of amply fulfilling the purpose of its design.

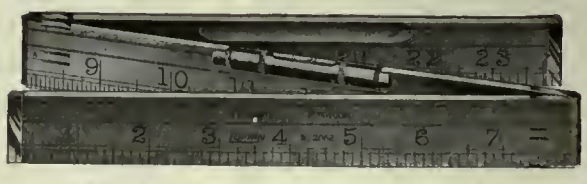
COMBINATION POCKET RULE AND LEVEL.

THIS product is a 2-ft. folding boxwood rule fitted with a spirit level. The three 8-inch rule sections are each 1 in. wide, 3-16 in. thick and are united by substantial brass joints. The rule is fully graduated its entire length both sides, one side inches to eighths, and the level is neatly set into and flush with the upper edge of the middle section of the rule where most convenient for use and is securely protected by the two outer sections of the rule, which fold against it on either side when closed for carrying in the pocket. The combination rule and level being light and but 8 in. long when folded, is conveniently carried in the pocket. Closing pins especially designed for the purpose hold the sections of the rule in proper alignment insuring a perfect bearing surface. The accuracy of both rule and level is guaranteed.

The Lufkin Rule Co. of Canada, Ltd., Windsor, Ont., are its manufacturers and patents are pending.



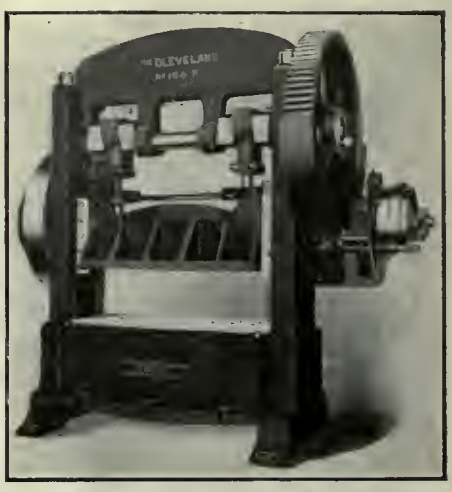
COMBINATION POCKET RULE AND LEVEL.



COMBINATION POCKET RULE AND LEVEL.

HEAVY PATTERN DOUBLE CRANK POWER PRESS.

THE heavy pattern double crank power press shown here is a recent product of the Cleveland Machine & Mfg. Co., Cleveland, Ohio. Several sizes have been developed, each of which is made in various widths between housings. The frame is "four piece," held together with heavy steel tie rods, while the length of the housings can be varied to suit individual requirements, giving die space from bed to slide, up to 72 inches. Where these extreme dimensions are necessary from crown fender and similar high dies, a special connection is furnished which permits adjustment of the slide through the whole die space and eliminates the necessity of using the auxiliary bed plates, ring bolsters, etc., for dies of normal sheet height. The slide-ways are also extended so that the slide never overhangs its bearings.



HEAVY PATTERN DOUBLE CRANK PRESS.

The machine is equipped with a powerful multiple disc friction clutch, with the operating links fully enclosed so that there are no revolving parts exposed. The adjustment is universal on all levers. The brake arms are operated by a pair

of toggle links and the clutch is controlled by a hand lever in convenient position for the operator.

The machine shown is 72 ins. between housings, has 3 ins. stroke of slide, and weighs about 35,000 lbs.

SAFETY WATER COLUMN AND STEAM SEPARATOR.

FIGURE 1 shows the operating mechanism of the Anderson safety water column with high and low water alarm. All of the working parts are assembled in the removable hanger frame A, which is secured in the body of the column by means of the pins G. When the water rises in the boiler to the high point, the float D strikes the top lever B, which draws the whistle valve M from the valve seat. At the low water point, the float strikes lever C, which opens the whistle valve through the link E.

These columns are made in different sizes, suitable for different sizes and types of boilers, and Figure 2 shows a section through column, the large sediment chamber in the bottom being noteworthy.

The Anderson steam separator is shown in Figure 3. This separator consists of the body with the outlet extending up about half-way through it. The head, which screws to the body, is fitted with a bell-shaped cone, to which is fastened a set of spiral baffles. The steam enters through the head, strikes the cone, and is given a spiral or whirling motion by the baffles which throws the moisture against the body, the steam passing out under the cone. The moisture is prevented from following the steam by the deflector at the top of the discharge opening, and is drained off through the globe valve at the separator bottom to a steam trap. They are made in all sizes from 1½ ins. to 12 ins., in both vertical and horizontal types, by the V. D. Anderson Co., Cleveland, Ohio., who are also manufacturers of the safety water column.

FIG. 1. OPERATING MECHANISM OF WATER COLUMN.

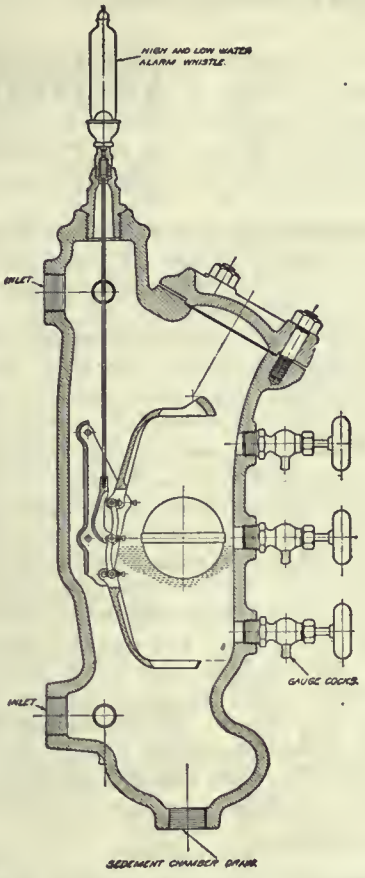


FIG. 2. SECTION THROUGH WATER COLUMN.

WORKMEN'S COMPENSATION ACT.

THE Workmen's Compensation Act comes into operation on January 1. The formal proclamation to that effect has been published, and sets at rest any doubts there may have been on that score. Every workman injured after the first of the year will be entitled to compensation as provided under the new Act.

In order to give employers ample time in which to prepare their statements as to pay rolls, etc., the board has decided to extend for a month the time for presenting these. The statements, which must show the total pay roll for the twelve months ending September 30, and give an estimate of the total pay roll for the calendar year 1915, can be submitted any time before the end of October. Forms can be obtained from the board after October 15.

Among the matters with which the board will have to deal are the questions whether the assessment on employers will be made on the actual pay roll for 1914 or the estimated pay roll for 1915; whether employers having only a very few workmen shall be excluded from the Act except where they choose to come under it; what rearrangements, if any, of classification of industries shall be made; and what rates shall be fixed for each class, and what method of subclassification or grading of different hazards shall be adopted.

In announcing their plans, the board intimate that because of the prevailing depression, employers will be dealt with as easily as possible. The chairman of the board intimates that, subject to the conditions that safe provision must be made for the payment to the workmen and their dependents of the compensation to which they are entitled, the board will endeavor to meet the wishes of employers as far as it feels it can properly do so in regard to arrangements for the collection of the funds and other details. It is quite realized that the industrial conditions of the province are far from being normal at the present time, and this fact will be carefully borne in mind.

FIG. 3. PHANTOM VIEW OF STEAM SEPARATOR.

Question and Answer Series for Foundrymen

Foundrymen having difficulties in connection with their work are invited to forward particulars of them to this department for solution. The greatest possible care will be taken to give only reliable and tried-out advice on all questions submitted.

Question.—Will you kindly give us a good formula for hot rolling mill bearings?

Answer.—The following formula has given very good results: Copper 90 pounds, tin 10 pounds, or try copper 85½ pounds, phosphor-copper (15 per cent.) 3½ pounds, tin 8 pounds, zinc 3 pounds.

* * *

Question.—We are anxious to secure a mixture for bushings required on a machine operated at a very high speed. These bushings vary from 2½ to 4½ inches in diameter, and are from 6 to 8 inches long.

Answer.—An alloy that can be recommended for this work is as follows: Copper 82 pounds, tin 10 pounds, phosphor tin (5 per cent.) 2 pounds, lead 6 pounds. This is an expensive alloy and will probably be too costly for your work. If so, you might try the following: Copper 66 pounds, lead 14 pounds, zinc 10 pounds, tin 4 pounds.

* * *

Question.—We are making steel castings and have considerable trouble in removing the cores from them, especially the small cores in the heavy sections. The cores seem to change into a mixture of silica and steel, and require considerable more time to be spent on their removal than should be necessary. We have changed the mixture of our core sand several times, with very little success. Analysis of the cores after such formation show about equal parts of silica and steel. We thought that probably the moisture in the cores was the cause of the crystallization, and used every precaution to keep them dry, but this did not overcome the difficulty. We would like to have a core mixture for small and medium cores that can be removed from the castings with the least amount of work.

Answer.—All steel foundries have more or less trouble in removing small cores from the castings when the cores are in the heavy sections, and if it were possible to make cores of silica sand about 98 per cent. pure, there would be very little difficulty. The foreign matter in the sand which is used for binding purpose fuses and causes the trouble. The idea should be to prepare a core with the least possible percentage of binding material, and have the skin of the core as free as possible from porosity. A mixture that has given excellent results for small and medium cores is as follows:—Silica flour tempered with molasses or glutrin. When the cores are dry, it is advisable to wash them with a mixture of silica flour and molasses or glutrin diluted with water.

* * *

Question.—We deliver the iron around to the smaller ladles on the different floors with a 1,000-lb. bull ladle, and experience considerable trouble with the daubing as it invariably falls off after it has been filled with the metal three or four times. Can you suggest anyway to overcome this difficulty.

Answer.—The cause of your trouble is due to the fact that the daubing on your ladle is not thoroughly dried before the ladle is used and steam is generated between the lining and the shell of the ladle which forces the daubing away from the shell. Clean your ladle and clay wash with a brush and use only enough clay water to hold your lining material together. A mixture for lining that has given good results is:—New moulding sand 2 parts; sharpsand, 1 part; fireclay 1 part. Too much fireclay in lining material will cause it to shrink and crack when drying.

* * *

Question.—Can you give us a first class formula for making modeling wax.

Answer.—Wax for modeling purpose can be made from the following mixture:—White wax 6 lbs., lard 1 lb., and zinc white 1 lb. Melt the wax at a low temperature, add the lard and stir in the zinc white and color with vermillion. Another good formula is:—White wax 20 parts, oil of turpentine 4 parts, sesame oil 1 part, and vermillion 2 parts, Melt the wax and stir in the turpentine gradually, add the other ingredients, then pour on to a slab or plate to cool; remelt and pour into tepid water and knead until plastic.

* * *

Question.—We would like a good mixture for red metal for making bond lugs. The metal must be soft, as the lugs are riveted to the rail.

Answer.—The following alloy is suitable for this purpose:—Copper 88 pounds, tin 3 pounds, zinc 6 pounds, and lead 3 pounds.

U. S. IMPORT AND EXPORT TRADE.

TREMENDOUS decreases in American export trade during August, resulting from war in Europe, are shown in detail by comparisons of the Department of Commerce with the business of one year ago. Export trade to Germany practically came to a standstill, while that to France and Great Britain, where shipping has not been so seriously interrupted, showed only a comparatively small decrease. Trade to Belgium, and that to Argentina, which depends largely on foreign shipping, suffered heavily.

The decrease in the August export trade to Europe as a whole amounted to $58,320,619. That represented in a large measure the decrease in credit abroad as employed to offset American obligations. The falling off in exports reached more than $77,000,000. One year ago in August the total was $187,909,200, compared with $110,369,240 last month.

The effect of war upon American import trade was not so great. Last month it amounted to $129,767,890, compared with $137,651,553 in August, 1913. The imports from Germany and Great Britain did not show as large a decrease as those from France. The decrease from Europe as a whole was about $17,000,000.

Manufactures showed the largest decrease in exports among the various groups. Foodstuffs almost maintained their level of one year ago.

TRADE WITH GREAT BRITAIN.

THE following are official figures of trade between Canada and Great Britain in the undermentioned articles during August:

Imports From Canada.

	Aug. 1914	Aug. 1913
Wheat	£1,506,011	£868,255
Wheatmeal and oatmeal	147,889	144,539
Oats	85,797	37,578
Barley	97,395	75,999
Bacon	129,404	65,893
Hams	21,380	24,857
Cheese	739,930	649,590
Canned salmon	2,948	22,202
Canned lobster	53,622	45,176

Exports to Canada.

Spirits	54,359	43,885
Wool	16,767	6,743
Pig iron	869	6,975
Wrought bars	911	5,286
Galvanized sheets	18,241	33,875
Tinned plates	5,402	11,262
Steel bars	7,143	23,309
Cutlery	6,037	8,944
Hardware	10,596	10,159

Charles E. Mackenzie, manager of the Winnipeg office of the Canadian General Electric Co., and Canadian Allis-Chalmers, Ltd., died on Sept. 21, at his residence in Winnipeg, ager 42. Mr. Mackenzie was a nephew of Sir William Mackenzie, president of the C.N.R.

BUSINESS AS USUAL?

ONE of the most popular slogans arising out of the European War, at least in the commercial and industrial sphere, is that of "Business as Usual." Just why the interests concerned have appropriated the phrase is not at all clear, neither is it reassuring, for may it not actually be the outcome of a desire to simply put a "face" on conditions that more or less demand it. In one sense, "Business is as Usual," and in another sense it is otherwise, and our relative position to one or the other determines whether we are in earnest or bluffing.

In prosperous or boom times little effort, comparatively speaking, may be expended to keep the factory wheels and a myriad of employees taxed to the limit to serve the demand, and this condition may be to a large extent existent in quite normal times. Is it not possible, however, that in spite of the tremendous upsetting events of the past two months, we still are disposed to "take" what is offering and let what needs "getting" go by; in other words, we are conducting our business as "usual" and there is no bluff about it.

Having said this much on behalf of what is undoubtedly a minority of commercial and industrial enterprises, it may be safely inferred that the majority are quite insincere in the use of the "Business as Usual" slogan. They have in many cases withdrawn themselves completely from the public eye, and what is perhaps more condemnatory still, because absolutely without reason or justification, they have decided that the particular sphree to which they had the privilege of catering needs meantime no attention.

The great trouble to-day is that we are all too pessimistic. We act, however otherwise we may talk and write, as though the European Anti-Burglar Alliance was unequal to the task it has set itself. In grasping hold of the bee, we seem somehow to get the sting instead of the honey. In trying to pluck the rose, our portion seems to be the thorn, and our upward look sees nothing but the dark cloud, although the silver lining is there.

Business, notwithstanding, is as "Usual," by which is meant that there is business to be got, but the amount of our share will be entirely dependent on the enterprise and energy we put forth to get it. This is neither a normal time nor yet is it a boom time, to the latter of which unfortunately we have become too accustomed. It is an abnormal time and the very antithesis of a boom period. Conditions are just such now that our industries should have every searchlight of publicity focussed on the path to their factory doors, but in how few instances is this being given effect to. It is insufficiently realized, and generally not at all, that the peculiar circumstances in which we find ourselves make it necessary for us to go after business more insistently and more strenuously than ever before. Our own and the needs of others still demand supply, and the wherewithal to produce and to purchase is just every whit as available as formerly if we go about our business affairs in the proper spirit and in a determined manner.

Declarations otherwise, notwithstanding, we have not got beyond the panic stage. Canadian business enterprise is simply seething with pessimism, born of a craven fear that the European Burglar may after all prevail. The adoption of such an attitude is contrary to both right and reason. No subject of the British Empire, if he be truly loyal, should have the slightest misgiving as to the ultimate outcome of this European struggle, for he who assumes the role of a coward is perchance not far removed from being a traitor. Again, and on the highest plane of approach to the ultimate issue, none of us worthy the name of Christain dare be pessimistic.

Let us get rid of all this pretence therefore of "Business as Usual," and turn it into reality by getting after and embracing the opportunities everywhere offering. Let us get into the firing line and throw out again our scouting forces, and where in normal times these consisted of a few scattered units, let us be strategic enough to see that such means are multiplied and increased in effectiveness.
